Another great disadvantage was the heat, which began to make itself felt as soon as the mines began to reach considerable depths, and gradually increased until on the 2840-ft. level of the Yellow Jacket the rock had a temperature of 154°F. and the air of the drifts reached 110°F. and higher. Nearly all the other mines were equally hot, and only a visit to the lower levels will convince one accustomed to the summer climate of New Mexico and Arizona that such temperatures are almost unbearable. Engineers who have come to examine the Lode have found their energies almost totally consumed in conveying them from one water-spray or ice-water tank to the next, and the efficiency factor of underground labor can readily be inferred. Conditions of work underground present surprises. The men drink liberally of ice-water, with no bad effects, though the

\**Mining and Scientific Press*, February 10, 1877.

casual visitor not unnaturally fears a congestive chill. At mealtime at some of the shafts the miners rush to the station, pull off their dripping garments, and put on others equally wet and are hoisted to the surface, where the temperature is 35 to 75° lower, to eat their dinners. It is not remarkable that, as the superintendents remark, after they have been up a little while they are glad to get back to work. A uniform wage scale of \$4 per shift is paid, having been put in force in 1867. Wages elsewhere have steadily risen, but not on the Comstock. The explanation is simple, the wage is 'what the traffic will bear.' A company which exists upon assessments is not a good employer from whom to demand an increase of wages. In 1880 and 1881 assessments amounted to \$12,041,590 and dividends to \$370,000. In 1910 the Comstock mines produced \$502,843 in gold, and in 1911 this rose to \$977,349, besides which in the latter 618,006 oz. of silver was shipped, according to figures compiled by the U. S. Geological Survey.

With men working for a moderate wage under arduous conditions it might be expected that only the lowest class of workmen could be secured. But the tabulation made by Eliot Lord in 1880 showed that of a total of 2770 workmen, 816 were Irish, 770 Americans, 640 English, 191 Canadians, 83 Scotch, and less numbers of other nationalities, only 14 being Italians and 1 Slavonian. This preponderance of the Anglo-Celtic element still holds good. To me it seemed that the fascination of a bonanza must appeal strongly to the imaginative Celt, else why should a skilled miner continue to work in what is a foretaste of Gehenna for the same wage as in other mines? The workmen I saw were of fine physique, but the training of a crew offers obvious difficulties where the shoveler receives the same wage as the skilled miner.

Will the Lode yield other bonanzas? Who knows! Thirty years of desultory work has not served to disclose them, and meanwhile the mines pour out an unceasing flood of hot water. J. A. Church, who advanced the theory that the heat is generated by the kaolinization of the feldspar in the eruptive, saw no hope that the mines would ever penetrate beyond the hot zone. The water is a heavy burden, and the earlier belief that it is derived from the vadose circulation is somewhat shaken by the fact that the water being pumped from the lowest level is as hot as at first, after thirty years of pumping. It must be said that if bonanzas can be found neither heat nor water will act as effective deterrents to their exploration. Not long ago a daily chronicler the story of a mine in the southwest where the owners, in their search for ore, were driven back by an inflow of water too great to handle. After a few years of inaction the directors came to visit the mine to devise, if possible, some means of reopening it. Lo, the mine was dry; the lowest levels were even dusty. Some geomorphic movement had opened new channels and drained away the water. The apocryphal story is typical of the spirit of the miner, at once the most practical and most mystical of men.

The Comstock is notable as well because it has contributed so largely to the development of mining in America. The Burleigh drill was perfected while driving the Sutro tunnel, and square-set timbering was devised by Philip Deidesheimer to support the wide stopes necessary in taking out the bonanzas. It is perhaps less generally known that I. L. Requa, the father of M. L. Requa, devised the first self-dumping skip for use in the Combination 4-compartment shaft, which, at the time it was completed, was the deepest and best equipped in the world. The Wheeler pan and the Washoe process were likewise products of the ingenuity called forth by the exigencies of Comstock conditions. The glory of the Comstock, like the glory of Israel, has departed, but it, like the ancient people, makes its influence felt in contemporary achievement.

THE Transvaal Miners' Phthisis Sanatorium building and equipment cost \$250,000, and has accommodation for 70 patients. Twenty-eight were in residence at the end of 1911. Maintenance of the institution for the term cost \$18,300.

## Mining in Western Australia in 1911

The annual report of the Mines Department of Western Australia is now at hand. Although the past year's work has been noted to some extent, the remarks of the Secretary for Mines, H. S. King, are of interest, as well as the corrected figures of mineral production.

There has been another decrease in the total mineral output which is being experienced by the other states of Australia. In spite of the falling output, it is hoped that the new discoveries made during the year, together with judicious advances for machinery, provision for crushing, and other facilities will cause an improvement before long. At the same time, it is to be feared that, unless capital is more easily obtained to carry properties beyond the prospecting stage, any marked increase in the gold yield is, on present prospects, unlikely. The discoveries at Payne's Find, in the Yalgoo goldfield; at Mt. Egerton, in the Peak Hill goldfield, and Weston's, in the Yilgarn field, all separated from each other by considerable distances, are encouraging and promise to come up to expectations. The severe drought has retarded operations generally. Another factor to the falling output is the general reduction in the grade of ore as greater depth is attained. The Government continues to render assistance to bona fide prospectors by loans of equipment and means of transport. That the prospector is not idle is shown by the fact of 10,028 acres being held as prospecting area for gold and minerals. The area held under mining lease for all minerals is 65,258 acres, a decrease of 843 acres against 1910. For prospecting coal and oil, 38,500 acres is held, a reduction of 11,789 acres. There was a decrease of 857 men employed in gold mines, and 264 at copper and coal mines.

During the year, 2,735,943 tons of gold ore was treated at all mines, a decrease of 148,355 tons. The East Coolgardie (Kalgoorlie) field showed an increase of 90,453 tons. On this field 5836 men are engaged at all work, and the production of \$16,050,130 was recovered from 1,726,998 tons. The output is lower, but generally the field is encouraging. On the East Murchison field three mines closed down and two others reduced their output. Large decreases were reported from the Broad Arrow, North Coolgardie, Mt. Margaret, Murchison, and Coolgardie fields. In the Black Range district, the Yuanmi mine should add considerably to the output; while in the Murchison, the Cue district shows an improvement. The Day Dawn district is quiet and the Great Fingall's output decreases. Around Coolgardie there are promising developments. The prospecting which followed on the Bullfinch discovery has resulted in opening of fair prospects in outlying centres. A plant is being erected at the Bullfinch and should soon be working. At the close of the year there were 33 state mills at work, and from the inception of this system 843,780 tons of gold ore was treated, with a yield of \$18,600,000; and 51,553 tons of tin ore produced tin worth \$343,000. During the term under review only 59,373 tons was handled, yielding \$1,161,654 in gold. There was a loss on working the mills of \$37,400; \$1,450,000 has been spent to date on all plants, and the total loss is \$144,000. The Geological Survey department consists of 19 officers, who have been busy throughout the state at varied problems. Assistance to small mines, under the Mining Development Act, totaled \$42,500. The Water Supply branch sunk 14 shafts, 993 ft. in all; hand-drilled 169 holes, 11,622 ft.; and diamond-drilled 6 holes, aggregating 1907 ft. Tanks and reservoirs were enlarged, improved, and roofed at several points.

The production of all minerals during 1911 was:

Gold, value .....	\$29,115,000
Coal, tons .....	249,980
Copper ore exported, 22,676 tons, worth.....	\$390,500
Tin ore exported, 560 tons, worth.....	\$303,500
Lead ore exported, 1549 tons, worth.....	\$75,000
Pyrite mined, 9739 tons, worth.....	\$17,600
Wolfram mined, 194 tons, worth.....	\$4,350
Silver recovered at mines, worth.....	\$91,500

## Mt. Morgan Gold Mining Co., Ltd.

Attention has of late been directed to the operation of this great gold and copper mine, on account of its gold and copper output, shortage of power, change of smelting practice, change in management, and low profits made. The power shortage has been remedied by the addition of four new blowers, and now four blast-furnaces can be kept going. Ores from this mine were formerly roasted and treated by chlorination, the copper being smelted, the necessary limestone and ironstone fluxes being obtained from Marmor and Ironstone island, in Queensland. From precipitation of mine-water, a fair amount of copper has always been won. When the Many Peaks pyrite orebodies, containing up to 2.25% copper and some gold, were opened, and the mine connected by rail with Mt. Morgan, it was decided to start pyrite smelting. Trouble was experienced, and experts from Mt. Lyell were called in to help. The present position is that the whole concern is being investigated. The local press in Australia has criticized the company for indifferent bookkeeping and high cost, but it is fair to remember that those in charge have had many unforeseen

## Mining in the Transvaal in 1911

The annual report of the Transvaal Chamber of Mines is a voluminous affair of 509 pages, which goes into every detail connected with the mining industry, which produced \$190,530,000 in gold, diamonds, coal, tin, and copper during 1911. An analysis of the gold production of this state of the South African Union shows the following:

Ore hoisted and taken from surface dumps (short tons) .....	27,389,872
Percentage of waste sorted on surface.....	13.01
Tons milled .....	24,456,821
Average number of stamps at work.....	10,020
Average number of tube-mills at work.....	223
Duty per stamp per 24 hours, tons.....	7.76
Gold yield from amalgamation .....	\$107,780,000
Gold yield from cyanidation .....	\$67,175,000
Total value of yield .....	\$174,955,000
Value of ore per ton milled.....	\$6.74
Working costs per ton milled.....	\$4.34
Working profit per ton milled.....	\$2.40
Total profit .....	\$58,625,000

MT. MORGAN IN 1889. THE WHITE CROSS MARKS THE TOP OF THE MOUND.

difficulties to combat. The annual report of the company for the year ended May 31, 1912, gives the following particulars:

Ore treated (oxidized, silicious sulphide, auriferous copper, and Many Peaks), tons.....	351,858
Limestone flux used, tons .....	64,066
Ironstone flux used, tons .....	367
Waste rock removed from open-cut, tons.....	222,446
Waste rock removed from underground, tons...	8,752
Total gold yield, ounces .....	134,575
Total copper yield, tons .....	7,440
Auriferous copper ore content:	
Gold, dwt. ....	9.93
Copper, per cent .....	2.71
Total revenue .....	\$ 4,945,000
Total expenditure .....	3,656,000
Gross profit .....	1,289,000
Dividends paid .....	1,000,000
Depreciation .....	245,000
Reserve funds, total .....	1,030,000
Ore reserves (copper, 3.5%; gold, \$10), tons..	1,499,000
Ore reserves, total (copper, 2.5%; gold \$5 per ton), tons .....	2,027,000
Total revenue to date .....	\$89,820,000
Total dividends to date .....	\$39,395,000

Total gold output of Transvaal since 1884...	\$1,625,635,000
Total dividends paid since 1887.....	\$415,855,000
Labor employed, white, average.....	25,655
Labor employed, colored .....	201,075

In addition to the above data from gold mining, the report gives the diamond output at 1,843,341 carats, valued at about \$8,140,000, which mostly came from the Premier mine; 4,343,680 tons of coal; tin ore valued at \$2,070,000; and copper ore at \$258,000.

The various committees of the Chamber of Mines have dealt with what appears to be a vast amount of work in regard to native labor; miners' phthisis; the Mines and Works Act No. 12, of 1911, especially with reference to the non-working of plants on Sundays; Mining Taxation Act, 1910; Stamp Duties and Fees Act; Companies Act of 1909; Irrigation Act; Local Government Ordinance; Commerce and Industries Commission; Financial Relations Commission; patents, explosives; Workmen's Compensation Act; Water Supply. About 190 pages of the report are taken up with statistics of gold production, coal and diamonds, dividends paid; labor employed and mortality data; and amounts of stores purchased on mines. Native labor seems to be an important feature on the Rand, and much space is given to the subject from recruiting natives to the mortality statistics.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Tonopah-Belmont Mine

The Editor:

Sir—In your issue of August 3, on page 158, an item appears listing the equipment in the new Tonopah-Belmont mill. This list refers to 12 Deister tables. This is an error and the item should read 12 Wilfley tables.

O. H. JOHNSON.

Salt Lake City, August 12.

### Railroad Mineral Lands

The Editor:

Sir—The article in your issue of July 27 about railroad mineral lands seems to me to be a topic well worthy of fuller investigation and enlightenment.

In northern California particularly, there has been much confusion and dissatisfaction with the conditions entailed by the grant to the California & Oregon Railroad Co. and its successors, the Central Pacific and the Southern Pacific companies. This grant of land was made to the railroad company by an act of Congress in July 1866, "to aid in the construction of said railroad." This grant gave every other section of land in a strip twenty miles wide through the northern end of the state. Surveys made in 1866, 1868, and 1870 quite freely marked the mineral lands as exhausted, worked out, or abandoned. Later, owing to the development of quartz mining and new discoveries, there was much dissatisfaction over the grant to the railroad.

For many years miners had free access to the railroad grant, and by them it was generally understood that 'mineral land,' meaning in this region land with gold mines and gold-bearing veins, was exempt, or would be exempted from the grant. At a later time, it was claimed that the railroad had not completed its line northward from Red Bluff, or Redding, within the time prescribed under the terms of the grant, and that it would be forfeited back to the government. In some manner this fault was adjusted in favor of the railroad's holding the lands. Again there was complaint and uncertainty among the prospectors, miners, and locators, but they continued to work upon the grant as upon vacant government or public lands.

Within the last eight or ten years the Central Pacific Co. has been active in obtaining final patents to all lands within the grant; even listing and obtaining patents to small subdivisions and fractions of quarter-sections scattered about and connecting with the best mineral-bearing and gold-producing locations. Prospectors and miners were again alarmed, some meetings were held, and indignation expressed. The miners were next soothed into inaction and indifference by a general belief or understanding that, under the terms of the grant, the railroad company was obliged to sell the land at a maximum price of \$2.50 per acre when it perfected title to the lands. It was generally thought that this afforded as good or a better chance for the locators and miners to get title than the government itself offered. This understanding again kept them quiet and more or less indifferent and negligent.

It was the custom of the railroad company to list and advertise in the country papers columns of descriptions of these lands by section, subdivisions, and fractional survey figures, which the average prospector or miner had neither time, knowledge, nor patience to wade through. Over the entire region of mountainous and broken land the survey landmarks, if ever properly set up, had been effaced or destroyed. No one but a person familiar with land surveying, and provided with proper instruments, could determine in many places even the section or town-

ship boundaries. Under these conditions the railroad acquired title in many instances to lands where mining was in actual progress, to land located and recorded on local district records, and over the heads of miners working their claims. In one instance, at least, patent was granted to the railroad company to land with a 10-stamp mill upon it in operation.

Where a locator or miner was aware that the railroad had 'listed' his land, his recourse was to appeal to the local Land Office, which might be a hundred miles distant, take with him at least two witnesses and prove that the land included a gold mine. To the average prospector this was harder than diorite. The consequence was that he often said, "Well, let 'em get it," thinking he could buy it outright for \$2.50 per acre from the railroad company. Now the miner is confronted with the railroad patents to thousands of acres, dispersed and intersecting the best mining ground in the state. He is permitted to prospect upon these lands, but when he applies to purchase any of them he is now informed from the railroad land office that they "are not on the market." In a number of cases known to me, the company's reply to applications was "that their records were destroyed by fire" and the land had to be resurveyed, platted, graded, or whatnot. In other cases: "when the land is on the market you will be advised." Furthermore, there seems to be no limitations as to the price to be asked when it is offered.

Another phase of the situation is that the railroad company, while refusing to sell these grant lands, leases them by the year or longer to stock-raisers. The company rents whole sections of 640 acres, or a number of sections, at \$50 or what it can get, per year. This arrangement helps the company and gives the stockmen a splendid opportunity to rent the railroad land and get most of the grazing on private holdings and public government land for nothing. Properly, when the railroad rents grazing land, it should build its share of fencing. It is not apparent that it is concerned on this point.

The effect the present conditions have upon mining and development of mining property is becoming more and more apparent and discouraging. Capital is slow enough, for various other reasons, to invest in undeveloped gold properties. No man or company of men is anxious to operate a claim or a property where the pay-vein may strike or dip into adjoining ground owned by a powerful corporation that will neither buy, sell, fix a price, nor join in developing the mine. The railroad company may see fit at some time in future to raise its blockade for its own interests. Probably, however, its charter will not permit of its ever becoming a charitable institution. A dog in the manger that neither eats hay nor permits the ox to do so is usually persuaded with a club. In other cases our government, by the people, usually compromises by giving the dog the hay.

PROSPECTOR.

Shasta, California, August 10.

[The situation regarding these disputed lands is a difficult one for all concerned. Naturally the railway people try to get all that any construction of the grant will allow them. Naturally also, they refuse to sell while the title they can give is in doubt. In the meantime development is stopped. The matter should be settled by the courts, and settled promptly. We are glad to understand that a test case is being arranged.—EDITOR.]

COPPER production increased in Nevada from 64,359,398 lb., valued at \$8,173,643, in 1910, to 67,377,518 lb., valued at \$8,422,190, in 1911, according to the U. S. Geological Survey. The increase was practically due to the mines at Ely, in the Robinson district, White Pine county, which yielded 67,033,547 lb., or 99.49% of the entire state production.

THE Witwatersrand Native Labor Association, Ltd., annual report shows that its expenditure on recruiting natives was \$1,360,000.

## Special Correspondence

### NEW YORK

RYAN ON COPPER.—RAY AND CHINO.—SHANNON PAYS DIVIDEND.—COPPER IN STEEL RAILS.—PORCUPINE.—SILVER PRICES.

New York is manfully endeavoring to see a marked revival in business. The crop outlook is expected to redeem the situation and clear the air of all doubts and perils. All lines are counting their share in the country's agricultural prosperity. John D. Ryan returned from a two-months European trip this week, and is evidently much of a bull on the copper-metal market, expressing the wish for a much greater increase in copper output. Mr. Ryan, when interviewed, said in part: "Uses of copper metal in European countries through which I traveled, including France, Italy, Austria, Germany, and England, are increasing, and the demand for the metal is growing proportionately. Business in England, France, and other European countries is exceedingly good, but Germany is outstripping the world in manufactures of all sorts. Germany's big copper requirements are not only for home consumption, but for export goods also. Her manufactures are going all over the world. Large demands for German products are coming from South America. A material increase in production will be necessary before the supply will equal the demand. As I have already said, I would like to see stocks of copper increase both here and in Europe. I hope refinery statistics from now on will show above 130,000,000 lb. per month."

The growth of operations at the Ray Consolidated is covered by the report just issued for the quarter ended June 30. The monthly output for the first quarter of the year was 2,374,314 lb.; for the quarter ended June 30 was 2,984,024, or practically 3,000,000 lb. per month. The ore handled during the year was all of the same average copper content, 1.72; the percentage recovered during the first quarter was 69.37, a little better than the June quarter, which was 68.85. Costs for the period covered were 8.95c. per pound, and net earnings \$481,944, as compared with \$358,625. Ray is carrying all unsold copper at 12½c. per pound, and actual earnings for the June quarter are some \$100,000 better than the earnings statement shows. During the present quarter, operations will be further enlarged. The July tonnage handled was about 4500 tons per day, and August output is expected to show an average of 500 tons per day. While Ray Consolidated is developing along these lines, undoubtedly to become one of the largest copper mines of the world, the Chino is breaking and making some wonderful records. In July the property had an output of a little more than 3,100,000 lb. of copper, and this was produced at a fraction under 6½c. per pound. This result achieved within two years from the commencement of development, is beyond question a record in the development of copper property. It is true that the high grade of the ore in which the Chino is working, and the handling thereof by steam-shovels, are jointly responsible for the result. Chino is expected to produce 70,000,000 lb. of copper per year, and to get costs down to 6c. per pound. When this is achieved, Nevada Consolidated will have to yield its place as the cheapest big copper producer of the United States.

The week saw another copper mine return to the dividend list—the Shannon. The Shannon has always been something of a market favorite in Boston. Previous dividends were 50c. per share in 1906, and \$1 in 1907. The present disbursement, therefore, will be the first the shareholders have received in five years.

There is said to be a deal pending to sell the Shattuck-Arizona to a group of French brokers. The shaping of the deal covering the group of claims adjoining the Butte & Superior is proceeding rapidly. The flotation is to be made by Hayden, Stone & Co., and the shares are to be offered in the first instance to Butte & Superior shareholders. D. C. Jackling is expected to come East in a few days to close

final details in reference to this property, and the Alaska Gold Mines Co. as well.

A most interesting incident has just been brought to light by the engineers of the New York, New Haven & Hartford railway. In checking over the records of rails in actual use there was noted to be some six miles of track whose rails, still in good condition, were laid long prior to any other rails still in use; further examination disclosed the fact that the rails in question had been imported from Glasgow, Scotland, and a chemical analysis showed that they contained 1¼% of copper. Already orders are being placed for rails to contain 1½% of copper, and if its use prolongs the life of the steel rail, and prevents breakage, the fact will be a doubly important one. With the greatly increased traffic and furious speed of the present day, defective rails have become one of the chief problems of the railway companies. If the use of copper will give longer wear and a tougher rail, it may be confidently expected that it will hereafter go into every rail rolled by the steel companies, and copper producers will have found an outlet for an additional hundred million pounds of copper per annum.

The present reports from Porcupine are in marked contrast to the vast promises current a little more than a year ago, when properties were spoken of as 'proved' and snapshots of trenches or head-frames were exhibited in proof thereof. The Rea Consolidated Mines, the property in which the Consolidated Gold Fields of South Africa was at one time supposed to have become heavily interested, reports a depleted treasury, and acknowledges the immediate necessity for further financing. A sharp advance and a much firmer tone is noted in the silver market, owing to cabled advices that the Indian treasury has entered the market, and is at length buying for rupee coinage. Quotations are 61¼c. per ounce in New York and 28¾d. per ounce in London, the highest figures registered since 1900, when the announcement was made that the Indian Government would no longer buy silver.

### JOPLIN, MISSOURI

ZINC ORE REACHES RECORD PRICE OF \$66 PER TON.—MINING OLD YELLOW DOG PROPERTY WITH AID OF BOATS.—GASOLINE LOCOMOTIVE FACILITATES WORK OF AMERICAN ZINC, LEAD & SMELTING COMPANY.

Since the Joplin correspondence appeared in the *Mining and Scientific Press*, July 27, telling of the record prices of zinc ore which at that time had gone to \$60.50, a basis of 60% metallic zinc, the market became stronger, going to \$64, basis, while choice lots running high in metallic zinc brought as high as \$67. The year is thus featured by unusually strong offerings for zinc ore, the nearest approach to these prices having been in 1905 when the market went to \$57, basis, with choice lots bringing \$60. At the time of writing, however, the market has subsided, and the close of August sees a strong demand at lower prices, the range being from \$52 to \$57 per ton, basis, the same as the previous record of 1905. The present price is about \$15 per ton higher than for the corresponding week of 1911, although there is little apparent increase in the production of concentrate. The newly developed mines have been able to replace the old producers that have gone out of existence, and that is about all. A year ago the district was turning out about 5000 tons of blende per week, and today, although numerous mines are working double and even treble shift, the output is not much in excess of this figure. Extensive drilling hints of a possible increase from the development of newly discovered ore reserves, but this increase cannot be expected to materialize in much less than a year, and in the meantime some of the present-day big producers may be worked out. At best it looks as though the district may be able to increase its output very slowly, with the chances that 6000 tons per week will be the maximum, even if the present high scale of prices continues. Statistics from the United States Geological Survey show an increase of about 9% in the production and the consumption of spelter over

the past six months of 1911. Zinc exports have increased 60%; ore exports have increased 55%. A strong demand for zinc is responsible for the great activity, and operators in this district believe they will never see a return to the low prices that prevailed up to this year.

Heavy pumping costs at the Yellow Dog mine, once the banner producer of the district, have been avoided through the use of a flat boat in the flooded drifts of the once famous producer. The mine was worked in sheet-ground, pillars being left every 30 or 40 ft. Some of these were drawn by the former operators, but the ground was in no wise endangered and many pillars, rich in ore, were left standing. After the stope had been taken up the drifts were 20 to 25 ft. high. In these old workings the water now stands 15 ft. deep. From the main shaft to the most remote heading the distance is between 300 and 400 ft. A great area had been cut in every direction, and the cost of draining this big underground lake would have been far in excess of any returns that could have been expected from the mining of the rich pillars that yet remained. Instead of draining the ground, a sub-leasing company launched a barge. In mining the pillars they stretch a tarpaulin between the boat and the ore to prevent much of it falling into the water. When the barge is filled it is paddled to the bottom of the shaft, the ore is loaded into cans, is hoisted, and is then milled, the recovery being between 4 and 5% zincblende.

Mules have been replaced with a gasoline locomotive, the

the latest move of any importance being the opening of 5% sheet-ground in the United-Lehigh mine at Carl Junction. Here a big opening is being cut in virgin ground. The mill at this property has a capacity of 300 tons per shift and formerly operated on a sheet-ground lease at Duenweg by the same company.

Hand jigging is commonly used in cleaning calamine, but the high price has encouraged more substantial work. C. C. Player is completing a small mill at Spring City. The ore is thin and needs more treatment, but a big area is to be worked. Where hand cobbing is possible the dirt is not even hand jigged. Granby continues to be the heaviest producer of calamine. The price now ranges from \$28 to \$30 per ton, assay basis of 40% metallic zinc, with choice lots bringing \$38. A 250-ton mill has just started on the O. D. Bittick land at Spring City, this being the largest concentrating plant in that camp. It is of sheet metal. Ore is found at a depth of 170 ft. The Onondaga Mining Co. recently purchased the fee on which the mill and mine are situated.

### BOSTON

SHANNON DIVIDEND.—MAYFLOWER.—GRANBY.—CHEMUNG SOLD.—COPPER PRODUCERS ASSOCIATION.

There were two or three strings tied to the action of the Shannon directors, a few days ago, in declaring a dividend of 50c. per share. The dividend is not payable until October 1. It is not stated whether it is to be a quarterly one or not. The directors made no commitments except the declaration of the single dividend. It is known that the Hayden, Stone & Co. interests on the board wanted a dividend declared as a concession to higher-priced copper and the pressure for increasing dividends all along the line. On the other hand, the Paine, Webber & Co. faction advocated going slow. The action represents a compromise. Shannon is earning \$1,000,000 per year, or over \$3 per share. Therefore, it is believed that a dividend of 50c. quarterly can be sustained. Shannon is in excellent financial shape and has so far distributed but a very small portion of its earnings in dividends to stockholders.

LEAD AND ZINC DISTRICTS OF MISSOURI.

first of the kind in the district in steady use, in the underground workings of the American Zinc, Lead & Smelting Co., at Prosperity. The distance between the Sharpsburg mine and the American-Davy mine, the course of travel of the new locomotive, is 650 ft. The locomotive will pull a string of eight to ten cars. The weight of the engine is six tons, including the trucks.

Suit brought against former directors of the United Zinc Companies in Massachusetts, alleging fraudulent sale of lands to the Companies, and involving a sum between half a million and \$600,000, will in no manner effect the Companies' activities in this district. The alleged fraud centres on the sale of 75 acres in the Aurora camp, which the directors, through the general manager, Royal B. Young, of Boston, claim was not worth the purchase price. This tract has never been a good producer. United Zinc is operating several mines in and near the Joplin camp,

In the Lake country, Mayflower No. 20 and Old Colony No. 16 drills have both penetrated the Mayflower lode. The two drills are working within a few hundred feet of each other. St. Mary's Mineral Land people have not heretofore been successful in actual mine management, but Mayflower will probably turn their luck. As Old Colony is now stated to represent a uniform extension of Mayflower conditions, and as it has been selling a few points below Mayflower, there has been some disposition to give it preference in the buying. Outside of some faulting in the lode, the expectations of the management have been realized in finding it at theoretical points.

D. C. Jackling is expected in Boston in a few days to consummate the details of the Butte & Superior deal, as well as that of the Alaska Gold Mines Co., which Hayden, Stone & Co. are financing. A number of alterations and additions are being made at the Butte & Superior con-

centrator to promote efficiency. The plant will eventually be increased to 2000 tons per day. The market recovery of Granby is gratifying to Boston, which has always had a strong stake in the property. Granby is selling now around 55, about half of its high price of two years ago. It is learned here that the diamond-drill developments in Granby's Hidden Creek property are exceeding expectations and that the management has decided on building a 2000 instead of a 1000-ton smelter. It is a great satisfaction to see the old familiar mines either holding their own or coming back.

Phelps, Dodge & Co. are again in the field buying new properties. It is now practically conceded that Chemung, a Grant county, New Mexico, property, is to be taken over by the firm. Chemung is a property of 953 acres. The company was formed as a reorganization of the Tyrone Development Co. at the tail end of the copper boom in 1907. The organizers and holders of the bulk of the stock were United States Steel Corporation people. The company was incorporated under Minnesota laws, with a capitalization of 300,000 shares, \$10 par, \$9 paid in. Of this number, 200,000 shares were listed in the qualified department of the Boston Curb. The stock was also traded in on the Duluth board. The company probably has today less than 100 stockholders. It has good management and ample financing, but the property was shut down on account of the low price of copper. Phelps, Dodge & Co. own the adjoining Burro Mountain property and will be in position to make Chemung a considerable producer, as it has a large tonnage of concentrating ore on hand. The Phelps, Dodge & Co. bid for control was around \$6 per share. The faithfulness with which the Copper Producers Association furnishes the statistics of copper production and deliveries is causing much favorable comment in Boston and is strengthening confidence in the copper situation. The July increase of approximately 6,000,000 lb. in the copper surplus was not an unmixed evil from the producers' standpoint, as it came at a time which served to emphasize even more than ever the impartial character of Copper Producers' statistics. Accurate and responsible publicity is accomplishing wonders for the copper situation at this time.

### LONDON

#### WHEAL KITTY.—SOUTH AMERICAN COPPER COMPANY.

The doings at the Wheal Kitty tin mine in Cornwall are always of interest, although the mine is a small one, and the tonnage treated may seem paltry when compared to the big mines of the world. The mine, as a matter of fact, affords an excellent example of economical working and provides an effective contrast to some of the extravagant methods not unknown in the City of London and in Cornwall. In writing six months ago of the results at this mine I had to record with regret that the content of the ore mined had seriously fallen, the yield for the second half of 1911 having been 19.9 lb. black tin per ton, as compared with 28.1 lb. during the first half, and 35.2 lb. during the period from the commencement of work by the present company under the auspices of J. H. Collins to the end of 1910. The report for the first half of 1912 shows a substantial improvement in the yield, the figure being 28.5 lb. black tin per ton. The mine suffered inconvenience from the coal strike, as operations had to be entirely suspended for five weeks. This fact and also closer sorting underground caused the total amount of ore raised to be less than usual, 6090 tons, as compared with 8384 tons the previous half-year. The tin concentrate sold was 77 tons, realizing £9448. The net profit was £702, which added to the balance carried forward from the previous half-year made a disposal balance of £1522. Out of this, £375 has been written off for depreciation, and £298 has been paid as dividend on the preference shares at the rate of 10% per annum. The total cost was 28s. 8d. per ton. Sara's shaft is now down 750 ft. and a lode cut at 720 ft. is being developed. This is supposed to be in the faulted portion of

the main Kitty lode which was the objective in sinking the shaft. The cross-cut at the 540-ft. level connecting Sara's with the Wheal Vottle workings is nearly complete.

In April last I sent some particulars of the South American Copper Co., which was formed in 1907 for the purpose of reopening the Aroa group of copper mines in Venezuela. These mines have been known for 300 years, and from 1882 to 1894 they were worked by the Quebrada company, an English venture. In the latter year the workings collapsed and the property was abandoned. During the year ended June 30, the ore extracted and shipped to Europe realized £75,447 gross. The cost of mining, freight, smelter charges, etc., was £47,803, leaving a profit of £27,644. Out of this, £2595 was paid as London expenses and income tax, and £2510 as directors' extra remuneration. Dividends amounting in all to £22,358 have been paid, which is 250% on the paid up capital of £9983. The nominal capital of the company is £15,000, divided into 150,000 shares at 2s. each. Of these, 75,000 formed the original issue at par, and the other 75,000 have been issued at £1 each. So far £20,170 has been paid up on the latter. These shares have been subscribed in France, and the money obtained will be available for the expansion of mining and concentration operations. W. A. Heywood has gone to the mines to report on the metallurgical problem.

### BUTTE, MONTANA

#### AUGUST PRODUCTION SHORT.—GUGGENHEIMS IN BUTTE.

August copper production by the Anaconda smelter, which includes the output of all the Anaconda mines, the Tuolumne, North Butte, and some other custom ore, will not exceed 25,000,000 lb. The East Butte will add slightly more than 1,000,000 lb. to the total. The outputs of both the Anaconda and East Butte smelters are less than two and three months ago, but it is asserted that the falling off is due to natural and ordinary causes. The decrease in the Anaconda production is claimed to be due to extra development being done at some of the mines and to the fact that a portion of the concentrator at the Washoe smelter is being reconstructed. The Pennsylvania mine, one of the largest producers of the Anaconda company, is closed to permit the substitution of compressed air for steam. At the same time the shaft of the Pennsylvania is being sunk 400 ft. deeper. Sinking is also being done on the Berkeley, and extraordinary development is under way at the West Gray Rock, Silver Bow, Anaconda, Mountain View, and Tramway. The Mountain View, which was partly shut down for two weeks while repairs to one of the engines were being made, has resumed operations. Work on the 1600 and 2000-ft. levels was stopped during the shut-down. A large station has been cut at the 2000-ft. level, and a cross-cut started north. Some driving has also been done on that level. A 35-ft. sump has been cut below the 2000-ft. station and a Knowles sinking pump is caring for the water, which amounts to about 15 to 20 gal. per minute. A similar pump has been placed in the shaft at the 1900-ft. level. At the Tramway, both the main and auxiliary hoists have been remodeled to use air.

There is no longer any doubt that the Guggenheims are getting a good mining hold in the Butte district, which was generally supposed to belong almost exclusively to the Amalgamated Copper Co. It is no longer denied that the Guggenheims are in control of Butte & Superior, the big zinc property, and it is now stated officially that D. C. Jackling is the real manager, A. B. Wolvin having practically retired from the position as managing head of the company. John M. Hayes, who, with Mr. Jackling, represents the Guggenheims in the Utah Copper Co., is spending a great deal of time in Butte, and he has purchased or taken under option a score or more mining properties, mostly undeveloped ground, for the Guggenheim interests. G. O. Bradley and F. G. Janney, of the concentrating department of the Utah Copper Co. in Utah, have been inspecting the new mill of the Butte & Superior and have directed certain changes for the improvement of the mill.

Mr. Bradley expresses himself well satisfied with the working of the mill and the percentage of recovery, although the average has been considerably less than generally reported. The financial men interested in Butte & Superior have protested against the policy of misrepresentation and exaggeration which has been followed by someone regarding Butte & Superior operations and earnings, and lately there has been much less of it. As one of the men interested in the company said: "The truth is good enough, and exaggeration hurts." The entire concentrating plant is now completed, but only the first unit, having a capacity of 500 tons per day, is being used. The whole plant will not be put into operation until the new hoist is in operation. That will probably be some time early in October. The mill is designed to treat 1000 tons per day, but it is estimated that it will be able to handle 1200 tons. The Butte & Superior and allied interests own controlling interests in the North Butte Extension Co., the Butte-Milwaukee Co., the Brundy group of claims on the east side of the district, about a dozen claims in the northern portion of the district, and are still negotiating for more ground. Mr. Wolvin also tried to get possession of the Bullwhacker company, which owns a small producing mine on the east side, but made the mistake of offering too much for the stock. Other interests were about to get control of the company on a basis of 10c. per share, when Wolvin offered 25c. The result was that the big holders wouldn't sell at all and are now talking about resuming work on the mine. Patrick Clark, of Spokane, is the chief owner of the Bullwhacker. It was worked six or seven years ago and shipped some ore. A dividend of 1c. per share was paid and the stock soared to \$3 per share. After the dividend had been paid and the public bought liberally of the stock the mine was shut down because it could not be operated at a profit. Mr. Clark said then that the shut-down would only last until he could erect a leaching plant. He has been back in Butte the past week with an engineer, and is talking about putting up a copper leaching plant at once. The stock has become active again and is selling at 27c. The Butte Hill Copper Mining Co. owns about 16 patented claims in the far north section of the Butte district, and the Guggenheim representatives have been negotiating for the property, but Walter Harvey Weed says he has some Duluth people who are anxious to get it, and a wire from him to the officers of the Butte Hill has added interest to the negotiations.

### JOHANNESBURG, TRANSVAAL

FALLING DIVIDENDS.—SHORTAGE OF CAPITAL.—LEGISLATIVE BURDEN.—MINERS' PHTHISIS ACT.

The mining topics attracting most attention here just now are largely connected with the pressing need that undoubtedly exists on the Rand for greater economy in working, or for some other method of meeting the demands likely to be thrown on the mining industry by the Union Parliament during the next few years. The latest figures show that owing to a variety of circumstances, the Witwatersrand gold-mining industry, during the half-year ended June, although distributing in dividends £3,750,000, has failed to reach the corresponding dividends in 1911 by a sum well over £300,000. This state of affairs, following a material dividend decline in the previous year, although accompanied by a marked increase in tonnage milled and actual gold produced, has naturally caused some comment and not a little surprise, that in the face of these facts the Union Legislature at Cape Town should not hesitate to impose additional heavy burdens on gold mining, upon which the general prosperity of South Africa so largely depends. It is worthy of notice in passing that this dividend decline is largely due to market conditions over which those in charge of the mining industry do not appear to be able to exercise any control. As far as the total working profits are concerned, they have, during the past half-year, increased to a much larger extent than the dividends declared have declined, thus making the dividend shortage appear all the more serious. The ex-

planation may be given that the working profits have had to be used to a much larger extent than formerly for what was, strictly speaking, capital expenditure; owing to exhaustion of working capital, or insufficient working capital in the first instance having been provided for most of the new producers which have so largely contributed to the gold output and working profits during the half-year. The bad odor into which the South African mining-share market has fallen prevented any other course being adopted with any prospect of success, and where there were no prospects of producing working profits within a reasonable time, the somewhat serious step of closing down the mines has been adopted, as it was hopeless to attempt to raise additional working capital on satisfactory terms in the share market. There are also instances where the carrying out of the merging policy of mines of doubtful value with occasional dividend-payers has only resulted in increasing the capital without adding to the immediate dividend-earning capacity of the amalgamated concern. Other merged concerns have found it necessary to spend large borrowed sums in capital outlay and extension, thus entailing additional interest and redemption charges on the working profits. There may also be added to these drawbacks those of constant falling grades and increasing working costs. The latter drawback has continued for several years, for where the grade, by manipulation, or selective mining as it is now called, has been improved, the benefits have been neutralized by the resulting higher costs of working. It is clear, therefore, that the actual working profits have only increased as a result of several promising new producers entering the list, such as Modder B, City Deep, and others, whose efforts have added to the working profits without benefiting the dividends. The mismanagement at the East Rand Proprietary Mines has reduced the dividends by £183,442, a loss which even new dividend-payers like Brakpan, Bantjes, and Jupiter mines combined have not been able to make up while, owing to natural exhaustion of many of the outcrop mines and failure of the deep-level mines to neutralize the consequent effects, the dividend list has also had to considerably suffer during the last six months. Little wonder need therefore be expressed that such an additional drain on the dividend capabilities of the mines should have been imposed as that of the Miners' Phthisis Compensation Act which comes into force on August 1 without the Government contributing to the cost, as in other countries. By this act of the legislature, each miner suffering from phthisis, and the relatives of any miner who has died from this disease in the past, will become entitled to claim a maximum amount of £400 from the employers. It has been estimated that one out of every three white miners now working on the Rand is a victim to the disease, and thousands have died from the disease in the past. The new liability now thrown upon the mines is difficult to estimate, but it is possible that during the two years' continuance of the act it may be in the neighborhood of £4,000,000, and it is certain to be over £1,000,000 per year. Toward this amount the Government contributes the paltry sum of £100,000 to relieve the poorer mines which would otherwise probably close down. This act of Parliament is also accompanied by what is termed a 'Miners Phthisis Insurance Fund,' giving much the same benefits, to which the men contribute 2.5% of their wages and the mine-owners 2.5% of the wages paid to the miners for the first two years and 5% thereafter, the Government contributing nothing. It is as impossible to estimate the liability to be thrown on the shoulders of the mines in these days of declining grades and dividends by this Miners' Phthisis Act as it is to estimate the losses the mines have suffered in many ways in the past through the prevalence of the disease. Much more might probably have been done in the past by mine-owners, miners, and Government to keep it under control, but the feeling prevails that where neglect has been common to all three parties concerned, all, as in other countries, should equally contribute to its relief.

## General Mining News

### ALASKA

#### FAIRBANKS

(Special Correspondence.) -- The property of Hudson brothers on Ester creek has been partly sold to C. Wichtman and M. Bigler, who are working on Eva creek placers. A 2-stamp Nissen mill has been ordered, and will be erected this summer. The shaft is down about 100 ft., with good ore showing at the bottom. At one part a cross-cut shows 11 ft. of pay-ore, besides which some high-grade ore has been opened. F. Fay has sold his interest at the head of Chatham creek to W. Burns and T. McIlroy. Jesson brothers have also sold out to the latter. A few days after acquiring the property, the owners broke into rich ore. At present there is two feet of good ore in the face of the drift. A 4-stamp mill, consisting of two 2-stamp batteries, is already at the claim. C. Furstenuau and McCarty have a good deal of ore opened in the Fairbanks creek claim, and have bought a mill of the Little Giant type and a Monarch concentrator. This will be erected as soon as it arrives by the next boat. A 5-stamp mill is about completed at the Newsboy Extension on upper Cleary creek by McGillvray and Fisher. They intend crushing for claims in the vicinity. A joint pumping plant will probably be put on Cleary creek to supply water for both the Newsboy mill and that on the Extension. The Newsboy mill at present is working when water is available. The east 200-ft. stope in this mine should open well, judging by carefully taken samples. L. Golden is general manager. A 2-stamp Nissen mill will be soon erected at the Tolovana mine. The present Huntington mill will be used for regrinding. A shaft is being sunk near the mouth of the main adit, as good ore has been proved in the lower levels. Rich ore has been cut on the Pioneer lode at the Chatham. Enough ore is in sight to pay for a 5-stamp Joshua Hendy mill, so one has been ordered. W. L. Spaulding, on upper Dome creek, has a small 3-stamp mill at work on rich ore, and a five-days run resulted in gold worth \$780. A fair percentage of cobalt has been found in the sulphide ore of J. F. Zimmerman, and a small shipment will probably be made this summer. The 100-ft. level in the Rainbow has opened a good width of pay-ore. A boiler and hoist are being erected. The small rich vein at the Rexall, on Wolf creek, has opened out well, and a 1-stamp Nissen mill has been ordered. There is a good millsite and plenty of water. The reported finding of tin ore in the Hot Springs district has been confirmed by C. F. Robinson, the discoverer. Holes sunk in the lode show it to be from four feet in width. Samples of ore shown seem to be an altered dike rock carrying cassiterite. The prospects so far are low grade, but the size of the placer tin leads the owner of the claim to think that there are rich placers in the lode.

Fairbanks, July 14.

#### IDITAROD

Nine boilers are being built in on Flat creek by the Guggenheim people. There will be 400 hp. developed, which will drive engines and generators for power used on the big dredge which should be soon at work. Prospects are bright for the present season at the Susitna and Cache Creek districts. Bubb and Barenburg, on Dollar creek, have two giants at work and have found some rich gravel on their benches. Their output will be about \$50,000 for the summer. The output of the Innoko-Iditarod region in 1911 is estimated by the U. S. Geological Survey at \$3,000,000, as compared with \$825,000 in 1910. Perhaps \$500,000 went to Seward by dog-train.

### ARIZONA

#### GILA COUNTY

(Special Correspondence.) -- C. C. Tinkler, representing McArthur Brothers, who have a contract with the Inspiration Con. Copper Co. for building a spur from the Arizona Eastern railroad to the millsite and main shafts at the Inspiration camp, is in Globe getting the work started. A camp is being established. Machinery, horses, and supplies are being unloaded at Miami, and work will be started in a few days. McArthur Brothers also have the contract with the railroad company for the construction of the extension of its line from the town of Miami to the Inspiration and the Live Oak. This work will be carried on at the same time. The main west working shaft of the latter is now 300 ft. deep, and the main east shaft about 100 ft. deep. Sinking is progressing at the rate of over 6 ft. per day. The churn-drill at the South Live Oak has been moved to the northern end of the property on the schist area, and hole No. 3 will be started within the next two or three days. P. G. Beckett, formerly assistant super-

TOLOVANA MINE AT MOUTH OF WILLOW, A TRIBUTARY OF CLEARY CREEK, FAIRBANKS DISTRICT, ALASKA.

intendent of the Copper Queen mine at Bisbee, has been appointed general manager of the Old Dominion mine at Globe, and took charge on August 16. He succeeds G. H. Dowell, who has been promoted to the position of assistant general manager for the Copper Queen company. The Superior & Boston is making small shipments from the second and third levels of the Limestone vein, and the sixth level of the Great Eastern vein. Driving has been resumed on the eighth level east on the latter vein, and cross-cutting is in progress on the twelfth level. W. G. Rice, president of the company, is visiting the mine. Development work has not been resumed at the Black Warrior mine, as predicted by the management a month ago. The mine is now idle and there seem to be no definite plans for reopening it.

Globe, August 15.

The properties of Cobre-Verde company, near Globe, were bought last week by the Calumet & Arizona company of Bisbee, the price being \$500,000. The former leases consist of 81 claims, and besides these the latter company has taken options on others around Globe.

#### MARICOPA COUNTY

The Monarch company is now erecting the 50-hp. Fairbanks-Morse engine, and Rumsey pump. The latter has a lifting capacity of 8400 gal. per hour a height of 2000 ft., but will only have to elevate water 1232 ft. from the river to the mine, a distance of seven miles.

#### MOHAVE COUNTY

From de la Fontaine mine, M. A. Burke and associates have a 40-ton car of zinc ore for shipment and will soon have a similar quantity of lead ore to send out. Samples

from each class of ore have given high returns. It is said that a strong company is to take over the Bi-Metal mines near Kingman, and will erect a large plant. The lode is very wide and worth about \$3 per ton, and could be cheaply mined and milled.

#### PINAL COUNTY

The Copper Queen company has completed the purchase of the Giesemann claims, some 30 or 40 miles from Tucson, in the north end of the Catalina mountains. For some time past the company has had a fair number of men prospecting and developing the purchased properties.

#### SANTA CRUZ COUNTY

A lease, involving \$80,000, has been taken on the Chief group of 12 claims in the Patagonia district. These adjoin the World's Fair mine. Several hundred feet of development has been done in the Chief, and high-grade silver ore opened. It is intended to drive a tunnel about 500 ft., which is expected to cut the World's Fair vein at a vertical depth of 300 to 350 feet.

#### YAVAPAI COUNTY

The Kay copper mine, situated on the banks of Agua Fria river, in the southern part of the county, is shipping 1000 tons of ore to the Swansea smelter. The Tip Top concentrating plant will soon be at work. Driving has been continued in the Fortune mine adit and is now in 412 ft., with 20 to 36 in. of pay-ore opened the length of the work.

### CALIFORNIA

#### NEVADA COUNTY

The Pennsylvania company is pushing on the excavations for its 75-ton cyanide plant, which should be working in about two months. The plant will be similar to that at the Empire mill. There will be about 15 vats and one large Oliver continuous filter.

The shaft of the R. G. Gillespie mine, at Indian Flat, has been cleared of water, and sinking will be continued several hundred feet, and the vein prospected. Delay has been occasioned by shortage of water for power, but electric power has been installed for pumping and the air-compressor, water-power being used for hoisting.

#### SIERRA COUNTY

A fair quantity of ore has been opened at the Willoughby mine, above Gold Valley, and it is intended to start the mill early in September. At the Sierra Buttes the upper mill is crushing ore from the new shoot opened on three levels in the mine.

#### SISKIYOU COUNTY

(Special Correspondence.)—A company of Portland and Yreka people is being organized to develop a coal deposit north of Montague. Tests of the material are said to have shown it to be of a good quality. W. W. Narham and B. K. Collier, of Yreka, are among those interested. Thrash & Coalson are mining rich quartz from their claims on the Forks of Humbug. A lease has been taken on the McCook mill and crushing is about to start. James Ironside has intersected a 4-ft. vein of free-gold ore on one of his claims in the Cherry Creek district. San Francisco people have taken over the Cherry Hill mine and have a small crew at work. Work has been resumed at the Drummer Boy, after an idleness of several years. At the Gum Boot, near Scotts Bar, a full force is engaged and good ore is being opened. San Francisco interests have taken a bond on the Mount Vernon and have arranged for immediate development. C. H. Bryant has bonded the old Elk Creek quartz property and has commenced driving an adit. Good ore has been found in the old workings, but considerable driving will be necessary before the deposits can be cut at depth. Bruce Aldrich and Paris Mathewson report the finding of a strong vein near Sucker creek, supposed to be the Hegler, which was lost several years ago. When first found the shoot was 14 in. wide, and has since widened to over 25 in. The adit has exposed about 60 ft. of the vein and is progressing steadily. The

ore is said to average \$40 per ton. Representatives of San Francisco capitalists have been recently inspecting quartz and placer claims in this neighborhood, and several deals are reported pending.

Yreka, August 17.

### COLORADO

#### CLEAR CREEK COUNTY

Nelson and associates, who have been working a lease at the Bellevue-Hudson property near Lawson, have shipped a carload of galena, rich in silver. The lode worked is from 10 to 24 in. wide, of good smelting ore. Drilling is being continued at the Capital claim on Griffith mountain. By the middle of September the hole should be through to the Capital workings. The Mineral Chief mill is producing about five tons of 72% lead concentrate per shift. The zinc product averages 35%. Hummer & Herber, lessees at the Capital mine, are making regular shipments to the local sampler, which yield highly profitable returns.

#### GILPIN COUNTY

An average of 120 tons of ore per day is being produced by the Frontenac mine, and about 65 tons from the Adudell. Recently the 600-ft. level of the latter was timbered and connected with the 900-ft. depth of the former. Generally these two properties are opening fairly well. From the 600-ft. east level of the Chase mine, 17 tons of ore averaging 2½ oz. gold was shipped. The shaft will be sunk another 100 ft. T. Hughes and associates have shipped 4 tons of \$40 ore from Trail, in Russell district, and the Galena mine, on Central hill, has shipped 6 tons for \$35 per ton.

#### GUNNISON COUNTY

The new compressor of the Elk Mountain Tunnel Co. was started last week and is working well. It is driven by a Pelton wheel, worked under a 500-ft. head. The tunnel now in 1200 ft. should cut the many veins of Queen basin, about 1000 ft. below their apex in the basin. The district is suitable for cheap mining operations, as there is plenty of timber and water-power. A siding is to be constructed to the Elk mountain coal mine. Coal will be brought down from the mine by means of an aerial tramway 4200 ft. long, which has a capacity of 500 tons per day. There will be 100 men employed at the mine, when the plant is complete. The company will spend \$30,000 on general improvements, and should be in full working early next year.

#### OURAY COUNTY

The Mountain Top company is to start its adit at the west side of Virginus basin, at an elevation of about 12,000 ft., where there is little danger of snowslides. The adit, 7½ by 6 ft., will be driven 2000 ft., and should cut the Smuggler-Union-Humboldt-Sweepstakes vein at a depth of nearly 600 ft. below the lowest workings on the Sweepstakes. Twenty-five men are to be put at this work. E. Krisher is mine superintendent.

#### TELLER COUNTY (CRIPPLE CREEK)

Treatment at the Gaylord mill is said to be satisfactory, and 60 tons per day is being handled. Three mills, Portland, Gaylord, and Kavanagh, are now dumping their residue into Eclipse gulch. At Stratton's Independence about 200 tons per day is now being treated from the ore-house. Forty sets of lessees are working at the mine. It is not expected that the Colburn mill will be finished before October.

Two men were killed on the 400-ft. level at the Gold Sovereign mine on August 12, through the mysterious explosion of 40 sticks of giant powder. The theory of the mine inspector is that the accident was probably caused by the striking of crystallized powder with the candlestick. The explosion of one stick set the rest of the dynamite off. The usual method locally is to make an incision in the stick of powder with a candlestick, and then put a cap in the hole made. The verdict of the coroner's inquest was that there was no explanation of the cause of the accident. The Portland mine was inspected last week by the directors, who announce that further improvements

are to be made to the mill. About 500 tons per day is now being treated. The main shaft has reached 1620-ft. depth, and a station is being cut out for the 1600-ft. level. The water-level was encountered at 1610 ft., but sinking the extra 10 ft. was not hindered by water. To date the Miners' Protective Association has issued 3442 cards to men employed at the camp.

The Elkton company is now down 175 ft. with the Raven and Beacon shaft. On the eleventh level of the main Elkton lode the shoot is said to be 900 ft. long and averages 6 ft. wide of a good value. Seven sets of sub-lessees are working at the second, third, seventh, and twelfth levels of the Last Dollar. About 15 cars of ore per month can be shipped.

## IDAHO

### COEUR D'ALENE

Fire destroyed the boiler house, laundry, and dry room at the Snowstorm mine on August 12. The damage is about \$10,000, and is covered by insurance. The boarding-house, worth \$65,000, was in great danger for a time. Spokane men have inspected the Standard property in Revenue gulch. The Ajax tunnel is in nearly a half mile, and it is said that a vein was cut last week, containing quartz and galena. The Success mine, five miles north of Wallace, on Nine Mile, recently paid \$45,000 in dividends, making \$90,000 for the current year. The main working tunnel is now 1000 ft. long, and large orebodies are being stoped above it. Sinking is under way from this level, and a drift 150 ft. long has been driven at 160-ft. depth. High-grade ore containing zinc and lead is being mined. The mill has a daily capacity of 225 tons, and machinery for zinc recovery has been fitted up. About 50 tons of concentrate is produced daily, and 90 men are employed in all.

## MINNESOTA

A new record in Lake Superior iron ore shipments was made in July, when the total was 7,600,233 gross tons, against 5,221,373 tons in July 1911. To August 1 the total this year was 21,290,904 tons, which is also a record at that

STEAM-SHOVEL STRIPPING OVERBURDEN AT THE OLIVER IRON MINES.

point in the season. The shipments by ports last month and to August 1, with corresponding figures for 1911, are given below, in gross tons:

Port.	July, 1912.	To Aug. 1, 1911.	To Aug. 1, 1912.
Escanaba .....	836,346	1,711,806	2,478,294
Marquette .....	511,924	843,177	1,430,814
Ashland .....	771,057	1,102,263	2,103,858
Superior .....	2,324,324	4,698,855	6,668,655
Duluth .....	1,540,324	3,158,450	4,385,802
Two Harbors ...	1,616,258	2,549,740	4,223,481
Total .....	7,600,233	14,064,291	21,290,904

These great shipments have been made possible largely through the wide adoption of steam-shovels.

## MONTANA

### CASCADE COUNTY

(Special Correspondence.)—After pumping for three

months, the Florence mine at Neihart is now clear of water, and a crew of men is cleaning out the drifts and laying tracks. The levels are in good order, considering that the mine has been shut down for six years. It is intended to start deepening the shaft, and a new hoist will be soon completed. The Florence is a somewhat famous old mine, being opened in the good old silver days, with adits and no development ahead of ore extraction. Production is said to have totaled \$1,500,000. There are several thousand tons of ore on the dump, worth about 30 oz. silver per ton. The mine was shut down in 1906, because all ore above the adits was worked out, and the money had been paid out in dividends. Formerly the ore was shipped to Tacoma.

Neihart, August 15.

It is officially announced that the Great Falls smelter of the Anaconda company will be entirely rebuilt, and the concentrating plant of the Washoe smelter will be remodeled for the more economical treatment of copper ores. Structural steel has already been ordered for the former plant.

### FERGUS COUNTY

The Barnes-King Development Co. promises to become active again through the acquisition of a valuable gold property in the Kendall district, and adjoining the ground of the Barnes-King company. Engineers of the latter long ago recommended the purchase of the property known as the Santiago, owned by John A. Drake and associates of the North Moccasin Mining Co., but the Barnes-King directors could not make a satisfactory deal. However, when the Santiago mine suffered disastrously from a cave, and financial difficulties involved the company, the holders of \$100,000 in bonds instituted foreclosure proceedings and the property was sold. As soon as the period of redemption had expired a bank in Lewistown took title as trustee for the bondholders and turned the property over to the Barnes-King in confidence and under the assurance that bondholders would get back their money, although the price at which the property has passed to the Barnes-King company, is to be paid in royalties from the ore mined. The price is \$150,000 and the purchaser pays but \$5000 in cash. It would have taken a large sum of money to rehabilitate the North Moccasin mine and recover the workings, but the Barnes-King will be able to mine the property economically through the Barnes-King workings, which extend to the end lines of the Santiago claim. The Santiago orebody is an immense one and gives an average of about \$22 per ton. The ore will be treated in the Barnes-King mill at Kendall. Barnes-King engineers have made optimistic reports on the Santiago group and have expressed confidence in the company's ability to earn \$25,000 to \$50,000 per month net profits. In addition to this important purchase, the Barnes-King company is about to close a deal for the purchase of even a more valuable property than the Santiago, but in another part of the state.

## NEVADA

### CLARK COUNTY

Holmes and Montgomery, lessees at the Quartette, are breaking out four or five tons of ore per day averaging over \$20 per ton. The old Blossom mine, three miles from Searchlight, will soon be worked again, J. P. Young having secured a lease. About \$325,000 was won from the claim years ago.

### ESMERALDA COUNTY

Bullion worth \$80 was found in the possession of a man at Goldfield, and it is stated that the Consolidated officials have evidence that a number of employees have been involved in a conspiracy to steal bullion from the refinery. At the Silver Pick Consolidated the drift at the 260-ft. level is being extended from the main shaft toward the Mohawk, and the ground of the old Sheets-Ish lease has shown a strong vein which gave several good assays. A new lease is being worked about 800 ft. northwest of the main company workings, where an old shaft has been

repaired and is being deepened. The shaft of the Lone Star mine is down 300 ft., and a station is being cut out. Some rock from the new workings is similar in appearance to the pay-ore of the Mohawk and Clermont, but so far the assays are low in gold. The Goldfield Mining & Ore Reduction Co. has resumed work at the Third Chance claim adjoining the C. O. D. and Atlanta. Two machine drills are at work. The shaft is 380 ft. deep, and a drift is being driven to cut a vein which is known to traverse the ground between the shaft and the C. O. D. Consolidated. The Jumbo Extension is interesting mining men, and its mill is ready to begin testing ore from the Polverde mine. From the 1300-ft. level of the Grizzly Bear mine the Goldfield Consolidated is mining ore carrying gold, silver, and copper, and shipping it to Tooele.

#### HUMBOLDT COUNTY

The National Mines Co. intends to sink a shaft from its No. 5 level to open up below the present workings. This will be done pending the outcome of the present litigation with the Mammoth company. The latter will continue its east cross-cut. The Kennedy-Macdonald mine is making good headway in the shaft workings on the National Mines extension of the high-grade vein. Most of the rich ore in the latter was mined between No. 3 and 5 levels. This would be about 400 to 600 ft. on the dip of the vein. The Kennedy-Macdonald shaft starts at nearly the same level as the Stall shaft, and the vein has a similar dip; it also shows many of the characteristics of the latter. At the Buckskin National, the winze in the south adit is down 70 ft., in ore worth \$50 per ton, over 4 ft. wide. The ore contains iron sulphide, antimony, and a little free gold. A man was arrested last week for stealing about 10 tons of antimony ore from the Bloody Canyon mine. It is alleged that the ore was shipped East and sold.

#### LANDER COUNTY

(Special Correspondence.)—The Maricopa Mines Co. is completing final installation of mill machinery, and expects to commence crushing within a short time. The main adit is in over 2000 ft. and progressing at the rate of 5½ ft. per round. In the stopes three drills are blocking out ore. The adit has penetrated the Chase estate and is expected to soon intersect one of the rich shoots that formerly made the Chase one of the best properties in New York canyon. San Francisco capital is interested. The Jersey Valley mine, near Battle Mountain, is showing favorably under vigorous developments. Work is centred on the completion of a 1200-ft. adit which will tap the ore-bodies at fair depth and give good backs. Daily shipments of ore are being maintained to Battle Mountain and 20 men are employed. It is reported the directors are contemplating erecting machinery. W. F. Pinkham is superintendent. The Glasgow & Western M. & M. Co. is erecting a small mill and cyanide plant on its Copper Canyon properties, near Galena. Development is progressing with a force of 30 men. A good tonnage of ore is said to be available. The Iron Canyon Gold Mining Co. is erecting a small mill at Iron canyon, 12 miles southwest of Battle Mountain. Two shifts are working. The mine has been a consistent producer during recent years. Several small camps in various sections of the county report improving conditions, and in and around Austin the situation is promising.

Austin, August 16.

#### LYON COUNTY

Two stamp-mills and three cyanide plants are kept busy at Silver City. Hamilton and Pollard crushed about 1000 tons of ore at the Nevada Mining, Power & Reduction Co.'s plant, and the McTigue mill crushed over 300 tons during July. The Woodbury and Donovan cyanide works treated 1900 tons of tailing. Quite a number of mines are producing ore. For the week ended August 1 the Thompson smelter received 5323 tons of ore.

The new hoist and compressor plant for the New Yerington Copper Co. has arrived and will be erected at once. The Smith Valley company has opened 3 ft. of ore in its

adit, worth \$60 per ton in gold, silver, and lead. At a distance of 900 ft. to the north another adit has been driven into the hill 120 ft. on another vein, 18 in. wide and up to \$100 per ton. This gives 300 ft. of backs from which to stope. Copper ore has been opened to the east of the latter.

#### NYE COUNTY

Early on Sunday morning, August 18, fire started in the Miners' Exchange Hall, at Tonopah, and seven buildings were destroyed, valued at \$30,000, with only \$1000 insurance. The fireproof wall of the Nye County building stopped further progress of the fire. This is the second fire at Tonopah within six weeks, the first one resulting in \$100,000 damage.

Last week J. E. Spurr and seven officials of the Tonopah & Goldfield railroad visited Manhattan, and inspected the Consolidated, White Caps, and Big Four mines. Three hundred flasks of mercury are produced monthly by the Mercury Mining Co., which is working at Lone, in the northwest corner of the county. C. G. Dennis, the manager, states that the cost of mining and reduction is not over \$5 per ton. The cinnabar is found in a rhyolite. Wood is used in distilling mercury from the ore.

The Kendall-Douglas lease at the Manhattan Consolidated has cut rich ore, and a width of six feet has assayed from \$175 to \$1583 per ton. Work has been going on at this point for several months, and something permanent appears to have been found. Two stopes are being worked by the Muskett and Wittenberg lease at the Manhattan Consolidated. Rich ore is still being mined in the winze being sunk from the 130-ft. level to the 250-ft. level.

The Tonopah company reports that during July, 13,832 tons of ore was treated yielding \$216,950, of which \$186,850 was the value of bullion shipped and \$30,100 from 65 tons of concentrate. The net profit for the month was \$119,205. During the week ended August 17, seven mines at Tonopah produced 10,201 tons, with an estimated value of \$255,025. The Golden Crown has been purchased by Tonopah men, and a new company has been formed called the New Golden Crown Company of Tonopah, with a capital of 1,500,000 shares of \$1 each. The property is situated between the Montana and Midway mines, and about 600 ft. east of the Tonopah Merger mine. A shaft has been sunk 620 ft., is in order, and has a good steam-hoist which will be used for the present. A compressor will be erected. Sinking will be continued to 1200-ft. depth.

#### STOREY COUNTY

A meeting of the United Comstock Pumping Association was held in San Francisco last week, to confer with the Starret pump people relative to the situation at the Ward shaft, where a pump of that make is trying to unwater the shaft, which was flooded at the time of the fire on the 2475-ft. level some months ago. The Pumping Association granted the Starret pump people reasonable time in which to make another attempt to lower the water; and if they do not succeed, some decisive action may be taken regarding the future of the Ward shaft, which has been a heavy burden upon assessment payers of the entire Comstock lode, particularly on the properties at the north end. At the C. & C. shaft work is being rushed on the new pump, three shifts per day being at work getting ready to lower the new vertical centrifugal pump to the 2500-ft. level. On this level at the Ophir, the south drainage drift is being reopened, and other work done for enlarged pumping operations. A new cross-cut has been started on the 2200-ft. level, 107 ft. in the northeast drift, which runs from the bottom of the 2000-ft. winze. Stopping on the 2400 and 2500-ft. levels of the Mexican is opening good ore. The 2400-ft. stope near the Union line has widened out considerably, and may prove to extend into Union ground on the intermediate level.

At the meeting of the Union Consolidated company on August 20, B. F. Shaw, president and director, resigned, and J. H. Goldman, representing the De Sabla interests, was elected to fill the vacancy on the board. J. Landers was elected president in place of Mr. Shaw. The resignation of

C. E. Julian, the superintendent, was accepted; and Whitman Symmes, formerly superintendent, as well as the present superintendent of the Mexican mine and of the Pumping Association, was reappointed to fill the vacancy. This will place Mr. Symmes in control of the pumping and ventilation of the north end mines, as well as the Mexican-Union-Sierra Nevada joint shaft.

During the week ended August 17 the Consolidated Virginia mined 11 tons of ore, worth \$26.63 per ton, from the understope on the 2500-ft. level. The Ophir shipped 99 tons to the Kinkead mill. From stopes at the 2300, 2400, and 2500-ft. levels the Mexican mine produced 601 tons with a total value of \$18,074. The mill treated 530 tons averaging \$23.10, with 92% extraction. Water in the Yellow Jacket shaft is 36 ft. 11 in. below the 1400-ft. station on the incline.

## NEW MEXICO

### EL PASO COUNTY

The Deadwood Mines mill has been treating 30 tons of custom ore per day in addition to the regular mine output, and when the automatic sampler is erected the capacity of the plant will be much increased. The Ernestine mill produced 4½ tons of concentrate from the first 10-days run in August, while 542 tons of ore was treated during the first week. During the week ended August 16 the Oaks Company shipped 130 tons of ore worth \$20 per ton.

### GRANT COUNTY

The Utter mine at Pinos Altos will ship over 1,000,000 lb. of zinc concentrate this month to Bartlesville, Oklahoma. The mines near Hanover are shipping a good deal of zinc ore.

## UTAH

### JUAB COUNTY

The May Day company is sending zinc ore to the smelter at Argentine, Kansas. About 1000 tons of 37% zinc ore is ready for shipment. The new electric hoist is working well. The Eagle & Blue Bell has let a contract for a 300-ton ore-house. The Grand Central has paid a dividend of \$30,000, the total to date being \$1,632,500. Development at the 2300-ft. level is encouraging, this being the deepest mining in the Tintic district.

### SALT LAKE COUNTY

Seven mining companies paid dividends amounting to \$289,849 in July. Bulletin No. 471-I, the U. S. Geological Survey has given a preliminary though thorough review of the coalfields in Uintah and Wasatch counties. It is estimated that the Deep Creek field contains 49,461,000 tons of coal, and by careful mining at least 60 to 75% can be recovered. The coal is a low-grade bituminous. The Blacktail mountain coalfield, in Wasatch county, is also of a low-grade bituminous character, its calorific value being about 12,000 British thermal units.

After September 1 the wages of miners at the Bingham camp will be increased 25c. per day, which will make the wage about equal to 1907.

### UTAH COUNTY

On the 1500-ft. level of the Lower Mammoth, the lode carrying zinc ore is now 18 in. wide. On this level, 100 ft. west of the shaft, assays return 2.1% copper, \$1.40 in gold, and 24.6 oz. of silver per ton. From a vein being prospected at the 1000-ft. level the assays have shown 239 oz. of silver, 21.5% lead, and \$1.20 in gold; also 17.4% lead, 16.8 oz. of silver, and 80c. in gold. These samples were from the vein, but so far there is no large quantity of ore opened at this point. Shipments are to be made from the Union Chief mine. On the lower adit level the lode in the northeast drift is about 24 in. wide, consisting of iron ore carrying lead, similar in character and value to that in the upper levels, and also has a seam of galena on one wall.

## CANADA

### COBALT

During the week ended August 10, nine mines at Cobalt

shipped 631 tons of ore and two sent out 64,624 oz. silver, the Coniagas heading the list of ore shipments with 208 tons, and the Nipissing with 45,263 oz. silver. For the current year the total shipments of ore and silver from the camp are 6649 tons and 2,969,268 oz., respectively. Foundations have been completed for the new high-grade mill at the Buffalo. It has been planned on somewhat similar lines to that at the Nipissing, where amalgamation and cyanidation are used in a tube-mill. There will be a few modifications of the latter plant. Hydraulicizing at the Nipissing has uncovered a vein which is probably an extension of No. 128.

From the main vein at 150-ft. depth, in the McKinley-Darragh mine, 38 tons of ore was shipped to Perth Amboy smelter, containing 231,270 oz. of silver. Some of the high-grade ore carries as much as 13,000 oz. per ton. The value of this carload is a record for the district. The Minister of Mines announced that that portion of the Gillies Limit open to prospecting on August 20, can be staked on identically the same terms as other Crown lands open for staking, and no special conditions are attached whatever. There was a fear among prospectors that a royalty would of Mines announced that that portion of the Gillies Limit be exacted. Prospectors have been examining the district with much interest.

### YUKON

Indians have found placer gold in the Stikine country, in Yukon Territory, above the northern boundary of British Columbia. A rush has set in for the isolated place, where there are no people, and it is hard to reach. Bishop Du Vernet says that "any attempt to reach the district this winter would probably be inviting disaster." To get there, a coast steamer is taken to Wrangel, Alaska, or failing this, a gasoline boat up the river 160 miles to Telegraph creek, the head of navigation. From here there are pack-trails in four directions. The field is on the South Nahanni river, 450 miles by trail and river from Telegraph creek, beyond the northern boundary of British Columbia, 120 miles east of the Hyland river, across country. The July return from the Yukon Gold Co. amounted to \$641,000, as compared with \$476,844 for July 1911. The average yield for the month was 63c. per yard, and for the season to date, 71c., as against 57c. for the same period last season.

## MEXICO

### SONORA

According to refugees from La Dura, the Mexican rebel leaders, Rojas and Campos, after two weeks of nearly constant fighting, captured and destroyed that town. What the rebels could not carry away they burned.

The Protrero company is erecting a 60-ton stamp-mill, about 35 miles from Casal. About 45,000 tons of ore worth \$15 is ready for the mill. The San Felipe company is employing 25 men, and its shaft is down 280 ft. There have been no interruptions to work through the revolution.

One hundred and fifteen men are employed by the Democrata company, and the smelter of 125-ton capacity will be blown in during the week. Considerable ore has been broken, and over 600 tons was mined in two days in the carbonate stope on the adit-level. The smelter matte will be sold to the Cananea Consolidated company. A 75-ton smelter is to be built for the Minneapolis Copper Co., which owns considerable property in the Moctezuma district, near Campas.

### NORWAY

(Special Correspondence.)—During the month of July the Elmore vacuum plant at the Sulitjelma mine produced 1078 tons of copper concentrate.

London, August 1.

## SOUTH AFRICA

### TRANSVAAL

The Rand output for July was valued at \$16,284,000, as against \$16,012,000 for June and \$15,060,000 for July 1911.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. W. MEIN is in San Francisco.  
F. J. DENNIS is back from Nome.  
T. T. READ is at Spokane, Washington.  
TOM COX was in San Francisco Tuesday.  
STUART L. RAWLINGS is in San Francisco.  
J. E. SPURR was in San Francisco this week.  
S. W. MUDD was in San Francisco last week.  
B. B. THAYER was in San Francisco this week.  
F. A. KEITH visited San Francisco last Friday.  
E. P. MATHEWSON was in San Francisco Thursday.  
R. Y. WILLIAMS is at Seattle on his way to Alaska.  
C. W. PURINGTON sailed from Seattle for Nome this week.  
ELWOOD MEAD is up from Melbourne, Victoria, for a visit.  
W. H. STORMS has returned from High Grade, California.  
R. B. MCGINNIS is back from Arizona and leaving for Oregon.

H. W. TURNER has returned to San Francisco from London.

JOHN H. EGGERS is at the Golden Eagle mine, Fort Jones, California.

T. A. RICKARD and D'ARCY WEATHERBE have been golfing in Belgium.

J. D. HUBBARD is returning from Korea to California for a short stay.

CHARLES JANIN has returned from Alaska and will go to Nevada today.

RALPH STOKES is to assist W. W. MEIN, of the Canadian M. & E. Company.

F. P. PAUL arrived from Sydney on the *Sonoma* last week on his way to London.

P. JANSSEN of the Simau mines, West Sumatra, will be in the United States soon for a vacation.

J. M. HILL has been studying High Grade, Modoc county, California, for the U. S. Geological Survey.

E. J. DUNN, for many years director of the Geological Survey, of Victoria, Australia, recently resigned from the service.

HYMAN HERMAN, a well known Victoria geologist, has been appointed director of the Geological Survey, of Victoria.

W. H. WESLEY, assistant metallurgist at Mt. Lyell, Tasmania, has been appointed metallurgist for Mt. Morgan mine, in Queensland.

F. A. LEACH is again in government service, having taken the place as superintendent of the Mint at San Francisco, made vacant by the death of JOHN SWEENEY.

W. A. MCLEOD, formerly of the Charters Towers School of Mines, but lately with the Brilliant Extended company, has been appointed to take charge of Bewick, Moreing & Co.'s business in Western Australia, in place of J. A. Agnew, who recently resigned.

## Obituary

VICTOR DE GOMEZ, long associated with Hagin & Hearst in the management of mines, died at Durango, Mexico, August 8, of dysentery. Mr. Gomez was an old army officer who spent the past quarter of a century in Mexico and had an excellent reputation for ability and integrity. He was a man of fine nature, who made and held friends, and he will be greatly missed.

WILLIAM POLLARD, one of the best known mining 'captains' in the Michigan copper mines, was killed by a fall of rock last week. Mr. Pollard was from Cambourne, Great Britain, but had been in this country since 1887. He had worked at the Ahmeek, Centennial, Calumet, and other properties before going to the Wolverine, where he had been employed for the past dozen years, and had also had experience in Arizona. He was 52 years old and leaves a wife and eight children.

## Market Reports

### LOCAL METAL PRICES

San Francisco August 22.

Antimony .....	11-11½c	Quicksilver (flask) .....	42.50

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**M**ANGANESE dioxide amounting to 15% of the weight of gold precipitate from a cyanide clean-up may be used with good results in a clean slag and better grade of bullion than usual.

**I**NTERMITTENT washing of sand in a leaching vat has often been found to give better results than continuous leaching, as in the former system the sand gets extra aeration when the washes are completely drained.

**B**REAKAGE of cams does not form any great expense in a well run stamp-mill. At Treadwell, only 42 were broken out of 540 in use last year; while at the Ivanhoe, at Kalgoorlie, the average is 19 out of 100 in use.

**H**ORSE-POWER totaling 2095 is generated by high and low-pressure turbines and generators at the Horse-Shoe mine, Kalgoorlie. The output for 1911 amounted to 7,363,300 units, at an average cost of 1.5c. per unit.

**G**AS made in an ordinary producer, for a suction gas-engine, is used with much satisfaction for melting bullion at Waihi at a cost of 8c. per hour. Kerosene melting furnaces to take a No. 200 crucible are also used in the district for melting precipitate.

**M**EN working in mills and smelters should have plenty of light, and fairly comfortable surroundings, if they are expected to be contented and to work efficiently. Men cannot be blamed if they neglect to pay enough attention to machinery in dark corners, where danger lurks.

**S**ELECTIVE action of cyanide solutions is at its maximum in solutions of greater dilution than are found most economical in regular working; but fortunately, great solvent effect is exerted by small concentrations, and the cost of cyanide per ton of ore is therefore low.

**G**ROOVING of crushing rolls is the cause of much expense in that thick shells have often to be discarded. In order to reduce this trouble in the new rolls made for the Miami Copper Co. by the Traylor company, the free roll is automatically moved backward and forward.

**D**ISPOSAL of residue from vacuum or filter-press plants may be cheaply done where water-power is used in driving machinery. The tail-races, carrying waste water from Pelton or other wheels, can often be constructed under the leaves or frames of such filtering machines, and the residue thus washed away into creeks or ponds.

**M**ACHINERY has a certain noise when working, and attendants quickly note any unusual sounds, knowing that all is not right. The same applies to the feel of certain working machinery. A millman has been known to pass along and feel 100 stamps dropping, pick out one and say that it was not quite correct. When inspected, a small piece of steel was found under it.

**S**OOT has been the cause of considerable investigation and discussion. According to R. C. Benner, professor at the University of Pittsburgh, laundry articles to the value of \$500,000 are destroyed yearly by the smoke of that city. Lace curtains last one-third longer in other cities, and over 20% of the dust in its streets is composed of soot. A cubic mile of Pittsburgh air contains 4½ lb. of soot.

**C**OCONUT matting in leaching-vats is sometimes laid over the filter-bottoms, with the cloth caulked down over it; and sometimes the reverse way; that is, the cloth is caulked over the bottoms, and the matting is laid on top of it. It is mostly a question of experience as to which system preserves the filter-cloth longest. When the sand is shoveled out of a vat, light boards are sometimes put over the filter to prevent its being cut.

**G**AS is not a mineral, according to the decision of the Privy Council in the case of Farquharson v. the Canada Land County. The Indiana Supreme Court once held that gas was a 'wild' mineral comparable to wild game and belonged to the man on whose land it was found, if captured and brought under restraint while still on his land, but, unlike the domestic cow, could not be followed and claimed if it strayed down the country lane.

**S**AND-FILLING of stopes is practised at many mining centres, both by using dry sand and by pumping in wet pulp. On the continent of Europe it is known as the flushing system, in which old rubbish and fine coal is used. At Treadwell a large proportion of the power generated at Nugget creek is to be used for pumping the tailing from the stamp-mills to the mine stopes, thus preventing a possible settling or caving of the ground.

**S**AMPLING pulp from a battery, before it goes over copper plates and to the cyanide plant, is an easy matter if the ore has been crushed with water. At some mills it is the practice to take a cut of the pulp stream, by drawing across it a small scoop which discharges the sample into a barrel or other receptacle. This is done hourly; and on pulling the sample the reverse way, another sample may be obtained to check the first one. At one mill in particular, results check well right through treatment, using this sampler.

**O**IL and hard water are generally troublesome in boilers, and various devices are used to protect the latter from oil and scale, such as passing condensed water from engines through a box in which the oil is deposited on thin cast plates by an electric current; passing oily water through a series of tanks containing coke, bricks, and straw; the use of alum; boiler compounds containing soda as a base; passing hard water over sheets of aluminum exposed to sunlight; hanging slabs of zinc in boilers; and after a boiler has been cleaned, coat the inside liberally with graphite.

**M**INING BOOMS generally result in inflating, out of all reason, the prices of blocks in new townsites thrown open. When the district settles down to steady work, there is invariably a slump in land values. A case in point is the well known Bullfinch boom, in Western Australia, in 1910. The Government sold 128 town blocks at prices up to \$4000 each. A 10% deposit was required, followed by monthly payments. It appears now that only 34 blocks have been paid for, and the rest will be forfeited. The original sale days were ones to be remembered at Southern Cross, the main business centre of the district.

**C**ERTAIN creeks and rivers in New Zealand have been declared sludge channels by the Government, so that mining companies are allowed to discharge their battery residue into them. When such rivers are flooded, the slime and sand is carried many miles, and if low-lying farming country is near, these products are deposited on it, much to the alarm of farmers. An instance of this is the Ohinemuri river, flowing through the Waihi and other mining districts of New Zealand. A silt commission was appointed and a deal of interesting evidence taken. The companies discharging into the river have now to pay a small sum annually.

## Utah Copper Quarterly Report

The report of the Utah Copper Co. for the second quarter of 1912 gives the gross production of total copper contained in concentrates as follows:

	Pounds.		Pounds.
January 1912....	8,156,162	April 1912.....	9,069,237
February " ....	8,612,739	May " .....	10,068,336
March " ....	8,160,199	June " .....	9,234,465
Total .....		Total .....	
Average month-		Average month-	
ly production 8,309,850		ly production 9,457,346	

During the quarter there was treated at both plants a total of 1,503,884 tons of ore, as compared with 1,299,315 tons for the previous quarter. Of this tonnage, the Magna plant handled about 70% and the Arthur plant about 30%. The average assay of the ore treated during the quarter was 1.42% copper, as compared with 1.435% copper for the previous quarter. The average cost per pound of net copper produced during the quarter, after allowing for smelter deductions and without crediting miscellaneous income, was 8.127c., as compared with 8.62c. for the first quarter of 1912. If net miscellaneous earnings in Utah, including those from the Bingham & Garfield railway, were applied as a reduction of costs, the net cost per pound for the quarter would be 7.55c. The financial results of the operations of the company for the quarter are shown in the following table:

Milling profit for quarter.....	\$2,237,485.24
Other income, rents, etc., in Utah.....	10,026.01
Income from Nevada Con. Copper Co. dividends	375,187.50
Total net profit for the quarter.....	
\$2,622,698.75	
Dividends paid .....	1,181,347.50
Net surplus for the quarter.....	
\$1,441,351.25	

The earnings are computed on the basis of 16.43c. per pound, which is approximately 0.15c. less than the average net price received from actual sales during the period. At the close of the quarter, no copper due for delivery from the refinery remained unsold.

The Magna plant and nine of the thirteen sections of the Arthur plant were in operation throughout the month of April, but their tonnage was much reduced by reason of the numerous snowstorms during the month, causing some delays in the coarse-crushing departments on account of wet ores. During the month of May conditions were more satisfactory, and both plants were operated continuously to full capacity for the sections then in commission. During June the Magna plant was operated to full capacity, but the tonnage of the Arthur plant was considerably reduced on account of the installation of new and heavier machinery in the coarse-crushing department. The tenth remodeled section of the Arthur plant was finished and placed in operation about the middle of May, and the eleventh section about the middle of June. The twelfth section of this plant is ready for operation, and the thirteenth and last remodeled section will be completed about the middle of August. This will conclude the heavy expense of rebuilding the Arthur plant and leave, for the completion of both mills, only the enlargement of their coarse-crushing departments to insure sufficient capacity during winter and wet weather when the ores are more difficult to handle in these departments. The expense of these improvements will be comparatively nominal, and it is expected to have them completed before winter weather begins. The snowstorms during the month of April interfered materially with the stripping operations, but in the months of May and June good progress was made, as weather conditions were favorable. There were removed for the quarter a total of 1,589,648 cu. yd. of capping, as compared with 1,354,761 cu. yd. removed during the first quarter of 1912, being an increase of 234,887 cu. yd. The operations of the Bingham & Garfield railway during

the quarter were satisfactory in every respect. An average of 10,203 tons of ore per day was hauled from the mines to the mills for the period, as compared with 7910 tons per day for the previous quarter. An average of 1265 tons per day of other freight was transported over the line compared with 571 tons per day for the first quarter of 1912. Passenger train receipts for the quarter also showed a substantial increase, as compared with the previous quarter.

## Mining in British Columbia in 1911

The annual report of the Bureau of Mines, by the provincial mineralogist, W. F. Robertson, shows that the total value of all products in 1911 was \$23,499,072, being a decrease of \$2,877,994 as compared with the previous year. Up to and including 1911, the province has yielded \$397,-696,722. The following table shows quantities and values of the mineral products for the year:

	Quantity.	Value.
Gold (placer), ounces .....	228,617	\$ 426,000
Gold (lode), ounces .....	1,892,364	4,725,513
Silver, ounces .....	26,872,397	958,293
Lead, pounds .....	36,927,656	1,069,521
Copper, pounds .....	2,634,544	4,571,644
Zinc, pounds .....	2,193,062	129,092
Coal, long tons .....	66,005	7,675,717
Coke, long tons .....		396,030
Miscellaneous .....		3,547,262
Total .....		\$23,499,072

For a period of eight months there was no production of coal from the East Kootenay district, owing to a labor dispute, hence production fell off by over 600,000 tons, and that of coke by 152,000 tons. This trouble had its effect on the mines and smelters in the Boundary district. Lode mines produced 1,770,755 tons during the year, a decrease of 445,673 tons, the Boundary district yielding 70.25% of this total. The Atlin camp produced \$225,000 in placer gold. The snowfall of last winter was above the average, but it was not followed by the usual spring and fall rains, this preventing several fall clean-ups. The Cariboo and Quesnel divisions show a decrease of \$54,000. Rossland with \$2,411,837, Boundary with \$1,813,690, and Slocan with \$364,619 gold output, made the total from lode mines. The Nickel Plate mine at Hedley treated 57,500 tons with a return of \$675,000, in its large stamp-mill. There are stamp-mills in other centres. Most of the silver produced in British Columbia is found with the lead ores in the Slocan district. The Fort Steele division produced 63.82% of the lead ores, Slocan following with 24.96%. Owing to the labor dispute, the copper output from the Boundary district was about 9,000,000 lb. less than last year. The Grandby mine produced only 605,880 tons of ore, as against 1,075,000 in 1910. But the Coast district had an increase of about 7,900,000 lb. The average assays of copper ores based on copper recovered were: Boundary, 0.89%; Coast, 3.67%; and Rossland, 0.67%. The Van Roi and Hewitt mines produced most of the zinc, the Whitewater and Lucky Jim mines not being able to ship on account of loss of rail connection due to a fire. Details are given on the yield and prospects of iron and platinum, and production of building materials.

## "Notice---This Means You"

The *Chicago Tribune* prints the following as posted at a New Mexico coal mine:

"Notice to all employees  
aney Person or Persons that Mooves into A house With-out My Consent shall be Put out Without anney Cemmony.  
Dam it I Must and Will have some Sistom.

HEN FILSTER."

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### ORE REDUCING CONTRACT—SUIT FOR ACCOUNTING

Where a contract was made with an ore-reduction company to reduce ores at a specified sum per ton, and a suit was thereafter brought for an accounting based upon the entire gross value of the ore, a judgment for the plaintiff for the full amount was reversed, the appellate court announcing that it would take judicial notice of the fact that there could not be 100% extraction, and that the percentage of extraction would have to be determined on a new trial.

*Richardson v. National Ore Purchasing & Reduction Co.*, (Nevada) 124 Pacific, 779. July 13, 1912.

### OIL LEASE—CONSTRUCTION

An oil lease provided for stipulated payments to the lessor for the lessee's failure to commence drilling, and also provided that the lessee might suspend drilling operations if the price of oil went below 75 cents per barrel. When the lease was executed, the price of oil was below 75 cents per barrel and thereafter remained below that price. It was held that the lease merely authorized a suspension of drilling operations and did not authorize a failure on the lessee's part to commence drilling.

*McComber v. Kellerman* (California), 124 Pacific, 431. June 4, 1912.

### DRAINAGE OF MINES—LIABILITY OF UPPER OWNER

The owner of a mine on a higher level may permit the water to flow where it naturally will, in the course of ordinary mining, and is not bound to protect a mine-owner upon a lower level from such water, and if an injury is caused from such natural flow of the water from the higher level to the lower, there is no liability; but if the owner of a mine on a higher level opens up old workings which he knows or has reason to know may be filled with water, or otherwise allows or causes water to flow into the lower mine which would not ordinarily go there, he is liable for resulting damages.

*Spadra Creek Coal Co. v. Eureka Anthracite Coal Co.* (Arkansas), 148 Southwestern, 644. June 17, 1912.

### ADVERSE CLAIM—SCHOOL LAND—ASSESSMENT WORK

Where a mining location was made upon a section 36, granted to the state of Utah as a school section prior to date of location, it was not necessarily invalid as being on land presumed to be non-mineral. If the officers of the Land Department have recognized the claim as being located on mineral ground, the character of the land cannot be assailed in an adverse suit in the courts. The findings of the Land Department are conclusive in this respect. Where it is shown that the land was known to be mineral in character prior to the passage of the Congressional Act purporting to grant it to the state, no title passed to the state under such a grant. Where in an action in aid of an adverse claim, there was direct and positive evidence from expert miners and mining engineers that the assessment work had been properly done, the trial court properly refused to substitute its own judgment therefor, even though evidence was introduced tending to show that the shaft was too far distant from some of the claims or that the drift run from said shaft would not tap said claims at an appreciable depth. The requirement is merely that the work commenced should be such that, if continued, will lead to the discovery and development of supposed veins, or facilitate the extraction of ores known to exist. A finding of the trial court that the claim was not forfeited for non-performance of assessment work will not be disturbed on appeal unless clearly shown against the preponderance of evidence.

*Nevada Exploration & Mining Co. v. Spriggs*, (Utah) 124 Pacific, 770. June 10, 1912.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**CHEMICAL ARITHMETIC AND CALCULATION OF FURNACE CHARGES.** By R. Chauvenet. 300 pp.; index. The J. B. Lippincott Co., Philadelphia. For sale by the *Mining and Scientific Press*. Price \$4.

This volume will be found to be useful to students, and anyone connected with chemical or smelting works. The opening pages contain the usual laws of chemistry, definitions, and explanations of thermometers and the metric system found in other works, but given here in a condensed form with examples of problems. Under chemical problems, there are given, among others, the equation for determining the weight of any other substances, the actual weight of one substance entering into a chemical reaction being known; given the formula of a chemical compound, to deduct its analysis, or composition expressed in percentages; given the analysis of a chemical compound, to derive its formula; given the equation for the production of a gas, and the weight of any one of the solid compounds entering the reaction, to deduce the volume of the gas; given the volume of a certain mass of gas, to find the volume under a given change of pressure. Under these and other heads are given a number of problems coming under the fundamental laws of chemistry. A variety of specific gravity problems is given, and explained. There are discussions on calculation of analyses, and assay weights and calculations in a simple style. Under volumetric analysis, 41 examples are explained, while 255 miscellaneous questions and answers are given on all chemical problems. Twenty-two pages are devoted to tables of all kinds. The calculation of furnace charges is an important feature if good results are to be obtained in smelting plants, and in the work under review great space is devoted to examples of fluxes used and slags desired, especially in the part dealing with pyritic smelting.

## Recent Publications

### BUREAU OF MINES NEW PUBLICATIONS

Bull. 18, 'The Transmission of Heat into Steam Boilers.' By Henry Kreisinger and W. T. Ray. 180 pp. 1912.

Tech. Paper 17, 'The Effect of Stemming on the Efficiency of Explosives.' By W. O. Snelling and Clarence Hall, 20 pp. 1912.

Tech. Paper 18, 'Magazines and Thaw Houses for Explosives.' By Clarence Hall and S. P. Howell. 32 pp., 1 pl. 1912.

Tech. Paper 23, 'Ignition of Mine Gas by Miniature Electric Lamps.' By H. H. Clark. 5 pp. 1912.

Bull. 40, 'The Smokeless Combustion of Coal in Boiler Furnaces.' By D. T. Randall and H. W. Weeks. 188 pp. Reprint of U. S. Geol. Surv. Bull. 373, revised by Henry Kreisinger.

Tech. Paper 21, 'The Prevention of Mine Explosions.' Report and recommendations by Victor Watteyne, Carl Meissner, and Arthur Desborough. Reprint of U. S. Geol. Surv. Bull. 369.

The Bureau of Mines has copies of these publications for free distribution, but cannot give more than one copy of the same bulletin to one person. Requests for all papers cannot be granted without satisfactory reason. In asking for publications, please order them by number and title. Applications should be addressed to the Director of the Bureau of Mines, Washington, D. C.

## EDITORIAL

CONGRESSMEN are at last free to go home and rebuild their dilapidated fences. Before they are through many planks are apt to be missing from party platforms.

CERRO, New Mexico, is the most recent district to bid for fame and prosperity by means of an artificially created boom. There are real veins in the district and some chance of finding orebodies of importance, but Denver papers report that the recent flurry was created solely by men owning hotels and livery stables at Cerro and Questa, on the route.

REDUCED rates have been granted by the Western Passenger Association for the meeting of the American Mining Congress at Spokane, November 25 to 30. The fare from Missouri river points will be \$52.50 for the round trip, and that from Chicago will be \$68.80. Tickets will be on sale November 9, 10, 11, 21, 22, and 23, with a final return limit of December 31. This granting of reduced rates out of season is an unusual favor, and the officials of the Congress are to be congratulated upon being able to make the arrangement.

METAL-MINING problems are after all to be investigated by the United States Bureau of Mines, Congress having, in the final adjustment of the Sundry Civil bill, granted \$50,000 for the work. There is a large and important field to be cultivated, and with such good engineers as Messrs. F. G. Cottrell and W. J. Sharwood in the service, work of definite value is assured. The Director of the Bureau, Mr. J. A. Holmes, might well have become discouraged at the long and persistent fight waged against this item in his estimates. Fortunately, his enthusiasm is of the unquenchable sort, and fortunately also, the wiser counsels prevailed in the final framing of the much-contested act.

HOW deep does the ore extend? That is the critical question in considering most mining investments. The very fact that the question is asked illustrates that experience has taught that ore-shoots are limited in depth to an extent that may be decisive in determining the purchase of a property. Systematic collection and tabulation of observations on this line are much needed. Mr. T. A. Rickard has performed a real service in bringing together the material embodied in his two articles, of which we print the second part this week. We well remember some years ago when he, while state geologist of Colorado, delivered an address at the State School of Mines in which he attacked the ancient fallacy that 'true fissure' veins become richer with depth. There was loud public outcry that such heresy had no place in the instruction of the young engineers of the state and was sure to discourage Colorado's chief industry. Times have changed, and nowhere is there a keener or more intelligent interest in ore deposits now than in that same state. Facts may be stubborn, but knowledge of facts is essential to sound business. We need more data. Will not the engineers in practice write out

the exact measurements of ore-shoots they have worked, so that the foundation may be laid for better practice and sounder theory?

**D**EFINITE proposals for changes in the organization of the American Institute of Mining Engineers are now in order. The report of the Committee of Five has been before the membership several weeks, and the adjourned annual meeting is to be held in New York October 7. General complaint leads to nothing unless specific constructive measures are proposed. In another column Messrs. C. R. Corning and George C. Stone make such proposals. Discussion of the subject will be welcomed by the officers and all loyal members of the Institute. We shall be glad to print letters from our readers who are interested.

### Civil Service and Pensions

Vetoës serve frequently a good purpose, and however much any may differ from Mr. Taft as to points of policy, there is general approval of his continued interposition of the veto to defeat general legislation tacked on to general appropriation bills. This method of forcing through doubtful legislation has become entirely too common, and the President does well to stand for the principle that important matters must be settled on their merits. A case in point, that did not receive deserved recognition, was the proposed limitation of appointments in the civil service to seven years. It is contended that this was merely a device to reintroduce the spoils system, and there is little doubt that the provision, if enacted into law, would have had such a tendency. We do not believe, however, that this was the intention of Congress. As it stands now the civil service is a great organization for building up a corps of employees of mediocre ability. The requirements for entrance are sufficiently severe to prevent more than an occasional inefficient worker obtaining a place, but, on the other hand, there is neither adequate recompense for the man of exceptional ability, nor means of disciplining or dismissing the lazy or incompetent. One administrative officer, long in the government service, said, when several of his men resigned to go into private work, that he would not regret quite so keenly the loss of good men if he were permitted at the same time to dismiss an equal number of poor ones, and thus to maintain the average. Practically that cannot be done, though theoretically it is possible. With all due respect to the many excellent and conscientious men in the government service, it may be fairly stated that the majority of the good men either are financially independent and are therefore able to stay in comfort, or that they keenly regret not having resigned while still young enough to make places for themselves outside. This is not right, and is poor business besides. The government service, affecting as it does most intimately the common good, should be made attractive to the best young men and women in the nation. It should not be necessary for anyone to have private means that he serve his country.

The conditions outlined are thoroughly familiar to everyone who knows life at Washington and to many who come into contact with government employees elsewhere. It continues because of an assumed popular prejudice against civil pensions. A Congress that votes thousands of private pensions to deserters and bounty jumpers, that increases the pension roll \$75,000,000 per year by one act, still hesitates to pass a civil pension bill for fear of public wrath. The very excesses in the present military pension system, prevent introduction of a reasonable and business-like system of pensions for civil employees of the Government. More than one bureau chief has estimated that by retiring on

half-pay the superannuated employees he has inherited, work could be accomplished more rapidly and money saved to the Government. As it now stands, the old employee either draws full pay or nothing, and in a choice between the two, the bureau chief naturally continues the pay as long as the man can be present and even pretend to work. There is no reason in good morals or in business why a man who has spent his life in the civil service should be turned out to starve. In the military and naval branches of government service, while salaries, as in the civil service, are moderate, ample provision is made for a decent old age. At the same time it is to be remembered that army and navy officers are educated at the expense of the Government, while men in the Geological Survey, Bureau of Mines, Reclamation Service, and other branches, must fit themselves for their work at their own expense.

Congress proposed to meet the difficulty by automatically discharging everyone at the end of every seven years. That would prevent anyone becoming old in the service, but it would also disrupt any organization and greatly increase the already sufficiently difficult task of the bureau chief who is trying to accomplish results efficiently and economically. It was a cowardly evasion of responsibility. To vote an unheard of increase in pensions on account of a war that occurred a half century ago, and then solve the problem of the old clerk by firing him into the street, is a fair measure of the 'statesmanship' of the men who framed the Sundry Civil bill of 1912. We frequently blame government officials for being slow and the bureaus for being inefficient. It would be well occasionally to look beyond to the body that determines conditions under which government officials must work. When your Congressman solicits your vote this fall on the basis of having secured large slabs of pork for his district, why not ask what he has done to accomplish economy and efficiency in the conduct of this, our common business?

### Alaska Gold Mines Company

As already foreshadowed last week in our columns, a new company has been formed to hold a majority interest in the Alaska Gastineau Company and to supply funds for equipment and development on a large scale. The sponsors for the concern are Hayden, Stone & Company and the engineers reporting on it, and participating in the flotation, are Messrs. D. C. Jackling and A. F. Holden. On another page we publish a brief extract from their report covering estimates of the size of the orebody, cost of operation, and profits, and in our news letters from New York and Boston, additional details are given.

The Alaska Gastineau Company was but recently formed through the efforts of Mr. B. L. Thane and Mr. W. P. Hammon, who effected a consolidation of ownership of the Alaska Perseverance mine, certain adjacent claims, conflicting apex rights, and important water-rights, the whole lying in Silver Bow and Sheep Creek basins, back of Juneau, Alaska. The lode running through the properties is large and well known, and the Alaska Perseverance has long been regarded as a prospective big mine. With threatened litigation regarding the apex, with insufficient capital, and without the water necessary to run more than a few months each year, the property missed the success to which the size of the lode justified expectations. In the Alaska Gastineau Company were brought together all the properties necessary to economical working of the mine, and now the Alaska Gold Mines Company is to furnish the necessary capital. The Alaska Gastineau Company is capitalized at \$12,000,000, and in addition has outstanding \$3,500,000 of 6 per cent bonds. The company has a 100-ton mill and has

been operating four to five months in the year. With a gross recovery of \$1.50 and a cost of \$1, the earning capacity has been not more than \$40,000 per year. It is understood that interest on the bonds is in arrears and the stock has been held at a low price. As full reports are not available to the public it is not known how much stock remained in the treasury. Interesting details of the plan for financing the property through the Alaska Gold Mines Company have been given in a circular distributed by Hayden, Stone & Company. Many important facts are, however, left unexplained, and in the interest of sound mine financing more information should be given the subscribers for the stock.

The new company is to be capitalized at \$7,500,000, represented by 750,000 shares having a par value of \$10 each. The company is to hold \$1,790,000 in the bonds of the Alaska Gastineau and \$9,801,000 par value of its stock. The underwriters offer 614,700 shares of the Alaska Gold Mines Company to the public and agree to turn over from the proceeds of its sale, \$1,250,000 to the Alaska Gastineau and \$3,250,000 to the Alaska Gold Mines. The remaining shares of the Alaska Gold Mines Company, amounting to 135,300, are to be held in the treasury for general purposes and to buy, if it can be done on reasonable terms, the outstanding \$1,710,000 in bonds, and \$2,199,000 in shares of the Alaska Gastineau. From the last statement it is evident that Alaska Gastineau bonds and stocks are held by the underwriters to be worth much less than par, or that Alaska Gold Mines stock is expected to command a large premium. We are reliably informed that the promoters of the new enterprise paid \$1,000,000 in cash for the \$1,790,000 in bonds and an option on \$9,801,000 in stock of the Alaska Gastineau Company, which is to be placed in the treasury of the Alaska Gold Mines Company. At what price, and for what consideration, these securities were transferred from the promoters to the new company is not made clear. It is true that, assuming that the new stock be sold at par (it is now quoted at \$7 or \$8 in Boston) there would be a profit of \$1,670,000 in underwriting the issue. Possibly the \$1,000,000 already advanced is to be taken out of this profit, but in view of the small chance that the new stock will go out at par, and the expenses and commissions usually incident to underwriting, this does not seem likely. If we are correct in the latter surmise, the new company starts with a debt of \$1,000,000, direct or indirect, which is not mentioned in the announcement. Another point upon which light is desirable is the consideration for which the Alaska Gold Mines Company, in return for its shares sold by the underwriting syndicate, permits \$1,250,000 to go direct to the Alaska Gastineau Company. Is this for treasury shares or bonds, and, if so, what part do they form of the total holdings of the new company? Still another point is, what is the method by which the \$3,250,000 to be paid by the underwriters to the Alaska Gold Mines Company, is to pass to the Alaska Gastineau, and becomes available for construction and development? If our information is correct, to the effect that the promoters turned in an option on the stock rather than the stock itself, and if, further, this stock is still in the treasury of the Alaska Gastineau Company, it is presumed that the latter will receive the cash in payment for stock. The circular distributed by the underwriters is as interesting for what it does not tell as for what it reveals, and is surprisingly vague at critical points.

It should not be forgotten that the property will be expected to pay profits on a total capitalization of \$15,500,000, and that no allowance is being made for amortization. Granting that the 50,000,000 tons of ore 'indicated' measures the tonnage that will be milled, and that the profit per ton will be between 50 and 75 cents, allowance must still be made for the rate at which this profit will be earned. The plant

will wear out, and the bonds, presumably, are to be retired. A 6 per cent dividend on Alaska Gastineau stock would be roughly equivalent to 10 per cent on Alaska Gold Mines. On the proposed scale of operations, and not allowing for extensions of orebodies—offsetting the fact that 50,000,000 tons is 'indicated' and not 'ore reserve'—the life of the mine would be 25 years, and at 50 cents per ton profit the earnings would equal 7 per cent on the capitalization. At 75 cents profit, the rate would be 10 per cent. Assigning equal value to the stocks and bonds and assuming a 7 per cent dividend with reinvestment at 4 per cent, the present value of the mine on these estimates and with a profit of 50 cents per ton is \$10,691,200; at 75 cents this becomes \$17,226,800. Evidently the profits in the enterprise are dependent on reducing costs and increasing capacity. These calculations, it need hardly be said, are not for those who buy shares with the expectation of selling them at a profit on the basis of a temporary high dividend rate.

Turning from the financial to the engineering phases of the new project, the prospect is more alluring. The mine is to be opened by an 11,000-foot adit, tapping the orebody 700 feet below present workings and permitting direct transport of the ore to a 6000-ton mill to be built on the beach. A large hydro-electric plant is to be built, and while ultimately steam generation will be necessary, there is believed to be enough water-power to run the first mill the year around. Working on the present small scale, costs have been reduced to \$1 per ton, and at the Treadwell, hoisting from 1600 feet, ore has been mined at a cost of 90 cents. It does not seem impossible that the expectation of mining Perseverance ore at 75 cents will finally be realized, but even at \$1 per ton there would be substantial profit, provided the new milling plans are successful. The main recovery from the Perseverance mine has been by amalgamation and in a concentrate containing about 20 per cent lead. This has been saved by careful classification and use of James tables. It is understood that in the new mill the ore is to be quickly 'roughed out' so as to get rid of the large amount of waste promptly. It will be a pretty problem to do in a large mill working for capacity, what has been accomplished by slow careful work in a small plant; and the total amount recoverable is too small to allow much shrinkage. Cost of the new adit is estimated at \$440,000; a hydro-electric plant to furnish power for a 2000-ton mill was figured at \$300,000, and for the 6000-ton mill now proposed will be proportionately larger. In the Treadwell mine it costs \$300,000 to open a level, and several must be opened at once to keep up a 2000-ton production. To prepare for 6000 tons per day at the Perseverance may well cost \$1,000,000 for underground development aside from the adit. While the money which it is proposed to expend therefore seems large, it is not out of proportion to the task. Incidentally it may be noted that with the Alaska Gold Mines, Alaska Juneau, and the Treadwell groups operating, a couple of years will see in the Juneau district a series of mines comparable in tonnage handled to the largest on the Rand. In May 1912, the East Rand Proprietary hoisted 183,939 tons and the Crown Mines 190,055. The Treadwell group the same month crushed 144,221 tons, and the Alaska Gold Mines will be equipped with its first unit, to handle 180,000 tons. While the Alaska Juneau is beginning more modestly, it is expected finally to rank with the others. Another matter of general interest is that large-scale production at the Perseverance mine will make available on the Pacific coast a supply of lead concentrate that may materially affect smelting conditions. Mr. Thane and Mr. Hammon have been interested in Alaska for some years, and with Mr. Jackling and Mr. Holden will form an active and able group sure to be prominent hereafter in the Far North.

## Persistence of Ore in Depth—II

By T. A. RICKARD

In controverting the old idea, now proved a fallacy, that lodes become richer in depth, we must not swing too far in the opposite direction. Since man has had the full aid of modern mechanical science for sinking, hoisting, and pumping, he has never yet had to desist from following rich ore in depth. In many cases he has satisfied himself that the ore 'petered out' underfoot, that is, it became too poor or too patchy to be exploited profitably. Yet there exist deep mines that have not bottomed the ore, such, for example, as the Morro Velho mine, of the St. John del Rey Co., in Brazil. This is 4926 ft. deep vertically and 7000 ft. on the dip of the vein. The mine is still profitable at this great depth, the yield during the past year being at the rate of 45s. 10d. or about \$11 per ton on an output of 192,600 tons. The net resultant profit was about 6.6s. or \$1.58 per ton. The main shaft is still being sunk, so that in this case the pursuit of ore in depth has not been abandoned.

Another more important case is the Kolar goldfield, in India, where the Mysore, Ooregum, Nundydroog, and Champion Reef mines have workings that are 3100, 2420, 2500, and 3900 ft. deep vertical respectively. These mines have suggested the existence of zones of relative impoverishment and enrichment, they have not become uniformly poorer in depth, and no positive proof exists that the lodes will not continue profitable to a further depth. At the Nundydroog mine, for example, the workings passed through a poor zone in 1898 to 1900; the Ooregum has passed through two such poor zones and is now in comparatively low-grade ore; the Champion Reef was continuously successful until four years ago, since then the profits have been greatly reduced; but the bottom workings are now in ore as rich as that broken in the upper levels; the Mysore mine has escaped similar vicissitudes and is doing as well as ever. These mines, of course, are far from being the deepest existing workings made in search of the metals. The zones of relative poverty and richness appear to be related to structural conditions that in turn are connected with the trend of the ore-shoots, which have a flat pitch. This pitch may be dependent upon the folds in the enclosing schistose rocks. On the whole, I shall ask for more proof than is now available that the Kolar goldfield is distinctly exceptional. I would rather have the gold in the first 3000 ft. of these lodes than that to be found in the next 6000 ft. of quartz, without regard to the increased cost of mining. At Kalgoorlie, in Western Australia, it is also a fact that while general impoverishment is recognizable, yet, once below the effects of secondary enrichment, the lodes have exhibited zones in which the mine workings have been productive for several hundred feet vertically, to be succeeded by barren horizons, giving place again to conditions more favorable to the miner. Despite these departures from uniform impoverishment, the big mines are approaching exhaustion. All experience warrants us in expecting that the lodes of Kalgoorlie, Kolar, and Minas Geraes alike will cease to be profitable to man within a limit attainable by modern machinery. To argue that the Kolar veins will continue to unknown depths is no more reasonable than it would be to expect a man possessed of unusual vitality at 90 to continue with unabated force for another half-century. Increasing age after maturity entails debility and eventual decay of strength; increasing depth below the water-zone involves impoverishment and the eventual cessation of profitable mining.

Before going further it is necessary to recognize differences of geological environment. The most persistently rich lodes are in Archean and Algonkian rocks; they are associated with acid eruptives of the granitic type; they are presumed to be in their primary condition, that is, they owe little or nothing to the secondary enrichment observed

within the water-zone. Thus they are held to be superior to the ordinary vicissitudes of veins of a different origin, namely, those associated with Tertiary eruptives, of which the Nevada and Colorado gold-silver lodes are a familiar type. In the latter case the ore-forming agencies are associated with rocks having a structure proving that they are solidified near the surface, that is, where they were relieved from such pressure as exists deep in the earth's crust; while the eruptives associated with the typically persistent lodes in the Archean rocks have a structure indicative of solidification under great pressure, that is, at a profound depth. If a lode can be proved, by faulting or other structural evidence, to be not much younger than such a rock, then it may be assumed to have a great geologic antiquity and to have been formed so far below the original surface is to be immune to such changes as are due to waters circulating in the shallow zone. Hence some authorities, for instance, Malcolm MacLaren,<sup>1</sup> argue that this question of persistence as it affects the miner is not to be made a generalization. The Archean schists and the Tertiary andesites afford conditions notably unlike; in the one the lodes are so old as only to be modified by profound regional metamorphism; in the other the lodes are young and susceptible to the thermal activities of expiring vulcanism.

While appreciative of the scientific reasoning on which a special plea may be based for lodes associated with rocks of uncommon geologic antiquity, I am not impressed greatly thereby, for it remains to be proved that the rich ore is so ancient as to have escaped modification by the geologic agencies that come into play near the surface. It is fair to ask the mining geologist to remember that it is only the enriched portions of a lode that have economic value to the miner and that such enrichments represent a concentration or re-precipitation necessarily more recent than the lode as first formed. Moreover, the cases that can be quoted as an exception to non-persistence of ore are so few that they hardly suffice to prove a theory. If one lode in the Archean, or in association with ancient eruptives, has continued rich to 3000, 4000, or 5000 ft. vertically, how many in the same terrain have ceased to be productive at shallow depths, even among those that survived the trials of the water-zone?

Physical conditions, as we know them, militate against the persistence of rich ore to a great depth, such as 8000 or 10,000 ft. Pressure and heat increase. The increment of temperature is variable, but it may be taken as about 1°C. for every 90 ft.; the pressure at successive depths is roughly equal to the weight of a column of rock of 2.8 sp. gr. equal in height to the depth in question. A decrease of pressure and temperature is favorable to precipitation; an increase gives greater solvent power to underground waters. Hence, other things being equal, the approach to surface would favor deposition and the distance from surface would promote solution. Solution is necessary to enable the underground waters to collect the metals previous to their transfer and concentration in such receptacles as are provided by fractures, fissures, shear-zones, porous sediments, and soluble rocks. Precipitation, it is true, is often only the effect of interchange, but it is usually the exchange of a less soluble for a more soluble substance.

Beyond the direct results of pressure and temperature, we have to recognize a change in rock structure. Natural sections of strata once buried deeply under later formations indicate that there exists a horizon at which rocks cease to be fragile, that is, they do not crack or fissure, but undergo deformation by pressure. They become plastic. C. R. Van Hise<sup>2</sup> was the first to show the mining geologist the sig-

<sup>1</sup>'Gold,' by J. Malcolm MacLaren. Pp. 76-79.

<sup>2</sup>'Some Principles Controlling Deposition of Ores.' By C. R. Van Hise. Trans. A. I. M. E., Vol. XXX, pp. 31-33.

nificance of this 'zone of flowage' as a limitation to an indefinitely deep water-circulation. The later experiments of F. D. Adams<sup>3</sup> and the studies of Mr. Van Hise unite in placing the zone of flowage at about 35,000 to 40,000 ft. But the effect of this change must be felt at a much less depth. The openings through which mineral-bearing waters circulate, and in which they lay down their metallic freight to constitute the orebodies for which the miner seeks, cannot persist indefinitely. Without them the circulation is too restricted to permit of the wide gathering and intense concentration precedent to ore formation. As the openings become smaller, by the closing of the larger ones; as they approach sub-capillary size and become discontinuous, the circulation of water tends to diminish. When water ceases to circulate it is no longer an agent in forming ore. Of course, gases under high pressure may still be active, but it is not necessary to go into an even more obscure part of the subject, for the lodes exploited today by the miner are for the most part undoubtedly the work of aqueous solutions.

All this bears on the lower fringe of our problem. Man will never be able to test the reasoning on which such deductions are based, for no shaft or bore will be sunk deep enough. We need not go so far. The openings made by the miner give him a good inkling of the facts. The rock penetrated by the deepest workings is harder and drier than that cut near the surface. Every deep mine is dry; what water may be seen on the lowest levels is the drainage from the upper workings. Openings of every sort—whether fissures, faults, or vugs—are less common at 4000 ft. than at 2000 ft. The miner expresses it by saying that "the ground is tight," and it is so dry that the water used by him in drilling must be brought from some upper level or from the surface to the place where he is at work. We have long recognized a 'water-level,' that is, a horizon at which water rises in a shaft if it is not drained by a pump; we have been shown by different geologists how great is the effect of this ground-water in modifying the orebodies found in the shallow zone. On the other hand, the fact that there is also a lower limit to the ground-water has not been overlooked by most geologists. Even Van Hise speaks of 10,000 metres as the bottom of the ground-water or "belt of saturation," and places a limit on the basis of temperature, suggesting that below the 10,000 metres the H<sub>2</sub>O is no longer in liquid form as water.<sup>4</sup> That is 33,000 ft. On the other hand, as I have shown in a previous discussion of this matter,<sup>5</sup> the evidence of mining all goes to prove that the zone of free circulation is relatively shallow.<sup>6</sup> The shallowness depends upon the climatic conditions at surface and the texture of the rocks, for in arid regions the water-level is struck early and the base of the ground-water is reached soon, while in wet districts, especially where snow abounds in winter and thaws freely in summer, the water-level is deeper and the wet ground has a greater vertical extent. No average figures can be accurate, but it suffices to say, for the purpose of illustration, that it is a common experience to "strike water" at 200 ft. and to "get through it" at 1000 ft. A mine foreman will tell you that he is "taking up" the water at the 900-ft. level; he places the big pump where he can catch most of the drainage from the upper workings; and he expects that in the deepest workings he is not going to be bothered by the seepage. The miner has experience to justify him in his fancy that water is a favorable indication of ore. It is not necessary to discuss the

question whether dusty rock is 'dry' in a chemical sense; such rock may contain 3 to 5% moisture; and after that there is still the water of crystallization. But it suffices to point to the important fact that a zone of superabundant water exists, that it is fed by the rain and the melting snow, that it has a well-defined upper limit and an ill-defined bottom, but whatever the particular form of its base, it presents a factor that must profoundly have affected the agencies of ore formation.

It may be profitable to consider the misapprehensions whereby the fallacy of enrichment in depth has originated.

1. The point at which ore is discovered at surface may not coincide with a rich portion of the lode; in other words, the outcrop of an ore-shoot may not be uncovered. In sinking, the shaft may penetrate into richer ore by intercepting an orebody on its pitch. This may give rise to the idea that the lode has become richer.

2. Again, some lodes containing the more soluble minerals are apt to have poor outcrops by reason of weathering and superficial leaching. Thus the copper veins of Butte were first worked for gold because that metal had become concentrated at the outcrop. In depth, the gold diminished and a zone of enrichment, by re-precipitation of silver, gave the district a reputation for the less valuable of the two precious metals. Finally, the silver contents diminished to a point threatening a cessation of profitable mining, and then, at the next horizon, a marked increase in copper, due also to sulphide precipitation, gave Butte a new and much prolonged career of productivity. That career has not ceased, despite the deepening of the workings to 2500 and 3000 ft., because in that locality a series of fractures at successive periods has permitted the descending enriching copper solutions to penetrate to an exceptional depth.

3. In gold mining especially, but in the mining of the other metals also, the shallow zone of oxidized ore is followed by pyritic ore that was long regarded as more refractory than the gossan and therefore less profitable. Hence the downward penetration of the workings might coincide with fewer dividends. But when processes were devised to treat the ore formerly refractory, the successful issue out of this trouble prompted operators again to scout the idea of impoverishment in depth, particularly as the top of the new sulphide zone was usually marked by exceptionally rich ore, due, as we now know, to precipitation of metal derived from the overlying leached and oxidized portion of the lode.

4. A false idea of enrichment may in some cases have been fostered by an improvement in metallurgical treatment, whereby relatively poorer ore from deep workings may have yielded a bigger profit per ton than the relatively richer ore broken at a shallow level.

5. But the main impulse toward the acceptance of the fallacy is due to the commercial optimism of the promoter, the gullibility of the ordinary speculator, and the ineradicable tendency of humanity to chase rainbows. A good example was furnished lately by the statements made by the chairman of the Lonely Reef mine in Rhodesia at the recent annual meeting. He stated that the mine had "increased in values as depth has been attained." He also said that the increase was "quite regular." The official figures indeed showed a progressive enrichment from 16.27 dwt. per ton above the second level to 42.73 dwt. per ton below the seventh level. At the same time the width had increased continuously, so it was stated, from 27 in. to 51 in. of ore. Upon investigation, however, it could be ascertained, from the figures given in the preceding annual report, that the stoping of the richer portion of the reserve in the upper levels had served to confuse the facts. For example, in 1910 the 15,788 tons between the second and third levels had averaged 27.6 dwt., but in 1911, owing to stoping, the tonnage had decreased to 7100 tons, and the grade had fallen to 20.32 dwt., thus making a favorable comparison with the 19,949 tons of ore between the fourth and fifth levels, which had an average assay of 26.06 dwt. Taking each 'lift,' or

<sup>3</sup>On the Limiting Strength of Rocks Under Conditions of Stress Existing in the Earth's Interior.' By Frank D. Adams. *The Journal of Geology*, Vol. XX, No. 2.

<sup>5</sup>'Waters, Meteoric and Magmatic.' By T. A. Rickard. *Mining and Scientific Press*, June 27, 1908. Also 'Water in Veins—a Theory.' *Engineering and Mining Journal*, March 14, 1903.

<sup>6</sup>'The Rôle of the Igneous Rocks in the Formation of Veins.' By James F. Kemp. *Trans. Amer. Inst. Min. Eng.*, Vol. XXXI, pp. 185-190.

<sup>7</sup>*The Mining Magazine*, June 1912, pp. 405-407.

tonnage between levels, when at its maximum, I find the following figures to be correct, as nearly as can be ascertained from the company's reports:

	Tons.	Gold content, dwt.	Assay for stoping width, dwt.
Above 2nd level.....	12,750	13.5	10.1 *
Between 2nd and 3rd level..	15,788	27.6	21.5
“ 3rd and 4th “ ..	14,847	28.2	22.2
“ 4th and 5th “ ..	19,949	26.06	19.62
“ 5th and 6th “ ..	24,155	29.22	22.65
“ 6th and 7th “ ..	25,180	37.66	30.54
Below 7th level.....	8,544	42.73	34.68

This indicates that the ore above the second level is relatively poor, probably by the leaching to which most gold-quartz lodes are subject, for reasons now fairly well understood.<sup>8</sup> Between the fourth and fifth levels a drop in grade is evident. On the whole, however, from the second to the sixth levels, the assay-value is fairly steady, the range being only from 19.62 to 22.65 dwt. for a full stoping width. Below the sixth and at the seventh levels there is a rise in grade to 30.54 and 34.68 dwt. per ton, but on the bottom level the development is not complete and it is likely that the work so far done is in the best part of the orebody. In any event, the mine is still shallow. Unless its history is wholly contrary to that of the other Rhodesian mines, it will give evidence of a character stultifying the reckless assertion of the chairman. His statement, nevertheless, would ordinarily suffice to confirm inexperienced people in the pleasant fallacy that enrichment in depth is normal.

Another sad example of the perversion of fact is afforded by the East Rand Proprietary fiasco. That enterprise is a huge consolidation of mines formed four years ago to the accompaniment of expectations and promises not justified by the evidence then available. That evidence was not made public. In 1907 Frederick Hellmann, then manager of the parent mine that gave its name to the consolidation, was called before the Mining Industry Commission at Johannesburg. His evidence referred to the prospects of the group of mines under his charge and incidentally to the question of impoverishment in depth as it affected the future of the Rand mining industry. The evidence was given *in camera*, but it was published in a Blue Book that must have been known to the directors of the East Rand Proprietary before the consolidated company was floated in 1908. It is also noteworthy that the local technical press avoided giving publicity to testimony of such importance, for Mr. Hellmann testified that a decrease in gold content was “most marked” in “all the mines” with which he was acquainted on the Rand. Even in the Driefontein “the poor zone was much more extensive” than he had expected. On cross-examination, he said frankly: “I refer to the Rand generally. I have been around, and I know the conditions of the deep levels, and I can say generally that you have got a falling grade in depth, and that it is most natural it should be so. You would expect it from the start from the method of deposition. In depth any mine gets poor. That is the history of every gold mine in the world.” The obvious frankness of this reply would be convincing as regards the sincerity of the witness, even to anyone ignorant of his high reputation as an engineer. Here we have one of the most experienced and most thoughtful men in the profession, and at that very time the manager of one of the biggest mining enterprises in the world, testifying most explicitly on the fundamental problem. Yet in March 1910, Sir George Farrar and Sir Lionel Phillips, two of the directors of the East Rand Proprietary company, stated in public meeting to their shareholders that the Angelo Deep had “added to the evidence that the Witwatersrand series were not decreasing in value” in depth. It was also stated by one of them that “if they excluded the surface area down to 200 or 300 ft.,

there seemed to be no evidence whatever that the gold contents at the deepest levels were not fully as high as they were at the surface, or within 300 ft. of the actual surface.” Thus the testimony of Mr. Hellmann is to be regarded as “no evidence whatever,” but shareholders are to accept the confident but amateurish statements of these two gentlemen. Of course, in a technical matter of such importance the opinion of an experienced engineer is worth that of a dozen financiers. Since then I have seen the stope-sections of several of the big mines of the Rand, and I add my testimony to that of Mr. Hellmann. Taking all the mines started on the Rand, but leaving out the oxidized zone or down to about 300 ft., I would rather have the gold in the ore mined in the next 500 ft. than that extracted in the succeeding 1000 ft., and I would rather have the gold extracted in all the productive mines of the Rand for 1000 ft. below water-level than the gold to be won from 1300 ft. to the centre of the earth.

In decrying the perversion of experience, I do not belittle the reasonable optimism that stimulates the miner to take the risks incidental to the search for valuable minerals. Without a hopeful temperament no man can be a miner. But this attractive and necessary characteristic may prove his undoing and the ruin of those who accept his guidance.

More than twenty years ago I remember discussing this subject with my friend, John B. Farish, then and now recognized as one of the most distinguished of the experienced mining engineers trained in the Rocky Mountain region. He agreed with me that it would be well for the Colorado Scientific Society or some kindred technical organization to collect data on the persistence of ore in depth as ascertained by mining, with a view to more light on the subject. But he also suggested that the notes thus contributed by mining engineers should be burnt as soon as read, for fear that the facts might prejudice public participation in mining ventures. This is a view shared by many men, but I am not one of them. It seems to me clear that the art of mining is based upon the application of scientific methods; it is based not on scientific mechanical devices only, but upon scientific ways of thinking. These do not include make-believe in any form; on the contrary, the frank recognition of facts, and of the inductive reasoning that follows logically therefrom, is the only safe guide to the profitable search for ore.

BAHIA, one of the leading states of Brazil, is rich in minerals. Gold is found both in the north and in the south, but has been chiefly worked on the bottom lands of the streams rising in the Serra of Assuruá and the chapadas that form the divide between the rivers Paraguassú and Verde, the richest deposits being those of Genito in the Serra de Assuruá, which are still exploited in a desultory manner. Gold also occurs and has been worked at Arubá, Jacobina, Serra do Sincorá, the rivers Eromadinho and Itapicuré, and at many other points. Diamond mining is still actively carried on in Bahia, though for the most part in primitive fashion. Diamonds are found chiefly at the headwaters of the Jequitinhonha, the Rio das Contas, and the Paraguassú. Diamond mining is the staple industry around the large city of Lençoes, where in 1845 over 400,000 carats were taken from the diggings. Between 1844 and 1848 over 30,000 persons were engaged in the industry in the district of the River Mocugé, an affluent of the Paraguassú. At Aroeiras and Barra da Solidão, Cajueiro, and Cotinguiba Grande, and on all the headwaters of the rivers Paraguassú, Una, Preto, Piabas, Rabudo, Lençoes, and Andarahy, diamonds have been and in most instances still are worked. Copper is found in the vicinity of the Rio das Contas, at the Cachoeira do Inferno, and at other points of the Serra de Assuruá, but at present it is only worked at the Carahyba mines, near Jaguarary, on the river São Francisco. Manganese occurs in many parts of Bahia, but the chief deposits worked are those at Nazareth, within easy reach of the sea. Lead, according to O. A. Derby, is found in the Serras of Assuruá and Acaçuá, and at other points of Chapada.

# The Mason Valley Copper Smelter

By THOMAS T. READ

That unexpected difficulties are usually met in the operation of a new plant, and that alterations are frequently necessary, is well known; so much so, indeed, that recently the correspondent of a well known mining journal, in describing one of the new mills erected at Porecupine, naively remarked that ample provision had been made for changes in the design of the plant. Not all designers make this provision, but this smelter, constructed to treat ores not previously successfully smelted, and which within six months of the time of its blowing in is successfully handling double the expected tonnage, with no delays or shut-

the care and forethought exercised in the choice of the site were justified.

*Ores.*—The smelter is handling at present 750 to 800 tons of charge per day. Of this, the Nevada-Douglas contributed about 350 tons per day, the Mason Valley mine a little less, and the remainder is largely made up by shipments of copper ore from the smaller properties near these two, although about one car of ore per day is received from the Luning district. A small amount of gold and silver ore is also received, and it is necessary to use about 25 tons per day of limestone as flux, as the Nevada-Doug-

FIG. 1. GENERAL VIEW, MASON VALLEY SMELTER, THOMPSON, NEVADA.

downs and only minor changes in the design, is correspondingly unusual. The plant was designed by and erected under the supervision of Jules Labarthe, now its general manager. A. J. McNab is superintendent. To both these gentlemen I wish to express my appreciation of the courtesies extended me during a recent brief visit to the plant.

The Mason Valley smelter, owned and operated by the Mason Valley Mines Co., is at Thompson, Nevada, about two miles northwest of Wabuska, on the Reno-Goldfield branch of the Southern Pacific railroad. The site was chosen after records of the direction of the prevailing wind had been kept for over a year, and is such that for 90% of the time the smoke is carried in the direction of Carson sink, and for only 2% of the time is carried in the direction of the agricultural districts along the Walker river. At present this is an almost unnecessary refinement, for the sulphur content of the smelting mixture is so low that the escaping smoke carries very little  $\text{SO}_2$ , while arsenic and similar deleterious elements are absent. 'Smoke farmers' need but little cause for complaint, however, and

las ore is rather silicious. The ore arrives at the smelter over the standard-gauge line of the Nevada Copper Belt railway, in 50-ton hopper-bottom cars, and is dropped into one of the two bins of the sampler. The general plan of the smelter is shown in the illustration. From these bins the ore is drawn directly into the throat of a No. 8, style K, Allis-Chalmers gyratory crusher, the crushed product being elevated to the top of the building by a manganese-steel chain-bucket elevator. This type of elevator was first used at the smelter at Trail, B. C., and is found to give longer service at a less cost. At the top of the building a Vezin sampler takes out one-tenth as a sample, the reject passing over a small grizzly, which screens out the fine sulphides and diverts them to a small bin on the rear side of the building. For reasons which will be explained later, this is not now in use, the grizzly being covered with a steel plate. The reject passes by a belt to the main 20-in. belt, which extends the length of the ore-bins and is provided with a tripper so adjusted that the ore may be discharged into any of the existing bins, or into the 10 new flat-bottomed bins, of a total capacity of

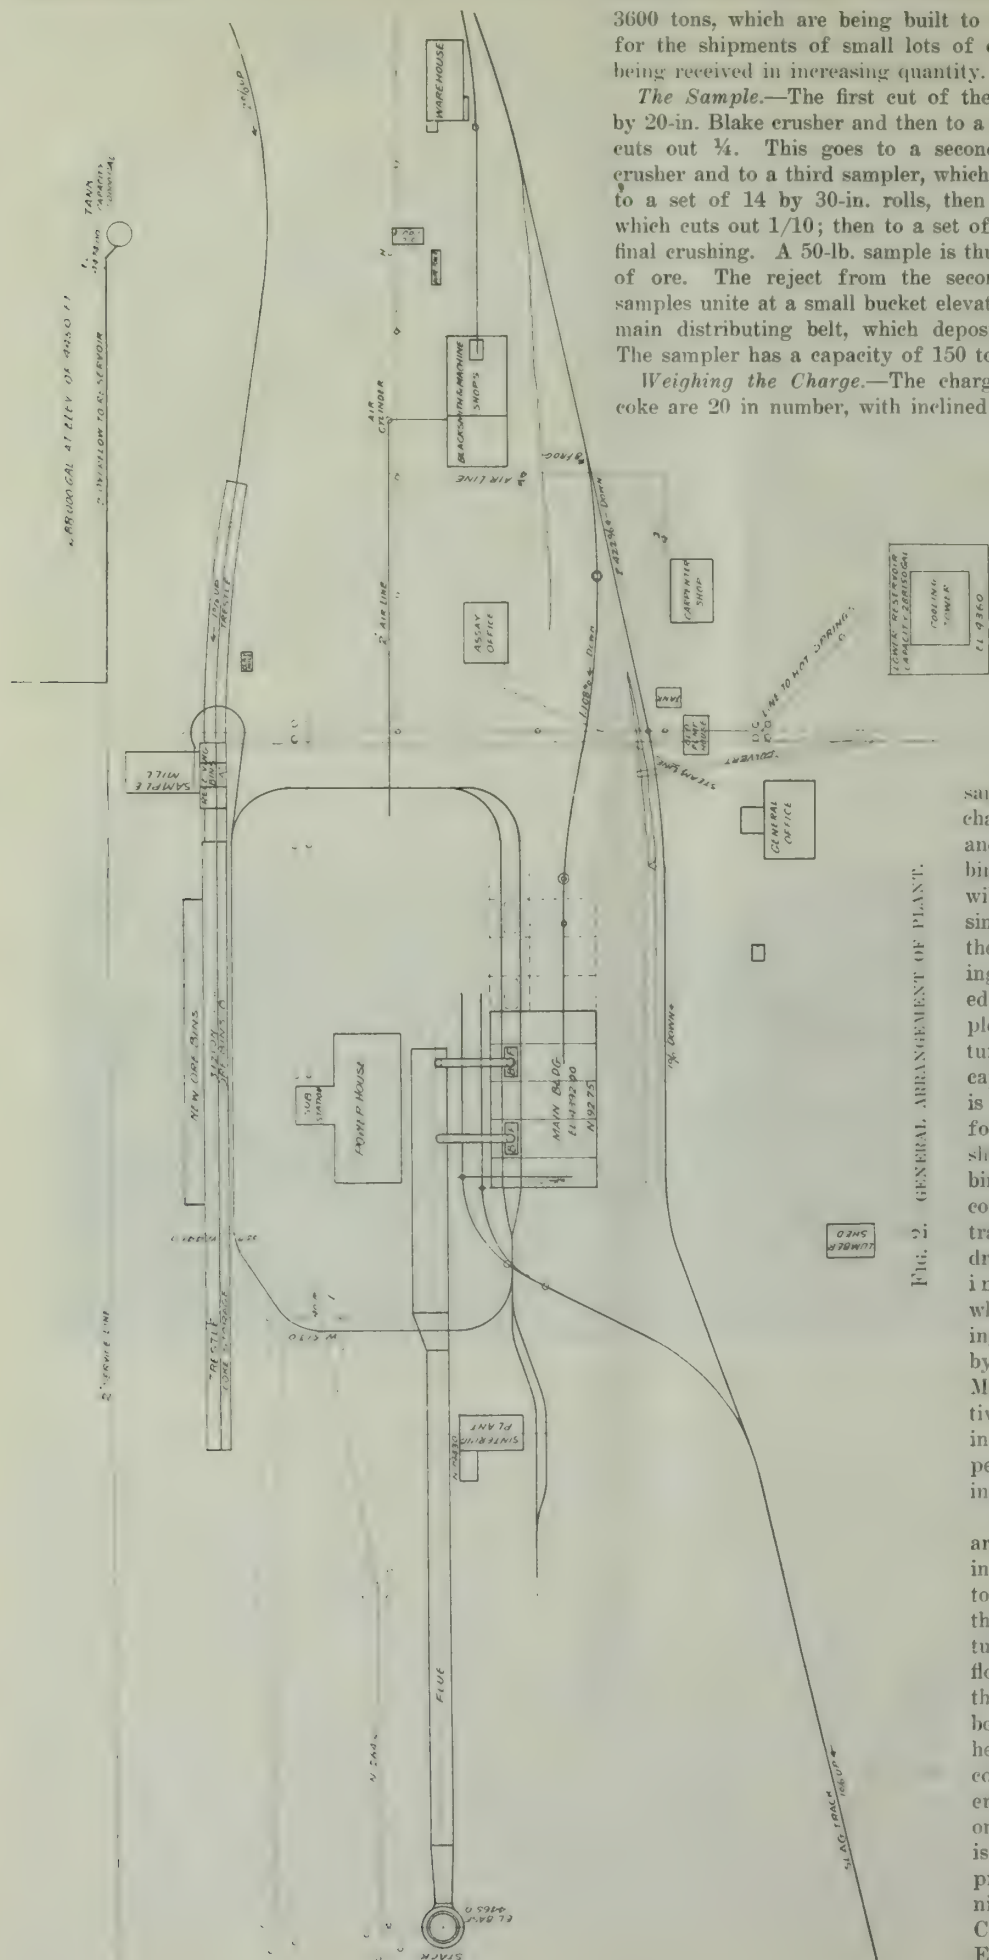

FIG. 2. GENERAL ARRANGEMENT OF PLANT.

3600 tons, which are being built to serve as bedding bins for the shipments of small lots of custom ore, which are being received in increasing quantity.

**The Sample.**—The first cut of the sample goes to a 10 by 20-in. Blake crusher and then to a second sampler, which cuts out  $\frac{1}{4}$ . This goes to a second 10 by 20-in. Blake crusher and to a third sampler, which cuts out  $\frac{1}{5}$ ; this goes to a set of 14 by 30-in. rolls, then to a fourth sampler, which cuts out  $\frac{1}{10}$ ; then to a set of 14 by 30-in. rolls for final crushing. A 50-lb. sample is thus obtained from a car of ore. The reject from the second, third, and fourth samples unite at a small bucket elevator and is raised to the main distributing belt, which deposits it in the ore-bins. The sampler has a capacity of 150 tons per hour.

**Weighing the Charge.**—The charging bins for ore and coke are 20 in number, with inclined bottoms and having a

total capacity of 4000 tons. Each is provided with two discharge gates and two Howe weighing-hopper scales. The ore from the bedding bins will be drawn out upon a belt beneath them and delivered to the main elevator in the

sampling mill, then discharged to a belt-conveyor and thence to charge-bins. Weighing the charge will thus be somewhat simplified, duplication of the equipment of weighing hoppers will be avoided, and an accurate sample of the bedded mixture will be obtained. The capacity of the sampler is amply large to perform this added duty. As shown in the plan, the bins and furnaces are connected by an elliptical track, and the charge is drawn from the hoppers into two-ton cars, of which six or seven, making up a train, are drawn by a four-ton Jeffrey MB-24 electric locomotive. These are shown in place beneath the hoppers in the accompanying illustration.

**Blast-Furnaces.**—There are two blast-furnaces, 42 in. by 25 ft. at the bottom, and 47 in. wide at the tuyeres. From the tuyeres to the charge-floor level is 15 ft., but the charge is kept 3 ft. below this, making the height of the smelting column 12 ft. The tuyeres are 4 in. diam., 25 on each side. The blast is admitted at 42-oz. pressure, and is furnished by two No. 11 Connelville blowers. Each blower is driven

by two 200-hp. A. C. motors, and is capable of furnishing 30,000 cu. ft. of free air per minute. Only one furnace is now in use; this furnace during the month of May smelted an average of 720 tons of ore and 80 tons of seconds and limestone per day. This corresponds to a smelting rate of 12 lb. per square foot per minute, considering the hearth area as the area at the tuyere level. Remembering that this is attained by the use of 9 to 10% of coke on the charge, the smelting rate here attained is the fastest of which I have any knowledge. High smelting speed has been attained in pyrite smelting, but in that case the bulky coke

the pots a small pot pivoted on a jib-crane is swung under the slag spout while the full pot is being pushed out, and the empty one drawn into its place. The contents of the small pot are then emptied into the large one. The slag pot is pushed to the dump, and dumped by electric motor controlled by motorman in cab of locomotive; the skulls being sufficiently free of matte so that no attempt is made to remelt them. The motorman of the slag car also performs a similar service on the locomotive which draws the train of matte-cars, and operates the crane, without being overtaxed. The track on the dump is shifted from

FIG. 3. BLAST-FURNACE, DUST-CHAMBER, AND STACK.

FIG. 4. WEIGHING-HOPPERS AND CHARGE-TRAIN.

is not present to displace a much greater weight of smelting mixture. For a low sulphur, high-coke charge this must be either a record smelting rate, or very close to it, but I shall be glad to be corrected if I am in error in making this assumption. The rapid rate of smelting makes necessary the use of an increased amount of jacket-water, as might be expected.

**Charging the Furnace.**—The furnace is charged directly from the cars. Adjustable feed plates, as shown in Figure 5, are provided, the angle of their inclination being capable of adjustment within the range 30 to 60°. By a little experiment the proper degree of inclination was found so that coke automatically falls in the position which gives the maximum smelting rate. After this was obtained it was found that the necessity for barring down crusts and punching tuyeres had almost totally disappeared. This, of course, contributes to the rapid smelting rate of the furnace. The operation of dropping a charge is quick and simple. A charge train usually consists of two cars of coke and four or five cars of ore. The furnace feeder draws up the charge doors as the train approaches, and as each car of coke is dumped the motor draws it slowly the length of the furnace to distribute its contents evenly. One car of ore is next dumped, and the other cars are then in position so that they may be at once dumped into the furnace. The operation of charging takes but 1½ to 1¾ minutes, and a round trip, loading and dumping the charging train takes but five to eight minutes. The smelting charge contains about 4% copper and 6% sulphur. Coke forms 9 to 10% of the smelting mixture.

**Handling Slag.**—The water runs continuously through a tapping jacket of cast iron with pipe coil cast in. The spout is jacketed, the inner sheet being sheet copper. It is customary in many places to cast the spout from blister, but as only matte is made at this plant, sheet copper was employed and gives good satisfaction. The slag and matte go to two 5 by 12-ft. movable settlers. These were employed, as it was feared that trouble would be experienced from the formation of sows. The expected trouble did not materialize, and it is now planned to replace these by a stationary 8 by 18-ft. settler. The slag flows from the second settler into a 225 cu. ft. (21 ton) capacity steel slag pot, hauled by a 15-ton electric locomotive. In changing

time to time, as required, by a gang of surface laborers, and the only persons regularly employed in dealing with the slag are the tapper and the motorman, the latter giving only a part of his time to it. The average composition of the slag is:

SO <sub>2</sub>	FeO	CaO	Al <sub>2</sub> O <sub>3</sub>	MgO	Cu
42	26.8	22	7.3	1	0.38%

**Handling Matte.**—About 50 tons of 45% matte is made in a day, and it is necessary with the present settlers to tap at intervals of ½ to ¾ hour. The second settler is only

FIG. 5. CHARGING DEVICE.

tapped once each shift, yielding a few hundred pounds of matte. The method of handling this is the only instance in which any important change has been made in the original design of the plant. Three Kilker matte-cars, operating on a circular track were placed in the plant. The particular cars employed proved too small for this situation and are not now used. The method now employed is similar to that formerly used at the United States plant at Bingham Junction, Utah, except that the wire rope there employed for moving the train of matte-cars is replaced by a 4-ton electric locomotive. The matte molds are carried on light steel cars; the molds are of cast steel

and have shown no sign of cracking. Each mold holds about 100 lb. of matte; and resembles a waffle-iron in pattern. The train will accommodate 50 molds; about 40 are in use. When the matte is tapped these are drawn back and forth below the matte-spout until all are completely filled. The operation of tapping takes 7 to 8 minutes. Then the cakes of matte are allowed to cool down to the point where it is safe to play a hose upon them, and are dumped into an ordinary 5-ton matte-pot, placed below the track. The cake in falling breaks up into eighty roughly cubical pieces weighing  $12\frac{1}{2}$  lb. each. The pot is dumped into a 50-ton railroad car, for shipment to the Garfield smelter. This handling is done by an ordinary 20-ton crane, with a 5-ton auxiliary. A certain amount of matte unavoidably spatters about; as this is cleaned up it is loaded into small dump cars which are hoisted by the crane to the charging floor. The building enclosing the blast-furnaces has been made large enough to contain converters, which will be erected when the daily output of matte reaches a tonnage large enough to permit reasonably continuous operation of a converter. The crane has been provided for this purpose, so the only construction necessary will be the addition of stands, shells, and blowing engine.

**Flues and Flue-dust.**—The downcomers from the blast-furnace enter the brick expansion chamber, which has a cross-sectional area of 500 sq. ft., and is 200 ft. long. The flue beyond this point is 18 by 10 ft. and ascends the hill-side to the base of the stack at a point 40 ft. above the furnace level. The stack is 200 ft. high, 18 ft. diam. at the base, and 15 ft. at the top. On the side of the expansion chamber next the furnaces automatic discharge gates for the flue-dust are provided which permit it to escape to an automatic dust-conveyor that conveys the dust to the Dwight-Lloyd sintering machine. This is so placed that dust can be drawn by the conveyor from 50 ft. of the flue as well. It was planned to mix the flue-dust with fine raw sulphides before sintering, but delivery of the machine was delayed and the blast-furnace had been in operation for three months before the sintering machine was started. The flue-dust had thus accumulated to a point where it was necessary to handle it as rapidly as possible. The attempt was therefore made to sinter the dust without the admixture of any raw sulphides, and after a little experiment success was attained. The necessary heat is supplied by mixing with the dust  $\frac{1}{2}$  to 2% of coke-dust, prepared by grinding coke breeze in a clay-mill. Sufficient water is added to give a mixture containing 8% moisture, and since the aim is to secure the maximum sintering with the minimum of desulphurization the machine is run rapidly, treating 60 tons per day. The speed of travel of the pallets varies from 1 to 5 ft. per minute. Some trouble has been experienced from the tendency of the cast-iron grates to crack, and it is planned to use malleable iron for the grates of the second unit, now under construction. The work of this sintering machine is of great interest, since it is the first instance of its use to treat flue-dust, unmixed with raw sulphides.

**Fuel.**—The coke used in the blast-furnaces is that of the Utah Fuel Co. The coke has 7% ash, and is somewhat stringy, but is a good burden carrier, and as it has to stand but little handling, it arrives at the smelter in good condition and works well. There is no steam plant at the smelter, all machinery being motor-driven, so there is no occasion for the use of fuel other than coke, beyond a small amount of coal in the blacksmith shop.

**Water Supply.**—There are two sources of water supply. Near the wagon-road between Wabuska and the smelter, a hot spring was first developed. This yields 40 gal. per minute at a temperature of  $170^{\circ}$  F.; the water is excellent and it was formerly cooled and used for domestic purposes. Later a well was put down at a point south of the smelter, about half way between it and the line of the Southern Pacific, and 90 ft. below the smelting level. This is a flowing well, 600 ft. deep, yielding 120 gal. per minute; another adjacent well yields 30 gal. per minute more, so an ample supply is available. The jacket water is cooled in a cooling-

tower just below the general offices, to avoid the necessity of the 90-ft. lift on water than can be re-used.

**Power Supply.**—Electric power for the operation of the plant is purchased from the Truckee River General Electric Co. The current mainly comes from the new plant at Verdi, but there is another line connecting through Mason with the older line, so that the smelter has two independent supply-lines, and can draw current from any one of four power plants. Current is received at 60,000 volts, and is transformed to 440 or 220 volts for the A. C. motors. The cost of electric power is \$70 per horse-power year.

**Ore Supply.**—The ore supply of the plant is rapidly increasing, as the low treatment rates accorded have served to stimulate a number of small shippers who are largely engaged in development work, while both the Nevada-Douglas and Mason Valley mines are prepared to increase their shipments; it is especially desirable to increase the tonnage of Mason Valley ore treated, as it is slightly basic, and if used in sufficient amounts the necessity for limestone flux is removed. Accordingly the No. 2 furnace, which has not yet been blown in, is being increased to 30 ft. in length; when it is ready to operate the No. 1 furnace will be blown out and increased to 35 ft. in length.

It is a pleasure to a smelterman to watch a furnace operate so smoothly as this one does, without the constant necessity for barring down crusts. This is partly due to the good smelting mixture, perhaps partly due to that more or less fortuitous harmony of parts which makes one 6-cylinder motor car a much better hill-climber than another of identical pattern and make, but is largely due to its excellent design and management.

## New Topographic Maps of the U. S. Geological Survey

Topographic maps of the quadrangles named below are now ready for distribution.

Beverly, Washington, embracing parts of Grant and Kittitas counties. Ivanpah, California-Nevada, embracing parts of Inyo and San Bernardino counties, California, and Clark County, Nevada. Laurelville, Ohio, embracing parts of Hocking, Pickaway, and Vinton counties. McCall's Ferry, Pennsylvania, embracing parts of Lancaster and York counties. McKeever, New York, embracing parts of Herkimer, Lewis, and Oneida counties. McKittrick, California, embracing parts of Kern, San Luis Obispo, and Santa Barbara counties. New Berlin, New York, embracing parts of Chenango, Madison, and Otsego counties. Newhard, California, embracing parts of Butte and Glenn counties. Quarryville, Pennsylvania, embracing parts of Chester and Lancaster counties. Thibedean Lake, Montana, in Chouteau county. Welch, West Virginia, embracing parts of McDowell and Wyoming counties.

The following sheets have been issued in a preliminary edition, each sheet showing only a portion of the quadrangle. This edition is limited to a few copies, which will be sold at the same price as the regular atlas sheets:

Keefers, California, in Butte county. Naugatuck, West Virginia, embracing parts of Mingo, Lincoln, and Wayne counties. Oroville, California, in Butte county. Pounding Mill, West Virginia, in McDowell county. Singer Creek, California, embracing parts of Butte and Tehama counties.

TEXAS production of gold, silver, copper, and lead in 1911, according to Charles W. Henderson, of the U. S. Geological Survey, showed an increase, compared with the yield in 1910, of \$11,415. The output of silver, which represents over 97% of the state yield, was 424,394 oz., valued at \$214,929, an increase of 44,072 oz. in quantity and \$9555 in value. The yield of lead was 122,800 lb., compared with 65,068 lb. in 1910. The yields of gold and copper, both nominal, showed decreases for 1911. The greater part of the output was from the Shafter district, Presidio county.

# Government Policy and Coal Lands

By WALTER L. FISHER

\*You may not have noticed a recent sale of government coal lands in your state which was made in the Evanston land office on June 3 last. Six hundred and sixty-five acres in this section, which lies a short distance north of Rock Springs, were sold by the government at prices ranging from \$370 to \$410 per acre, the aggregate sum received for the section being \$263,330. This sale is significant as illustrating the practical effectiveness of the present policy in the administration of the coal-land law. The fact that this large acreage, the maximum that can legally be acquired under existing law, has been sold at these prices which represent nearly the highest valuation that has been placed by the Department upon any of the public coal lands, indicates that the policy of selling these lands at appraised prices, based upon the quantity and quality as well as the accessibility of the coal, is a practical businesslike policy.

The charges that you have so often heard, and indeed have repeated to me, to the effect that the valuation of these coal lands by the government geologists is academic, and that the prices thus established are so excessively high as to defeat the purposes of development and paralyze the coal industry of the Rocky Mountain states, is directly and effectively answered by this action on the part of several of your Wyoming fellow-citizens. These practical men have had this purchase under consideration for some time, and have doubtless thoroughly acquainted themselves with the inherent value of these lands. Probably their estimates were based largely upon the same information that was available to the geologists who made the field examination on which the government valuation was based.

This sale illustrates well certain phases of the general public-land policy of today. As you know, it is the purpose of this administration to encourage present-day development of the resources of the West, so far as that is attainable under existing law, and at the same time to protect future utilization from the ill effects of present-day speculative and industrial waste. The purpose in placing moderate valuation upon the millions of acres of coal land still in public ownership is to make the prices at which these lands are offered low enough to encourage their acquisition for immediate development, but high enough to prevent purchase with no idea of immediate use. It is evident that the Wyoming business-men who have acquired this section of coal land expect soon to begin to realize on their large investment, an end that can be attained only by an early beginning of mining operations. Thus one purpose of the public policy is fulfilled. Again, it will be noted that the amount received for this land in excess over the minimum price allowed by law is almost exactly a quarter of a million dollars, so it follows that the administration of this policy has resulted in the contribution of a quarter of a million dollars to the Reclamation Fund, which amount is immediately available for the development of the irrigable lands in the Western states.

Nor can it be contended that the sale of these coal lands at this high price constitutes a tax upon the consumer of Wyoming coal. The several coal beds underlying this tract of land together include so great a thickness of coal, and the tonnage therefore available for mining is so large, that in so far as this coal is immediately mined the highest acre-price on this tract, when translated into price per ton of minable coal, is considerably less than one-half cent a ton. The result is that even were the Wyoming citizen to buy an amount equivalent to

the average per capita consumption for the whole country—which includes of course not only coal burned in homes, but that consumed by the railroads and any other generators of power—he would suffer an annual per capita tax of less than two cents.

All that this increased government price can do is to eliminate a portion of the unearned profits of the speculative middleman. The price realized by the government for these lands is a very moderate fraction of their value. Had the present purchaser secured them at the old price of \$20 instead of at \$400 per acre, he would still have sold them or the coal from them at a market value determined, not by the fact that earlier grantees secured government coal lands for \$20 per acre or for nothing, but by the fact that private or corporate holders of these lands can and do secure from them returns that justify that market value. That this value is in excess of \$400 per acre is proved by the recent sale. The present purchaser of the tract, therefore, as a result of the modern policy, has contributed to the public funds for use in the reclamation of the West a quarter of a million dollars, which under the old policy would have been added to his profits without being earned and with no public benefit. It seems to me indisputable, therefore, that this gain to the citizens of the public-land states by reason of this policy is tangible and direct, and that any loss that they may suffer is theoretical, inappreciable, and probably nonexistent.

I think you will agree with me that stability through the elimination, or at least the reduction, of the speculative element is desirable in any industry. So long as coal can be acquired only by purchase, not of the actual tonnage mined as under a leasing system, but of some estimated amount present beneath a given acreage, as under the present system, there will be a large speculative element at the very foundation of the coal business. Therefore, while the present plan of selling coal lands at values based on careful estimates of the quantity present is a great advance over the earlier practice of selling at a low flat rate wholly without consideration of either the quantity or the quality of the mineral present, neither method is the equal in fairness to the operator or to the consumer of that adopted in principle by your own state of Wyoming, a method which I have frequently publicly advocated as a policy that should be adopted by the Federal Government in the management of its coal lands. I refer of course to the leasing system. Under that system the coal operator buys and pays for the actual amount of coal that he mines. Under the present purchase plan he does not know absolutely what he is receiving, and in the absence of this exact knowledge he will, as a conservative business-man, base his selling prices upon the most adverse supposition. The consumer must pay these prices and must suffer accordingly. These elements of uncertainty would be eliminated under a federal leasing system, so that the speculative charge would disappear. With it would go the legitimate interest charge upon the purchase price, which may become of considerable importance in the case of the heavy investments required by large coal operators who buy reserves in anticipation of future needs and pay middlemen's profits because under present statutory limitations inserted to protect public interests by restrictions to prevent monopoly they are unable to buy large tracts direct from the government. No interest accrues against lands held by the government, so that no interest charge enters into the price at which the government sells its coal under either the leasing or the sales system. Nevertheless, because the government geologist, when estimating the reserves for purposes of sale, resolve every doubt in favor of the purchaser, in the great majority of cases he probably acquires tonnage several times greater than

\*From a letter by the Secretary of the Interior to F. W. Mondell, of the House Committee on Public Lands, Washington, D. C.

that for which he pays. For this reason and because a higher tonnage charge can properly be made under the leasing system, the returns to the government would be much larger under it without a corresponding increase of hardship or cost to the producer, since the hazards which he must capitalize and the interest charges which he must pay are eliminated in that system.

The Rock Springs field is one which has been largely developed and thoroughly prospected, so that closer estimates of tonnage can be made there than in most fields, and a fairer comparison of returns from the leasing and the sales system is possible. The geologists who classified this field believe that the section recently sold contains at least 136,000,000 tons of coal. Assume that one-half of this amount can be economically recovered in mining and that the low royalty of two cents per ton is charged. The returns to the government on this basis compared with those from the recent cash sale and with those under the old flat-rate plan, for the 665 acres recently sold, are as follows:

Sale price at \$20 per acre.....	\$ 13,300
Sale price tonnage basis.....	263,330
Returns leasing basis at \$0.02 per ton.....	1,360,000

Such practical considerations and examples as this carry their own lesson. It is clearly evident that the present coal-land policy is from every point of view superior to the old and that it is a practical working policy. It is equally clear to me that a leasing policy is as much superior to the present plan as that is to the old. I have been glad to note that your own state has had the wisdom to adopt the general policy of leasing. As a loyal Wyoming citizen believing in the policies of his own state, and as a Western man desirous of fostering the healthy development of the West and of advocating means to that end, you, I am sure, will be interested in the transaction which is the occasion for this letter.

## Cyanogen Compounds From Distillation of Coal

\*In the distillation of gas from coal, nitrogen appears combined in the by-products in many different forms. Among them, it is found in the gas, the tar, the ammoniacal liquor, and, after the gas is purified, in the purifying material combined with carbon to form cyanogen and cyanogen compounds, such as the ammonium salts, the thiocyanates, and others. There have been many methods of cyanide recovery devised. Among them is the Bueb process used to some extent in this country. It consists briefly in scrubbing the gas, before the ammonia and sulphur are removed, with a solution of copperas, whereby ammonium sulphate, which remains in solution, and ferrous sulphide, which remains in suspension, are produced. The hydrogen cyanide and free ammonia in the gas now react with the ferrous sulphide, giving ammonium ferrous ferrocyanide of the formula  $(\text{NH}_4)_2\text{Fe} \cdot \text{Fe}(\text{CN})_6$ . Some of this double ferrocyanide may be converted into soluble ammonium ferrocyanide by the reagents present, and to prevent this the 'mud' is either boiled or made slightly acid with sulphuric acid. In either case the insoluble double ferrocyanide is formed, and the mud changes color almost from black to light yellow. The final products are an insoluble double ferrocyanide, and a solution of ammonium sulphate. These are separated from each other by filtration. The process has been found to work best at temperatures not exceeding 100°F. Under these conditions, 90 to 100% of the total cyanogen is extracted. On a yield of 1.75 lb. of cyanogen per ton of coal carbonized, equivalent to about 110 grains of cyanogen per 100 cu. ft. of gas, the amount of copper

as required theoretically is 6.3 lb., and the amount varies little from this in practice.

The absorption of cyanogen by the Bueb method generally takes place in a standard washer. The gas should reach the washer freed from tar, and at a temperature not over 100°F. The solution of ferrous sulphate is run into the outlet end of the washer, where it is first converted into ferrous sulphide and ammonium sulphate. There is a tendency for the former to build up on the exposed surface. In the original method of operating the washers, the material was pumped from tray to tray, whenever the first tray was saturated. This involved a deal of pumping, so operating the washers on the principle of an ammonia washer simplified the work. The material in the inlet tray is tested from time to time. In Germany the mud from the washers is generally sold to chemical works, while at the Astoria plant of the Consolidated Gas Co. of New York it is pumped into lead-lined tanks, heated to about 200°F., and acidified with sulphuric acid. Just enough acid is used so that the mineral is slightly acid to litmus.

The mud is tested for soluble ferrocyanide with ferric chloride solution on a piece of white filter-paper; and if the blue color appears, ferrous sulphate solution is added a little at a time, until upon test the blue color no longer appears. This converts all the cyanogen into an insoluble form. The mud now consists of insoluble double ferrocyanide of ammonia and iron, and a solution of ammonium sulphate, with a little ferrous sulphate, and very little free acid. This is pumped into filter-presses, which, when full, have hot water pumped through in order to wash as much as possible of the ammonium sulphate. The best results are obtained by finishing the pressing with mud made by stirring up some of the finished press-cake with water, until it disintegrates. The presses are about two-thirds filled with the neutralized mud from the washers, and then finished with the mud made from final cake. The solution of ammonium sulphate from the presses is neutralized with ammonia, settled, and the clear solution evaporated in lead-lined pans. It contains about one pound of ammonium sulphate per gallon.

The cyanogen cake from the filter-presses contains approximately 40 to 50% water, 22 to 28% cyanogen, and 5.3 to 7% of ammonia, about 6 lb. of press-cake being produced per ton of coal carbonized. About 2.5 to 3 lb. of ammonium sulphate is produced per ton also. The press-cake is sold to chemical works to be converted into sodium or potassium ferrocyanide. This is done by first distilling with lime, which drives off ammonia, and forms calcium ferrocyanide. This solution is filtered from the residue of iron hydrate, and is then treated with sodium or potassium carbonate, forming the corresponding ferrocyanide, and calcium carbonate, which settles out. The clear solution is concentrated and the ferrocyanide crystallized.

DIAMOND-BEARING lands in Bahia, Brazil, are state property; the person who wishes to dig may either rent a claim for his exclusive use or take out a miner's license at a small cost and dig on unoccupied land or in non-leased river beds, concessions of which are readily granted by government. The outlook for a well-managed concern entering the most attractive part of the industry, namely, the working of the carbonado, or black diamond, deposits, is said to be distinctly promising. Good carbons—and 90% of the stones found are good—sell when over  $\frac{3}{4}$  carat at about \$5 per carat. Bahia diamonds of good color and shape are sold by the miners at about \$11.25 per carat; small stones of good quality and color fetch about \$10.50. Only a small proportion of the diamantiferous alluvium has been explored, and the river gravels, except in shallow reaches, are untouched. Moreover, these gravels are reputed often to carry enough gold to pay for dredging.

\*Abstracted from 'By-Products in Gas Manufacture,' a lecture delivered by C. E. Munroe at the centenary celebration of the first commercial gas company held at Franklin Institute, Philadelphia, April 18, 1912.

The mines producing zinc in New Mexico in 1911 are at Kelly, Socorro county, and in Pinos Altos and Central districts, Grant county. The yield decreased in both counties.

# The High Grade Mining District

By WILLIAM H. STORMS

High Grade mining district, which has the past few months attracted considerable attention from prospectors, and investors as well, is situated in Modoc county, California, and extends a short distance northward across the state line into Oregon. It is on the summit of the Warner range of mountains which lies between Goose lake, on the west, and Surprise valley on the east. The entire district is in a region of volcanic rock—andesitic and rhyolitic flows and tuffs, forming the central portion of the range with later flows of basalt and agglomerate on the eastern borders.

The history of the district extends back for many years, but the entries are few. At one time the Government maintained a military post in Surprise valley, known as Camp Bidwell. This place, now called Fort Bidwell, is about twelve miles southeast from High Grade, and is near the eastern base of the Warner mountains. Soldiers from the fort, and others, found gold in the Warner range many years ago, but the principal prospector was a man named Hoag. He did considerable work at the surface on various claims, and the district came to be known by his name. In 1905 new discoveries in these mountains resulted in renewed interest in the possibilities of the region, and then, for the first time, some real development was accomplished, which has since been followed by a much more general interest in these prospects and the re-naming of the district, it being now known as High Grade. It is needless to say that this newest name for an old district was suggested by commercial considerations. Nevertheless, there is high-grade ore in several mines of the district.

The geology of the district is comparatively simple when viewed in its broader features, but somewhat complicated here and there locally. The Warner mountains consist of a thick series of volcanic flows and sediments which form a portion of the great volcanic plateau which covers all of Modoc county, a large part of Shasta and Lassen counties, and extends northerly and easterly into Oregon and Nevada. The general history of the Warner range, as indicated by exposures in that region, shows that a vast mass of nearly horizontal volcanic strata, chiefly andesites, rhyolites, and tuffs, were cut by a great fault which skirts the east shore of Goose lake. In fact, it looks as though Goose lake were the direct result of the faulting of this region. Israel C. Russel has written a most interesting description of a number of these faults which occur in southeast Oregon and extend southward into California. Several of the valleys formed by the faulting of the great volcanic plateau are the sites of lakes; others have been filled with detritus and are now fertile valleys. Along the east side of the Goose lake fault the volcanic beds were lifted 2000 ft. or more, the entire series dipping 10 to 20° to the eastward. Russel describes a similar fault along the eastern base of the Warner range in Paradise valley, so the Warner mountains as a whole represents a great fault block, lifted above the surrounding valleys, the strata having a general dip to the eastward. In the central portion of this range the rocks do not all lie so nearly flat, but are found more or less disturbed, at some places standing in vertical position. There are in the central area several minor faults which have divided the district into a number of fault blocks. It is in the vicinity of these faults that the principal mineralization has taken place, along zones of brecciation, or following fissures in the breccia, which strike in various directions, though usually north-south and east-west. Where these fissures have intersected each other there has, in some places, been an enrichment, and it is the occurrence of this

rich ore that doubtless suggested to the miners the name of the district—High Grade.

There is evidence to prove that after the uplift of the range and the formation of the brecciated zones and fissures in which the gold-bearing ores are now found, there was a long period of erosion, as the strata of rhyolites and tuffs are found planed off in some localities on the higher hills, and the gentle slopes to the northeastward, which at first might easily be mistaken for dip-slopes are really the result of erosion. The theory of a period of erosion at that time is proved by the fact that the later flows of basalt and andesite with their accompanying tuffs, overlie the adjacent hills to the eastward, tongues and remnants of the basalt being found lying on the older rhyolite and tuff, which would be impossible had the upper rhyolite not been removed by erosion. These later volcanic rocks have no connection whatever with the mineralization of the district, but it is interesting to know that the ore-bearing formations extend eastward and northward beneath the more recent

MAIN STREET, HIGH GRADE.

volcanics, as it admits the possibility of the extension of the known mineralized zone in that direction. I was shown some ore, a silicified brecciated rhyolite, from the east side of the Fort Bidwell range, that much resembled some of that found in the High Grade district. For lack of time I did not visit that locality. Since the period of basalt flows the entire region has been subjected to tremendous erosion, as indicated by canyons 3000 ft. deeper than the top of the basaltic plateau.

The accompanying sketch, Fig. 1, is a northeast-southwest cross-section of High Grade district, drawn through Yellow mountain, one of the highest points in the district. It will give a general idea of the structural geology of the district as a whole. The time at my disposal was not sufficient to admit of a critical examination of the entire region in detail, so at this time generalizations only can be submitted. The sketch map, Fig. 2, shows the drainage of the country, and on it are also indicated some of the faults which appear to have important bearing on the structural features of the district, and incidentally on the mineralization.

I did not ascertain the natural succession of all of the rocks in the undisturbed area lying in the western part of the Warner range, but know that these rocks are principally white flow-rhyolite and white rhyolite-tuff. These comprise the greater part of the front or west range. About half way between the base of the mountains, and High Grade camp, I believe the rocks have been faulted, and some of the rhyolite and tuff found in the front range appears to be repeated to the eastward of this fault, if it actually exists. This should be verified, as the fault-line

may be said to be suggested by topography rather than by actual evidence. However, about half a mile east of the electric-light plant on Pine creek, an abrupt facade of purplish rhyolite rises several hundred feet above the bottom of the canyon, with a steep talus at its base. Its course is a little west of north and east of south. Bluffs and knobs of what appeared to be the same rock may be seen for a distance of a mile and a half or more, occupying a similar position on adjacent hills, and in direct line with the main palisade on the north side of Pine creek. This I think to be, in all probability, the main cause of bringing the rhyolites of the front range once more to the surface in the vicinity of High Grade. If this fault actually occurred it must have a throw exceeding 2500 feet.

The principal rocks of the High Grade district are a white flow-rhyolite at the top, underlain by a bed of variable thickness of white rhyolite-tuff, usually buff colored near the surface, and this in turn is underlain by purple porphyritic rhyolite. These rocks extend from the extreme northerly end of the district, where they pass under the more recent basalt, to the south end, at the Sugar Pine and Mountain View mines of the Fort Bidwell Consolidated group. Southerly from there the rock is principally an ancient andesite of very fine texture, ranging from bluish-black to greenish-black and grayish-black in color. I did not see a single intrusive dike in this portion of the range, though dikes of basalt cutting the tuffs and rhyolites south of Cottonwood creek are numerous. These latter are five to six miles southwest of this district. In that vicinity, on and near the Snyder ranch, are also fissure veins containing gold, some of them being very encouraging prospects.

There are several types of ore deposit in High Grade district. The most common are zones of brecciation, highly silicified and auriferous. These occur in flow-rhyolite and tuff, and also in the earlier andesite at the south end of the district. A second type is that of rather small fissure veins

FIG. 1. CROSS-SECTION AT HIGH GRADE.

cutting at high angles through the zones of brecciation. In some of the mines these fissures run at nearly right angles. At the intersections rich ore has been found.

A third type occurs in the form of nearly flat sheets of rhyolite or tuff, highly silicified but with little or no brecciation, though auriferous. These may be considered as zones of impregnation. Still another type is the fissure vein occurring outside of any zone of extensive brecciation. This latter is represented in the North Star mine, where a fissure, varying in size from an inch or two to three feet or more, runs through the earlier andesite. Some of this rock contains payable ore; some of it is low grade. The quartz is white and saccharoidal, and shows some blue and green copper carbonate. This is said to be the discovery vein of the district. It is developed by several hundred feet of workings. It is at present held under lease and option.

The Sunset workings, consisting of about 800 ft. of development, are entirely in the earlier andesite, which here is found sheeted by pressure, the structure making it appear like a nearly vertical dike, or intrusion. I think that a fault of considerable displacement passes just east and south of this locality, its course being denoted by the neighboring canyons, Evening Star gulch and Sunset gulch. On the opposite side of this canyon and about 100 ft. south of the Sunshine mine, the basaltic strata of Mount Vida are seen to have a northwesterly dip, which is opposite to the general dip of the formations to the northward. This fact appears to lend color to the probable existence of the fault here referred to. This fault has a curving strike, the concave side facing the west. Unfortunately, at the sev-

eral points where these faults pass through low saddles, in every instance examined, the evidence of their existence is obscured by low flat surfaces, covered by deep soil, or piles of rock.

The Fort Bidwell Consolidated property comprises several claims. The Mountain View, one of these, occurs in a zone of breccia at the contact of the earlier andesite with the rhyolites, whereas the Sugar Pine, another of its properties, is wholly in the rhyolite.

The Shasta View, adjoining the Mountain View on the southwest, is wholly in the earlier andesite. Both of these properties have some high-grade ore, and much that is too low in value to ship, but which is still a good grade of milling ore.

The Fort Bidwell company is operating a 10-stamp mill. The ore is delivered to the mill from the Mountain View by drift and tramway on the mill-level, and from the Sugar Pine, which is on the opposite side of the divide, by aerial

FIG. 2. SKETCH MAP OF THE HIGH GRADE DISTRICT.

rope-way. The workings of these two claims are to be connected, when all ore can be sent to mill through the main adit, which will prove a great advantage, as the deep snow in winter interferes with the operation of the rope-way.

The Alturas company's property is on the east slope of Yellow mountain, and is wholly in the rhyolite. The principal shaft is 105 ft. deep. Hoisting is done with a horse-whim. In this shaft a shoot of ore in purple flow-rhyolite is being developed. This ore contains more sulphide (pyrite) than was observed in any other mine in the district. Yellow mountain slopes from its crest, at 10 to 15° eastward for a distance of a mile, when it plunges steeply downward into Evening Star gulch. Along the rim of this sudden descent, and on the flat back of it, are a number of promising prospects. Some of these belong to the Alturas company, others to the Seven Lakes company, while still others are held by the locators. Among these latter is the Dandy Fraction, which makes an encouraging surface showing. These workings are mostly in the brecciated flow-rhyolite, though a few are in the tuff. Some of them are of the impregnation type. On the northeast side of this rim considerable work has been done on a claim called the Mountain Sheep, but the mine is idle, due to pending litigation. The cause of the contention lies in the fact that the Mountain Sheep conflicts with three other locations, having been laid diagonally across them.

To the eastward of Yellow mountain and between it and Camp High Grade is the property of the Big Four company. The ore deposits here are of several types, including practically all of those found in the district. One of these

is that of a flat sheet of much silicified rhyolite which shows little evidence of brecciation. This ore is being treated in the company's 5-stamp mill, with good results, so I was informed. In this property considerable work has also been done on a nearly vertical fissure vein, in which high-grade ore was found.

The Sunshine, Yellow Jacket, and Last Dollar mines are on Sunshine hill and are practically in the camp of High Grade. The ore here occurs mostly in brecciated masses of rhyolite with north-south and east-west fissures cutting the zones of brecciation. It is at the intersection of these fissures that the rich ore has been found. The first shipment of 10 tons carried over \$250 per ton gross value. Another shipment was ready at the time of my visit. On the Sunshine hill there are at least three separate zones of brecciation, and there may be others not as yet developed. The Sunshine claim has been divided into a number of blocks, nearly all of which had been leased, and the lessees were eagerly working to develop their several holdings. To the eastward on a neighboring hill the Gold Shore claim resembles the Sunshine, having the same rhyolite breccia and silicification, which is an accompaniment of the auriferous ores of profitable grade everywhere in this district.

On the plateau north of High Grade is a group of claims owned by the Modoc Mines Co. A shaft had been sunk to a depth of 60 ft. at the time of my visit and some excellent ore found. The ore here is in the brecciated rhyolite. This company has built a substantial head-frame and has a well equipped steam-hoist.

There are numerous other claims scattered throughout the district, but which had so little development that no particular mention is made of them, though some of these show good prospects in gold. I observed fissures in various parts of the district, in which the rock was much kaolinized and stained by iron oxide, but all of the occurrences of this character that came to my attention were low in gold. There may be exceptions to this, but I did not see them, if there are any.

There are some striking features in the topography of this district, which are due principally to two causes, first, minor faulting, and second, climatic conditions. Naturally the first cause has left the more noticeable results as observed in the steep slopes on one side of the hills, which are probably fault scarps modified by erosion. There is undoubted evidence of the former presence of small glaciers, as indicated by the kames, moraines, small lakes, and swamp holes, in the canyons of the region. Cave lake, Lilly lake, Opal lake, and others are all of this origin. Since the glacial period erosion has progressed so far as to destroy practically all evidence of its former existence except the features above described.

Another pronounced feature in the topography is in the so-called 'rock piles.' These are generally the locus of ore disposition. All the ore of the camp, so far as I observed, is extremely silicious. The already dense rhyolites, in the zones of fracture and brecciation, have been rendered additionally hard by the infiltration of silica, and these zones being more resistant to erosion have a tendency to stand up in wall-like masses above the surface. These walls have been attacked by alternations of freezing and thawing, and the result is, as seen, a breaking down of these hard outcrops and the scattering of the fragments, large and small, over a considerable area in the immediate vicinity of each occurrence. This has made the development of the ore-bodies rather backward, as so much superficial work was required, and is still being done to find the gold-bearing rock in place. The prospector first finds 'float' ore in the pile of loose boulders. He then decides, as well as he can, upon the most likely point to find the orebody in place. The loose rock is often from 10 to 30 ft. in thickness and it requires considerable preliminary work to reach solid rock. In most places an adit run from some place on the mountain side would best solve the problem, but these lessees want to find their ore and stay with it, which from their point of view, is good policy. Owing to these peculiarities, the hardness of the rock, shortness of the summer season,

and lack of present liberal financial aid, it will probably be another year before much more is known of the geological conditions obtaining in this district, than is indicated in this description, for the work of development will proceed slowly at first.

The metallurgical problem is not a difficult one. At present, simple amalgamation is the only treatment given these ores, but the percentage of value thus saved is sometimes discouraging. The gold is extremely fine in most of the ore, though the richest ores occasionally contain much visible gold. I believe that the cyanide process will satisfactorily solve the metallurgical difficulties. The only sulphide observed was pyrite, with a single exception, which was an occurrence of mispickel. Copper also occurs in a few places, but in small amount. Generally speaking, so far as developed, iron sulphide is far from abundant in these mines, the gold appearing to be associated rather with the secondary silica than with sulphides of the base metals. Most of the gold is accompanied by silver, some of the bullion running as low as \$12 per ounce. Most of the ore affords excellent examples of that condition so interestingly described by Franz Posepny as 'crustification.'

The district is an ideal summer camp. It has the advantage of abundant timber and water, and is but 9 miles from the railroad, at New Pine Creek. Deep creek, which heads just north of High Grade will furnish abundant power which can be transmitted into the district. So, on the whole, High Grade may be said to possess the elements of success. The energetic men who are at present interested in the district, and who, by the way, are mostly from Colorado, where they do not look upon the deep snow of winter as an insurmountable obstacle, will, without doubt, make the most of the situation at High Grade and achieve the success to which they are entitled. At present there are no saloons in High Grade, and little or no gambling, nor is there either church or school, but the people of the camp are optimistic to a degree, and most of them have calloused hands, which speaks much for their faith. A portion of the district—that at the north end, is on 'school land,' section 36, which was purchased from the state. The rest of it is in the forest reserve.

It has been repeatedly stated by some of those interested, that High Grade district is "another Cripple Creek," and that it will "eclipse Goldfield." These and similar comparisons with noted mining districts have been made. Geologically it bears no resemblance to either Cripple Creek or Goldfield. The mineral deposits are only in a remote way similar to those of Goldfield, and very unlike those of Cripple Creek. Each mining district must stand or fall upon its own intrinsic merit. High Grade will, without doubt, produce some profitable mines, but how many remains to be determined by development and ore treatment. Already the newspapers are beginning to contain statements attributed to me, which I never uttered. The above description of the camp is a truthful one, and presents the district to the mining world as I saw it during my visit of a few days. The work was a reconnaissance at best, and the statements made are subject to change as development proceeds and the district becomes better known.

That every claim, or group of claims, in High Grade district will become profitable, I do not believe, but the superficial showing certainly justifies energetic prospecting, and that, too, in some places where little has as yet been done. There is a probability that the development of the surrounding country will extend southward, to Mount Vida and beyond, and some encouragement has already been given prospectors in that direction. I did not visit that locality, however, and know of it only from the description of those interested there, who showed me some ore which they said came from that locality.

STORES valued at \$58,250,000 were purchased during 1911 by Rand gold mines.

SILVER produced from Transvaal gold mines amounted to 894,833 ounces.

## Edison Giant Crushing Rolls

By J. F. SPRINGER

The annual production of open-hearth steel in the United States equals that of bessemer. It is confidently expected that the near future will disclose still more favorable results. Whatever has to do with economy in this process will be of interest to those who are concerned in steel manufacture. It so happens that the character of the limestone plays an important part, and the quality of the open-hearth steel or the economy of the production of lime rock of high quality depends largely upon the freedom of the limestone from silica. The cost of production turns largely upon the price per ton of a very pure limestone delivered at the furnace. If a considerable railway haul is involved, then economies will have to be sought in the processes of mining or quarrying, of crushing, screening, and loading.

In the Martinsburg district of West Virginia are large deposits of fine limestone which outcrop on the surface. A great deal of rock is steeply tilted, so that the mining operations consist largely in the removal of the overlying soil or useless rock and a breaking of the limestone by blasting operations. The property of the National Limestone Co. consists of about 1000 acres upon which are four deposits. The one which is now being worked is two miles long and upward of 150 ft. deep. Its width averages about 200 or 250 ft. The stripping preparatory to quarrying of the limestone is a simple operation, consisting merely in the removal by hand methods of a thin layer of soil. The strata stands almost vertical. The edges are much eroded and soon become whitened upon exposure; so that a stripped area presents an appearance not unlike a mass of monster bones. The irregularity of the upper face of the limestone thus precludes the use of machines in stripping. The mining consists in throwing down parts of an approximately vertical wall, by drilling vertical holes back from the face and blasting. The ordinary churn-drill is employed, a gasoline engine supplying the power. The entire drill-rod, including the bit, will weigh about 1100 lb. The hole made is 6 in. diam. A row of 6-in. holes is put down 25 ft., back of the face of the quarry, and at intervals of about 20 ft. to a depth of perhaps 160 ft. The blasting is accomplished in two operations. First, about 75 lb. of 50% dynamite is exploded at the bottom of the hole to create a cavity. About 1000 lb. of dynamite is then loaded, filling the cavity and reaching up into the undamaged part of the hole. The bottom half of the dynamite is 50% strength, and the upper half 30%. When this charge is exploded, the lower portion of the wall is thrown out upon the floor of the quarry and the shattered but not displaced upper rock settles down into the position formerly occupied by the lower portion. This system of blasting can be used to advantage wherever a vertical wall is to be thrown down. It is of especial advantage at Martinsburg because of the fact that the strata are highly tilted. The foregoing details as to depths and positions of holes and sizes and strength of charges are typical.

At Martinsburg a 100-ton steam-shovel is employed to handle the product of the blasting and to load it upon special skip-cars. Steel skips are also employed. A stone which is not too large for the shovel is not too large for the crushing apparatus. Secondary blasting of particular blocks has primarily the capacity of the shovel in view. Another big shovel is to be put to work later on. The use of the largest size of the shovel, combined with the ability of the crushing apparatus to take anything handled by such shovels, leads to considerable economies. The blasting expense is greatly reduced, as is also the cost of labor. A further and considerable advantage arises from the increased independence of labor conditions. In connection with the efficient working of quarries such as those in Martinsburg, it is quite important that the arrangements for drainage be thoroughly dependable. From the point of view of economy, it is also desirable that the necessary pumping

apparatus be simple and subject to the necessity of only infrequent and small repairs. At these quarries there are two standard pumps built by the A. S. Cameron Steam Pump Works, of New York City, which furnish the necessary clearance from water. The manager reports that the first pump has undergone hard service, has handled a large amount of water with ease, has been used day and night for over a year, and has cost less than \$10 for repairs in that time. The second pump has been placed only recently, and has hardly had time as yet to make its record.

The rock when loaded in the special skip-cars—one skip to a truck—is drawn by locomotives to its destination in the crusher house, and dumped into the hopper bins over the rolls, whether the load consists of one or two enormous blocks or a mixture of big and little stones. Just over the rolls, a horizontal section of the opening of the hopper is a rectangle of about 7 by 10 feet.

The actual crushing is done by a pair of rolls, each 6 ft. in diameter and 7 ft. long. Their cylindrical surfaces are provided with numerous projections or knobs arranged in circumferential and longitudinal lines. All knobs are essentially alike with the exception of those in two longitudinal rows on one of the rolls. The great majority are about 2 inches in height. A circumferential row is in reality an annular rib interrupted here and there. As the rolls are given a rotational movement, the knobs have front and rear faces. These are planes inclined toward each other above. Thus the forward face is a plane extending upward and backward. The inclination to the cylindrical surface is not a steep one. The other knobs, arranged as already said in two longitudinal rows, are of superior height. Their forward faces are quite steep. These knobs arranged in two lines diametrically opposite each other are known as 'sluggers.' They are prominent if not the chief agents in shattering the rock. The two rolls are placed alongside each other, with their circumferential rows immediately opposite. The rolls rotate in opposite directions—toward each other, viewed from above. At full speed with no rock between them, the rolls have a speed of about 165 r.p.m. As the roots of the knobs are 3 ft. from the axis of rotation, they have a velocity of about 35 miles per hour. At any given point where sluggers pass, 330 blows are delivered per minute, or 5½ blows per second. As there are 8 or 10 sluggers arranged in a longitudinal row, these form a body of active sledge-hammers. Furthermore, the sluggers and other knobs operate with the accumulated energy of the heavy rotating weight of the rolls, which weigh about 50 tons each. The shattering effect breaks the rock, regardless of size, in a few seconds.

The crushing rolls are an invention of Thomas A. Edison and were furnished by the Edison Crushing Roll Co. of Stewartville, New Jersey. Each roll rotates upon a shaft 21 inches in diameter. Next to the shaft is a mandrel having an octagonal cross-section. Upon this plane rectangular surface, the crusher-plates themselves are secured by large tap bolts. Ten bolts hold each plate. The plates themselves are 22½ in. broad at the bottom and 3½ ft. long. The maximum thickness, exclusive of knobs, is 5 in., the minimum 4 in. Sixteen such plates and 160 bolts make up the complement belonging to one roll. All tap bolts have a diameter of 2 in., except those which secure the slugger plates. These have a diameter of 2½ in. All threads are V-shaped. No nuts are employed; the bolts are simply screwed into tapped holes in the mandrel. The plates are of chilled cast iron; the mandrel is of cast iron. The shaft is reduced to 18 in. diameter at the bearings. The two shafts may be adjusted at various distances apart, so as to crush the rock to different predetermined sizes. When brought to the minimum distance apart, the product of the crushing operation will be sizes ranging from about 4 in. down. In this position the sluggers barely clear the knobs of the companion roll. The rolls may be placed as far apart as 8 ft. 8 in. between centres. The product will then be approximately 24 in. and smaller. Six-foot rolls readily take care of stones weighing 15 or more tons,

and are able to deal with cubes 7 ft. on a side and weighing 28 tons.

The energy of such a pair of rolls rotating at 165 r.p.m. is estimated in effect at about 4,000,000 ft.-lb. This accumulated energy is important. When the rock is fairly gripped, both rolls tend to rotate in unison. Because of the enormous amount of work done in such a short time, the rotative speed goes down sharply and then slowly recovers itself. The shattering of an 8-ton rock will require about 13 seconds, of which 10 seconds may be required to regain speed. The two rolls are not geared together, but are operated absolutely independently by separate motors. It is supposed that the slugger roll does the greater portion of the work, and probably in the majority of cases its speed falls off more than that of its companion. The motors fall off somewhat in speed, but the reduction in rotation velocity of the rolls is far beyond what can be accounted for thus, as the driving pulleys slip in the belts. Considering this slippage, it is not surprising to learn that the upkeep of belts is one of the chief items of maintenance. The total expense for upkeep is, however, quite moderate. At the works of the Edison Portland Cement Co., in the space of two years, four rolls crushed 1,024,409 tons of rock from sizes running up to 10 tons to a size capable of passing a  $\frac{3}{4}$ -in. perforation. Exclusive of labor, the repairs and replacements cost \$8718.39, an average of \$0.0085 per ton. The plate expense accounted for about one-half; the belt expense for about one-quarter.

At the Martinsburg plant, the rolls are driven by a pair of 200-hp. electric motors. The energy demanded at the most intense instant may rise as high as 3000 to 4000 hp., so it is very necessary to store up energy in the rolls—just as with an ordinary fly-wheel. The maximum demand continues, however, for a very short interval—perhaps half a second, and at this moment the rotational speed has been considerably reduced, so the crisis of the crushing operation is accomplished by one or perhaps two blows of the slugger knobs. Immediately before and after the single blow of a row of sluggers, the demand for energy is much less. The belts which connect motors and driving pulleys are 24 in. wide. The motor pulleys are 32 inches in diameter and those on the rolls 96 in., so that there is a speed reduction in the ratio of 3 to 1. As the rolls are operated in opposite directions, the upper side of one belt and the lower side of the other are tight. One belt has, then, a slack lower side. An idle roll is used to support this. The roll pulleys are mounted directly on the roll shafts, one on either side of the crusher. The successful use of electricity for this service is ample proof of its adaptability for work where shocks are to be expected and taken care of. These Edison rolls are successfully driven by motors totaling only 400 hp. because of the great weight and substantial character of the rotating mechanism. It is doubtful whether the shocks of a rolling-mill are proportionately equal to those experienced with these rolls. The demand for energy at the moment of crisis may be 8 or 9 times the capacity of the driving engines.

At present the capacity of the rolls at Martinsburg is about 1000 tons per hour, but the ultimate capacity is unknown. The present practice is to use the rolls for crushing to a size at least as small as 7 or 8 in. There are, of course, quantities of rock of all sizes below, including dust. It is all valuable, provided it is properly classified. So the problem subsequent to the great crushers is largely one of screening, and if a considerable percentage of the smaller sizes is desired, then supplementary crushing will be employed as part of the procedure. Edison rolls of reduced dimensions may be employed on this service. At Martinsburg the giant rolls are the only crushing apparatus in use at present. Consequently, the smallest sizes are produced in relatively small amounts, and the product is now largely confined to the sizes used in the open-hearth process of steel-making and blast-furnace production of pig iron. To these may be added

the sizes used for railway ballast and road-making. It is proposed ultimately that this plant shall include additional rolls and screening apparatus in order to produce considerable amounts of the smallest sizes, which are used in the manufacture of glass and agricultural fertilizer.

## Alaska Gold Mines Company

Details regarding the Alaska Perseverance mine at Juneau, now the property of the Alaska Gastineau and about to pass to the new Alaska Gold Mines Co., are given in a report by D. C. Jackling and A. F. Holden, from which the following is taken:

We have considered the probable capital requirements for a capacity of 6000 tons per day, which contemplates a hydro-electric power plant; mine development and equipment, including all the necessary living quarters, both at the Perseverance mine proper and at the mill, and driving the long adit. We believe that \$4,500,000 will do this work.

Our belief is that the substantially indicated orebody is about 4500 ft. long by 70 ft. wide. The value of the 600,000 tons of ore that have been mined from this body in three different large stopes indicates that a recovery of at least \$1.50 per ton can be made. We believe that there will be 75c. per ton profit in this grade of ore. The Sheep Creek adit, which will be driven on the vein as the main haulage level, will develop this orebody at an average depth of about 2200 ft. on the dip of the vein, or about 700 ft. deeper than present developments.

The character of this vein is similar in a general way to other large deposits of gold ore in the same vicinity in which the value of the ore at a vertical depth of 1600 or 2000 ft. on the dip of the vein from its apex, is practically the same today as on the surface. We visited these mines and saw their deep levels, and, if there is any inference to be drawn from the continuity of these orebodies, which are not, however, on the same vein as the Perseverance, one might be tempted to say that there is a probability of ore 2500 ft. deeper than the so-called Sheep Creek adit, which we contemplate driving, but while the probability is there of the vein and ore of value extending to great depth, there is nothing today to warrant anybody in stating that it is a fact that such will be the case.

There are substantially 50,000,000 tons in the orebody we consider definitely indicated. There is a probability of another 2000 ft. to the east of the 4500-ft. ore-zone which, from surface indications, would seem fairly certain to contain ore. Beyond this is some 1800 ft. of the vein concerning which we have no final opinion one way or the other, as we visited no workings or outcrops from which we could secure sufficient data to form accurate deductions. While we cannot at this time state that there is ore here, there are several small mines worked almost at the extreme east end of the vein on this property, which indicates that this 1800 ft. will undoubtedly produce considerable ore and perhaps large quantities. If we do not consider this in the probabilities, it is certainly well within the possibilities.

This letter is based solely on a consideration of \$1.50 recoverable value as ore. If one should figure on lower values, assuming 75c. as the total cost of mining and milling, the tonnage now indicated is indefinite, but certainly enormous. We believe that sound mining business will indicate that for the plant now proposed and for operating period of, say, two years, it will be wise to confine our work to the higher-grade ore. There can be, in our opinion, little doubt that at some time in the comparatively near future a much larger plant than the one now proposed will be erected for the purpose of working a larger tonnage of the normal grade ore we now expect will be developed, or of utilizing the apparently vast quantity of lower-grade material. The indicated earnings from the installation now contemplated are approximately \$1,500,000 per annum.

STAMPS and tube-mills erected at the end of 1911, in the Transvaal, totaled 10,775 and 263, respectively.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### American Institute Affairs

The Editor:

Sir—The American Institute of Mining Engineers has labored for some years under three separate difficulties: (1) Ill defined division of responsibility, in the dual control of its activities, between the Board of Directors and the Council; (2) the independence of the secretary of the Council because of his election by the Institute at large, of the body he is supposed to serve; an illogical situation; (3) the possibility afforded by the present form of constitution and by-laws of placing the management of the entire affairs of the Institute in the hands of a single individual.

The Directors are made solely responsible for the funds and property of the Institute by the incorporation laws of the state of New York. The constitution places the management of all its professional and social affairs in the hands of the Council, which may, and which has in the past, in arranging them incurred indebtedness for which the Directors are responsible; but in which they have frequently had no voice. This should be changed so that no expenditure can be incurred except on previous appropriation by the Board of Directors. The secretary has been the executive officer and has the power, under the constitution, of incurring debts in the name of the Institute, auditing the bills and paying them without consulting either of the governing bodies. As shown in the report of the Committee of Five, the Institute has for some years been short of funds. Its annual income has not sufficed to meet all of its financial obligations.

The main reasons for this condition are: (1) The expense incurred by the interest in the United Engineering Society building; (2) high salaries and inefficiency in the office work; (3) the large proportion of life members whose commutation of dues has been spent for current expenses as fast as received, while the obligations of the Institute to them are continuous; (4) the large number of delinquent members carried on the books and supplied with publications. Together, the life members and delinquents are about one-fourth of the total, so that the entire expenses are paid by about three-fourths of the membership.

It is generally admitted the constitution should be amended, and in so doing we believe the difficulties mentioned above should be borne in mind and every effort made to remove them. It is hardly possible to do away with the dual control of Directors and Council without putting the control entirely in the hands of the New York members, which they do not desire, and which would not be for the good of the Institute. The incorporation laws place the responsibility so entirely in the hands of the Directors that in order to have meetings most of them must be residents of New York or vicinity, or the power be delegated to an executive committee of such residents, which amounts to the same thing. For this reason the dual control will have to be continued.

The undue influence of the secretary of the Council should, and can be, obviated by abolishing his election by the membership at the annual meeting and by letting the Council elect its own secretary subject to its own pleasure. A one-man management can be prevented by changes in the constitution and by-laws precluding the occupancy of certain offices by the same individual.

Two policies have been in mind for the future management of the Institute. One is a continuance of the present predominating influence on the part of a single individual; the other a practical divorce of the business management and the professional activities so that they will not come

in contact except at a single point. In the past the Institute has had an especially versatile and energetic secretary; but even in this case the number of those who have not agreed with his policy has increased until they now probably constitute a considerable majority of the Institute. Even if it were desired to continue what is practically a one-man management, and if an individual combining all of the necessary qualifications could be found, it is doubtful whether the Institute, with its present obligations and comparatively small membership could afford to pay sufficient to obtain him. We believe it would be better, at least for the moment, to have a business manager selected by and responsible to the Directors and have the editorial work, so far at least as the selection of material goes, performed by a committee on papers and publications, as is done by most similar societies who attempt to manage their affairs economically; the papers so selected to be turned over to an editor and the business manager, who would attend to the details of publication and distribution.

The expenses of the United Engineering Society building have been incurred and must be provided for. It is therefore either necessary to increase the income of the Institute, decrease its expenditures, or both. The former result can be obtained by making the Institute of greater value to its members, which would probably result in increasing the membership, the latter result by more efficient management at the head office and by eliminating various subsidiary activities not strictly a part of the Institute's business. We believe that the members can be largely increased, as other societies of similar aims and scope have grown largely in the past few years, while the Institute has stood still. An increase in the membership beyond the present number will increase the income much more rapidly than the expense, so that a comparatively small number of additional members would place the Institute in an easy financial position. We believe this to be a better and surer way of providing the needed funds than to increase the dues, which would undoubtedly cause enough resignations to make the financial results uncertain. When a large proportion of the members are dissatisfied and are asking themselves whether they are getting a proper return for their money, it is a bad time to ask them to pay more, unless they can be clearly shown that they are to receive an adequate return. We believe that by lopping off some unnecessary expenditures, by still closer supervision on the part of the Board of Directors, considerable economies can be effected without in any way curtailing the work which the Institute was called into existence to do.

C. R. CORNING,  
GEO. C. STONE.

New York, N. Y., August 21.

### Mining Reports

The Editor:

Sir—My attention has just been called to a letter signed 'C. S. Herzig,' under the heading of 'Mining Reports' in your issue of July 6.

As the late manager of the mine referred to in this letter, I trust you will allow me a little of your valuable space to reply to it. Mr. Herzig is apparently in England, and from the tone of his letter seems to believe that he has some knowledge of mining company procedure in this country. If so, he might have explained that the manager of a mine, being on the mine itself, is not responsible for the publication of any news in any paper. In this case the quotation is taken from a lengthy fortnightly report, and not a cabled one, as Mr. Herzig leads one to infer. The extract was made presumably by the board of directors, who, naturally, are responsible for whatever is published. It is kind of Mr. Herzig to acknowledge the authorship of the italics, although I must confess that I do not see his point. The phrase which he has kindly italicized is the summarized views of the mine manager, who informs his board that, from all the data which he has at hand, he believes the adit which he has been driving for a considerable distance

is nearing the reef—which it is the object of this adit to intersect.

I fail to see on what Mr. Herzig bases his cheap sarcasm. It is not usual in this country among professional men of repute to attack another man's work and management on such flimsy pretext. I can only come to the conclusion that Mr. Herzig has only written you with a view to airing some commonplaces, which, in my opinion, are certainly not in keeping with the high tone and reputation of your paper.

If Mr. Herzig believed the matter of importance, why did he not air his views in the English technical press? Was he afraid that, in view of its contents, his letter might not have been accepted as worth publication?

W. HILDRED.

London, August 5.

### Foreign Trade and Canal Tolls

The Editor:

Sir—Your generous polemics would stay my answering your editorial in the *Mining and Scientific Press* for August 17, but that the argument needs challenging in the interest of a closer scrutiny of our national policies. There are few who do not now regret the folly of the Hay-Pauncefote treaty. It was a work of supererogation, done vain-gloriously by a Secretary of State who sought, in the making of various unnecessary treaties, to pose as a diplomat worthy of the circle of distinguished British dukes and lords and statesmen in which he had been socially prominent through his position as ambassador before the Court of St. James, aided by the unstinted millions of his father-in-law. It was a heavy price America had to pay for social preferment. It would have been cheaper to have paid a better trained man enough to sustain the dignity of the embassy; but we are slow in appreciating the virtue of such economy.

It was a bad bargain, but I agree that we should not, for that reason, decline to fulfil our contract. Nevertheless, interpretation of a treaty in the light of previous diplomatic understandings and of diplomatic precedent, is so universally conceded that these are necessarily taken into account in the application of any convention. Great Britain did not hesitate to construe the Clayton-Bulwer treaty of 1850 in accord with the principle which holds in Common Law as well as in the *Jus Gentium* limiting obligations of a contracting party in the face of permanently continuing injury. So far did Great Britain go in her disregard of the Clayton-Bulwer treaty that two Secretaries of State informed her that they held the treaty annulled by her own acts. Such was the attitude of our Government until Mr. Hay undertook to resuscitate the question. Back of these declarations lay further precedent established by Great Britain in her interpretation of existing treaties, relating to the absorption of the province of Vera Paz from Guatemala, and to her pretensions to sovereignty in the name of her ward, the Kingdom of Mosquito, over the territory on both sides of the Rio San Juan in southern Nicaragua, which constituted the basis of tedious diplomatic correspondence when Mr. Buchanan represented our Government in England, and which was freely drawn upon by Mr. Blaine at the time when he made known to Great Britain that under any and all circumstances it was the understanding and intent of this Government to regard any transisthmian water-way as practically an extension of our coast-line. The drawing up of the treaty without specifically setting aside this pretension on our part would naturally make its interpretation subject to such declaration, after the precedent set by Sir Henry Bulwer in his historic note following the ratification by our Senate of the Clayton-Bulwer treaty.

Added to this exists the remarkable fact that the Hay-Pauncefote treaty lacks an essential to valid agreements, namely, a *quid pro quo*. Even the Clayton-Bulwer treaty, loose and ambiguous as it was, did not fail to set forth, as the reason for our concessions, the co-operation of England in protecting the canal in the interest of the commerce of the two countries. Therefore the violation of the Hay-

Pauncefote treaty by the bill which passed the Senate cannot be conceded, and cannot be claimed until a decision of the Supreme Court covering this point shall have been handed down. It is not a question of dishonor, but one of standing firmly upon the rights appertaining to the American people.

Against the flagrant violation of both the spirit and letter of our treaties with the United States of Colombia, I made earnest protest through the columns of the *Mining and Scientific Press* and elsewhere, and the infamy of that act is a blot upon our Canal policy that must ever make honest Americans blush, but I can conceive no analogy between that case and the one now at issue.

It were to lead far afield to show, as records and statistics, voluminous enough to fill the San Francisco Public Library would amply do, that the policy of protected shipping has given Great Britain a virtual tariff wall for her trade so thick that the United States certainly has never been able to break through it, especially since that famous aftermath of the War of 1812 that tore the sails and dismantled the rigging of our merchant marine. For the first time in 85 years we stand a chance, through a wise measure, of regaining our place upon the sea. The advantage which many had foreseen from the Panama canal is not to be fully realized, but there seems no reason to expect that our inter-coast traffic will be handicapped by tolls, and the admission to American registry of foreign-built ships is a great step in the development of our foreign commerce. Then our unequal trade relations will undergo a change, and the ratio between raw materials and manufactures in our exports will alter in favor of the American wage-earner. The disproportion between the huge increase of prices of staple foods and of those of metals and metal products will be modified. The balance of exchanges will take care of itself. As a matter of fact, such are the needs and demands of different peoples, that reciprocal trade relations exist only to a limited extent. The effectuation of international exchange becomes triangular in any healthy foreign relationships. Without it periods of stagnation and disaster in the operation of a fleet of ships would be frequent.

If we are not to have free toll for all ships, both in domestic and over-sea trade, there still lies open to some diplomat the opportunity of finding the way to revive discriminating duties, which would be a fitting counterpart to the other advantages which the Panama canal is about to bring.

COURTENAY DE KALB.

Tucson, Arizona, August 20.

The Editor:

Sir—May I ask what the prospects are for the employment on the editorial staff of the *Mining and Scientific Press* of a political economist? California has so many unsolved mining and metallurgical problems that it would seem that the regular editors could be kept fairly busy aiding these industries. The space occupied by such labored articles as yours on 'Foreign Trade and Canal Tolls' could be greatly reduced by a trained writer on economics, and the space saved devoted to editorial explanations of why the mining, milling, and developing costs at the Standard mine in Mono county are \$15.85 per ton of ore, as against a maximum cost of \$3 per ton at the Kennedy mine in Amador county, that is now working at a depth of 3600 ft. below the surface. Then, some of the space saved could be regularly devoted to a study of the work that is being done along the Mother Lode, told in such a way that the foreign engineers and business men could learn from the files of the paper the facts about the mines that are being worked in California. The *Mining and Scientific Press* often appears without a single item from the Mother Lode, and in so far as any subscriber depends upon it for a weekly history of mining in California, just to that extent will he be disappointed.

The following editorial from the *Public*, by a trained political economist, will illustrate how space may be saved and a befuddled subject clarified. It may also help

Courtenay De Kalb to get hold of the idea that service for service can be rendered without either party to the transaction being exploited. To those who care to follow this subject, the writing of the American ship-builder, Louis F. Nixon, will be illuminating. He calls attention to one of the duties imposed upon Congress by the Constitution: "To regulate commerce with foreign nations." The editorial follows:

"Something very like pettifoggery is the position of the United States Government with reference to the discriminating tolls at the Panama canal. This canal is either an international enterprise managed by the American government for the general good on equal terms, or it is a national enterprise for national benefit; and that it is the latter the American government has not the face to claim. Then the American government must concede it to be the former. But if it is the former, if that canal is an international affair, the American government has no right in good conscience to impose any tolls upon the commerce of other nations which it does not impose upon our own. To insist upon doing so is in effect to claim the right to make a national monopoly of the whole carrying trade through the canal. And by charging the tolls and then refunding them nothing can be gained but a reputation for bad faith."

G. McM. Ross.

Stockton, California, August 21.

[Choice of subjects for editorial discussion in the *Mining and Scientific Press*, and method of treatment is determined by one rule only—"tell the truth and make it interesting." We think that in the matter of canal tolls we told the truth; an opinion in which we are fortified since our correspondent quotes "a trained political economist" whose opinion evidently is the same as ours. That the subject was interesting to engineers is shown by the fact that it provoked letters from Mr. Ross and Mr. De Kalb. Incidentally, the particular editorial was written only after several requests for information on the subject had reached the editor.

As to the Mother Lode, the *Mining and Scientific Press* publishes all the accurate information about that district that can be had. Unfortunately the majority of the operators refuse to give out for publication the exact facts about their properties, and we repeatedly throw into the waste-basket material sent by local correspondents and which we know to be untrue. Many Mother Lode operators keep their books so poorly that they deceive themselves as to costs; others who have reliable figures and who generously place them at our disposal for our own information, restrict our use of them. Some of the best work of which we know, taking into account all conditions, is being done on the Mother Lode, and some of the poorest. Two well conducted properties have total costs of \$3.50 per ton, and at one the ore now averages \$6 in value. Another property was widely reputed to contain a large amount of \$5 ore, and the manager told the editor that the total operating cost was \$1.60 per ton. Subsequent examination by competent engineers showed the ore reserve to average \$2.80 per ton in value and that there was no possibility of making a profit out of this ore. In our judgment, fortified by that of several of the best experts who have studied the Lode in the past two years, the Mother Lode district today affords one of the best opportunities in the world for development of profitable deep gold mining, but there are unusual difficulties in getting a property in the district upon terms that will permit raising the capital necessary for deep mining. There is the ever-present threat of litigation in case anything of value is found; many properties are held by those who cannot or will not put money into a new venture and who yet require a large cash payment for what at present is worthless; other mines have been sold or bonded on rank misrepresentation; and still others have been badly mismanaged. Along the whole lode with but few exceptions, it is impossible to get accurate data for publication, and therefore impossible for a mining paper, however friendly, to be of much assistance. In the aggregate, we publish a great deal about the Mother Lode, more

than any other mining paper. It is a district in which we believe thoroughly, and we would gladly publish more, provided it be accurate. We will welcome further facts about the district from our correspondent.—EDITOR.]

## Fusing Silica

The Editor:

Sir—In proposing the following modified method for the determination of fusion silica, I believe I am offering your readers a more rapid and convenient method than the usual procedure, and one that is also very accurate. Of course, the chemist must use discrimination in the application of the method; it is not suitable for ores containing barium; and ores with lead must first have a preliminary treatment to separate the lead, but that is usually necessary with any fusion method.

The following determinations, made on a difficult ore high in alumina, will show the accuracy of the method: portion insoluble with acids, 52.4%; silica in original ore, by potassium bisulphate fusion, 37.8 and 38.0%; silica, by standard sodium carbonate fusion, 35.4 and 35.3%; silica, by sodium peroxide and sulphuric acid, 35.4 and 35.4 per cent.

*Method.*—Take one-half gram of ore, fuse in a nickel dish, or iron crucible, with 5 gm. of peroxide mixture (four parts sodium peroxide and one part sodium hydrate); extract with a little hot water, acidulate with sulphuric acid, add 5 c.c. of concentrated acid, and evaporate to fumes. Cool, dilute, filter off silica, dry, ignite, and weigh.

Ores with lead must first be decomposed with acids and fumed, the lead removed by ammonium acetate, and the insoluble residue then dried and fused with peroxide mixture.

ASSAYER.

Washington, August 19.

## Mining Bureau Appropriations

Appropriations for the support of the United States Bureau of Mines as finally granted by Congress are:

General expenses .....	\$ 66,100
Mine accidents investigations.....	320,000
Metal mine investigations.....	50,000
Testing coals .....	135,000
Alaska mine inspection.....	6,500
Books for library.....	1,500
Land for headquarters for mine-rescue cars.....	4,000
	<hr/>
	\$583,100

IN the Brazilian state of Minas gold has been mined from earliest times. It was about 1570 that pioneers, penetrating into the interior of Brazil from São Paulo, discovered that the streams of the south of what is now the state of Minas ran over auriferous gravels. The news spread, and soon parties were converging upon the district from north, south, and east, exploring and colonizing it, clearing ground, raising crops, building towns, and establishing a small but steady export of gold to Portugal. The Portuguese Crown promptly imposed a tax of 20% on all gold produced, creating the practice of smuggling on a large scale and driving the miners to the remoter districts where they might be free from official surveillance. The alluvial deposits were the first to be worked, and then the miners attacked the veins in the mountain side; but both were finally abandoned in favor of the newly introduced industry of coffee planting. Nevertheless, official records state that between 1700 and 1820 gold was produced to the value of £120,000,000, and it is estimated that, in addition, from six to ten million ounces was exported clandestinely. Shortly before the Independence a company was organized to work a gold deposit at Passagem, between Marianna and Ouro Preto, the then capital of Minas, and this mine is still being worked as the Ouro Preto Gold mines of Brazil. Other companies followed, mostly formed in London.

## Special Correspondence

### NEW YORK

AMALGAMATED PUZZLES.—ALASKA GOLD.—COPPER MINE NEWS.—MEXICAN SITUATION.—COBALT.

There has been a little lull in the metal market, though the prevailing quiet has not affected prices so far. The increase in refinery production, as shown by Producers' figures of last month, was a little bit disquieting, though such attempts as were made to manipulate the London market to lower levels were practically without avail. From the figures covering production, it is quite evident that actual conditions have not always been completely revealed during the past few months, and the skeptical attitude maintained by the public has not been without justification. The real climax for the copper situation will come within the next six or eight months, when it will be determined whether or not consumption is to keep pace with production. The copper metal market is in such exceedingly strong hands that factors which ordinarily would be of great weight must under present consideration be ignored somewhat. From the present outlook it is quite safe, apparently, to say that present prices have come to stay for at least a considerable time. Market followers are expecting to see some interesting movements in Amalgamated. Eventually, Amalgamated is slated to be absorbed by the new and enlarged Anaconda Copper Co., which will be wiped out, but before this is done it is said that the City Bank people, who originally stood sponsors for the flotation of Amalgamated, intend to make the stock sell at at least its original subscription price of \$100 per share. Lawson has not been the only critic of Amalgamated's history, and if the stock can be put back to the price suggested, the original sponsors for the company will be able to wash their hands with better grace when the last chapter is written. The Anaconda dividend is expected to be increased, and Amalgamated will probably make an increase in its distribution in order to further this end.

The report of D. C. Jackling and A. F. Holden covering the Alaska Gastineau property should be studied carefully by investors who fancy shares in precious-metal mines. The existence of low-grade milling properties, turning out precious metal even as the porphyries turn out copper, is overlooked *in toto* by far the greater number of individuals who purchase mining shares. The examples of the Alaska Treadwell and the Homestake are largely lost because there is not the glamor of high grade, the romance of nuggets as in Australia, 'pockets' as in the earlier days of California, or small rich ore-shoots from which a few lessees made fortunes in Goldfield. The 'pocket' hunter cannot equip a low-grade milling property, but for the investor some study by way of comparison cannot but prove profitable. The joint report of Mr. Jackling and Mr. Holden opens with bald statement that to equip the property with a mill, a hydro-electric power-plant, living quarters for workmen, and to drive the long adit will require \$4,500,000. The orebody which is to be opened is stated to be about 4500 ft. in length and 70 ft. in width and to contain 50,000,000 tons of ore. Some 600,000 tons already mined from the vein are stated to have yielded at least \$1.50 per ton. Mining and milling costs are calculated at 75c. per ton, leaving a like amount as profit. The mill is to be built to have a capacity of 6000 tons per day, and is expected to earn \$1,500,000 per year. It is worthy of attention that men of such wide experience, and so far from the type of mining promoter who indulges in hyperbole, should wax enthusiastic. Summing up, they say: "The possible tonnages of ore indicated in this property appear to be greater than any vein deposit we know about"; certainly as strong language as could be expected from the gentlemen signing the report. The Alaska Gold Mines Co. is to have a capital of 7,500,000 shares of \$10 each, of which 614,700 shares are to be issued at this time, and the company will acquire \$1,790,000 of the bonds of the

Alaska Gastineau company out of a total issue of \$3,500,000, and also \$9,801,000 par value of the stock, being about 80% of the total stock of \$12,000,000. The balance of the authorized stock of the new company is to be retained in the treasury and will be used in part to acquire the balance of the stock and bonds not under option when same can be bought advantageously. The Alaska Gastineau represents a recent consolidation of the Alaska Perseverance with the Oxford and important Sheep Creek properties, in Silver Bow basin and on Sheep creek back of Juneau, Alaska.

The controlling interests in Butte & Superior have evidently changed their minds in regard to the manner of handling the additional territory adjacent to the original property and recently acquired under options. Instead of an independent organization to be formed as recently announced, a special stockholders' meeting is to be called September 24 to vote on an increase of 100,000 shares of new stock, to be offered to the present holders at \$37.50 per share on a basis of one new share for each eight shares now held; the proceeds to be used in exploring the ground now under option and acquiring same if the developments are as satisfactory as hoped. The Assets Realization Co. has taken over all of the assets of the United Copper Co. All of the Heinzes have resigned from the United board. The Realization company is to advance \$1,250,000 and presumably will proceed with the gradual liquidation of the United Copper Co. What there may be

ALASKA PERSEVERANCE MINE.

in the United treasury is a matter of hazard only; excepting F. Augustus Heinze, no one has known up to the present time. The Assets Realization Co. is an outgrowth of the business of Cobe & McKinnon, of Chicago, who were originally dealers in broken-down real estate projects in and about Chicago; developing some instinct for the work of salvage, the Assets Realization Co. was formed, and under the particular guidance of John W. McKinnon has grown into an exceedingly large institution buying and converting the assets of failed banks, insurance companies, and, on the other hand, financing new enterprises. The Assets Realization Co. has played an important rôle in New York since the 1907 panic, which, by the way, displayed its first violent symptoms in the market for United Copper. Heinze's 'far-flung battle line' does not shorten much. Stewart, Ohio, United Copper, are all in snarls of litigation, reorganization, or liquidation.

The British Columbia Copper Co. is turning out copper at a better rate than ever. The New Dominion Copper Co., which is now controlled by the British Columbia, has made its report for the year ended March 31. The work done was for the most part in the way of experiment and endeavor to get on some basis that would admit of ore shipments being made to the Greenwood smelter of the British Columbia and allow some profit to each organization. Owing to the fact that during a part of the time the British Columbia, like the Granby, was forced to import Pennsylvania coke, the experiments so conducted were hardly a fair test. Under the present arrangement a smelting charge has been agreed upon as fixed by a joint committee of engineers, and on this basis the British

Columbia guarantees to the New Dominion a profit of 15c. per ton on its ores.

The melon which was to be served to the stockholders of the International Smelting & Refining Co. is apparently not to be cut as yet. The company has been active in new construction. The Tooele smelter, the lead stacks and furnaces near Chicago, the enlargement of the Raritan plant have cost several millions of dollars, and stockholders rather expected some profits in the way of subscription rights. However, as the company is earning considerably more than its 8% dividend, it has a surplus to use for its requirements and can save interest charges by borrowing 6% money in the market rather than put out additional shares on which it would have to pay 8%. Earnings are said to be running more than 15% at present.

Notwithstanding the fact that the Shattuck-Arizona property is under option to some people who are trying to place it with French capitalists, plans are proceeding for the construction of the smelter at Douglas, and bids will probably be advertised for early in September. The management of the Anaconda Copper Co. has purchased the Oro Fino gold mine, which adjoins the Southern Cross near Butte, for \$250,000. The Southern Cross was purchased by the Anaconda some months ago for \$500,000. Both of these properties lie in the Georgetown district, and the Anaconda people are extending the Butte, Anaconda & Pacific railroad to take care of the shipments from these mines. The sale of the Chemung Copper Co. to the Phelps-Dodge people for \$1,350,000 in cash has been ratified. A final distribution will be made by the Chemung management, and the stockholders will receive about \$6 per share.

The Mexican situation is rather exasperating. It was taken for granted when the Speyer loan was consummated that quiet would ensue and the development of the country proceed with added energy and vigor. Now there is but uncertainty, and it is by no means uncommon to hear mining men in New York express a wish for the hand of Diaz or another equally stern to grasp the sword and restore peace. The San Toy Mining Co. has just published its report for the half-year ended June 30, showing a net profit for the period covered of \$4795. The principal item of interest is the note that while it may be possible to continue operations, no exploratory work can be undertaken until tranquillity is at least so far restored as to make it possible to employ and hold skilled laborers. During July the mill of the El Oro Mining & Railway Co. was in operation 30 days, crushing 20,190 tons of ore and treating 14,840 tons of old tailing, the recovery in bullion being worth \$169,420. The working expense was \$99,100; expenditure on development, \$16,820; mine profit, \$53,500; railway profit, \$9170; and total profit, \$62,670. The sum of \$1770 was spent upon permanent mine improvement.

Cobalt, while absolutely without any sign of life market-wise, is experiencing something of a revival of excitement. This week the land near Haileybury, known as the Gillies Timber Limit, was thrown open to prospectors, and a Jack London midnight stampede or 'mush' was seen. One thousand men participated in the race from the line to points where recent discoveries of silver were made. Claims were staked in frantic haste, and the claimants then raced for the registry office to file claims. In Cobalt proper the work of production is exceedingly creditable. Shipments for the week of August 17 were \$51,439 in bullion, and 333 tons of high-grade ore, which brings the week's shipments nearly to the high record. The fact remains, however, that the public has forsaken Cobalt issues, and apparently pays no attention to production figures. Last year was supposed to mark the 'peak of the load' which Cobalt could carry, but this year so far has seen each month do a little better than the corresponding month of last year. McKinley-Darragh made the record shipment last week, sending out one carload of 38 tons of ore, running a little better than \$4000 per ton, the total value being \$142,231.

## BOSTON

CALUMET & HECLA DIVIDEND.—ALASKA GOLD MINES.—KUSKULANA COPPER COMPANY.

Every time there is a Calumet & Hecla dividend declared Boston rejoices, for it means the distribution of a large sum of new money among the city's 'best families.' The latest declaration of a dividend of \$12 per share for the third quarter of 1912 was the biggest thing in a monetary way which has happened to State Street for many a day. It may be a coincidence worth mentioning that the quarterly dividend is precisely the amount of stock paid in per share on the company's original capitalization. Three months ago Calumet declared a dividend of \$10 per share; six months before that it was \$8, and a year ago the rate was only \$6. So the rate has been doubled in the past year. Another declaration of \$12 per share will make the payments for the year total \$42, the highest total since 1907. In 1911, \$24 was paid; in 1910, \$29; in 1909, \$27; and in 1908, \$20. The highest annual dividend payment made by the company was \$100 in 1899. The company is earning enough to spare \$20 per share in dividends for the quarter, but has \$1,000,000 in 5% notes to retire on September 1. With its subsidiaries coming into the producing and earning ranks, one by one, as the result of ample financing and excellent management, Calumet & Hecla takes on a much stronger outlook than it did a year ago, when there was so much talk about the days of the good old company being numbered. Alaska Gold Mines stock has been traded in on the Boston and New York curbs at around \$7 and \$8 per share. The trading is based on the stock 'when issued.' This is for stock upon which \$5 has been paid, the other \$5 being due next July. It is understood that there will be an over-subscription of the private offering of the stock by the bankers, Hayden, Stone & Co. Interest in Alaska is increasing. The governing board of the Boston curb has admitted to trading the 100,000 shares of the Kuskulana Copper Co. of Chitina. The company has a capitalization of 250,000 shares, par \$10. George H. Morrill, of Boston, is president, with Boston, Athol, and Leominster men as officers and directors. The stock has been moderately traded in around \$4 per share.

## TORONTO, CANADA

RUSH TO GILLIES LIMIT.—COBALT IMPROVES.—PORCUPINE RECOVERY.—LABOR INVESTIGATION.

Cobalt is again in the limelight. Interest in the Porcupine district has for some time been declining, owing to the closing down of many once promising prospects, and the absence of any official or other reliable information as to the results of milling operations at the leading mines. 'Estimates' by professed experts of the approximate output appear from time to time, only to be adversely criticized and contradicted by others. The effect on the public mind is demonstrated by an apathetic and sagging market, principally characterized by the making of new low records. The great event of the week has been the opening to prospectors on August 20 of about 4000 acres of the Gillies Limit, lying to the south of the Cobalt area proper, followed by a rush and a fierce competition by a crowd estimated at between 1500 and 2000, struggling in a midnight scramble for 200 locations. The chance attracted prospectors from the mining districts of northern Ontario, hundreds of whom camped on the ground for days before the official opening, and had their claims picked out ready for staking at the midnight hour. Every trick and device to get there first was resorted to, some of the claimants having erected tents and set corner stakes inside, in defiance of the regulations. Then followed a rush to the recording office at Haileybury, which did not open until 8:30 on the following morning, and a wild scrimmage to secure priority in recording. So great was the excitement for several days in advance of the opening that predictions of violence and possible bloodshed were freely made, but fortunately every-

thing passed off peacefully. It now appears that all this haste and struggle was futile, as all applications for locations will be considered without regard to priority, and the claims awarded in case of dispute to the applicant who can give the best proof of actual discovery. It goes without saying that there are many contested claims, and the rush is likely to be followed by much litigation. And, after all, it is doubtful whether the lucky ones have secured anything of actual value, except perhaps to the company promoter, as before throwing it open the Limit had been examined by officials of the provincial Bureau of Mines, who failed to make any discoveries. The Government some time ago sold locations in the northern part of the Limit for upward of \$400,000, and considerable development was done on the Provincial mine and the Waldman, Wyandoh, and Cleopatrina locations, but operations have proved decidedly unprofitable so far. There is an increased demand for Cobalt stocks, with a slight upward tendency in this long-depressed market, and some properties which have been regarded as hopeless are looking up. The Cobalt Central, now known as the Penn-Canadian, is in active operation and has shipped 32 tons of high-grade ore, taken from the 110-ft. level. A large body of milling ore is being developed on the 305-ft. level, and the old mill, which has a capacity of 100 tons per day, is being refitted for the treatment of a large tonnage of low-grade ore now on the dump. Steady development has been for some time in progress at the Bailey, which is preparing to make a shipment. The McKinley-Darragh has made a new record for the value of a single shipment from the Cobalt camp, having recently sent out a carload of ore containing 231,270 oz. of silver valued at \$142,231. The ore averaged as high as 13,000 oz. The Beaver has found good ore in the diabase underlying the Keewatin formation, which is regarded as of great importance, as showing that the productiveness of a mine is not necessarily terminated when the diabase is reached as appeared to be the case with the Timiskaming. The Curry Lorrain has been reopened and a shaft will be put down close to this property. Other South Lorrain properties, formerly closed down which are now being worked, are the Bellellan, the Alice Lorrain, and the Sharpe Lake. The British American Cobalt, a Montreal company, is being wound up, an attempt to raise funds by the issue of treasury stock having proved unsuccessful. John McLean and Frank Gilmour, the two high-graders who robbed the Nipissing mine by the ingenious method of dipping a cold steel bar into the molten metal at the refinery and withdrawing it with silver adhering to it, each received sentence of two years imprisonment. A Finlander named Johann Salas, alias John Perga, who was arrested at Niagara Falls with 40 lb. of pure silver in his possession which he admitted having obtained at Cobalt, was sentenced to six months imprisonment. George MacNaughton, formerly manager of the Trethewey, has accepted the position of manager of the St. Anthony gold mine in the Sturgeon Lake district.

Members of the Associated Boards of Trade of Ontario to the number of about 80, visited the mining districts of northern Ontario recently, leaving Toronto on August 13 accompanied by W. H. Hearst, Minister of Mines, and other officials. At Porcupine they were present at the clean-up of the Hollinger mill, which yielded gold to the value of \$18,000. At the Dome the daily tonnage of ore treated is 'semi-officially' stated at about 350 tons. A body of ore directly under the big dome at the 200-ft. level has been opened up in the cross-cut and will be connected with the mill by a raise from this level. The Crown Chartered property is likely to change hands. An engineer representing Rochester, New York, stockholders, has been making an inspection of the mine with a view to their acquiring a controlling interest. A payment of \$35,000 on the property has fallen due and a meeting to be held in Montreal in a few days at which the course to be taken will probably be decided upon. At the Vipond mill four additional plates are being placed, making the total number 10, which is expected to increase the percentage of recovery. The Standard, which has been closed since June, has been forced

into liquidation, and its assets, comprising two claims west of the Preston East Dome, will be sold by auction.

The Ontario Government has commissioned Samuel Price, mining commissioner of the province, to make an investigation of underground labor with a view to obtaining full information as to the need and desirability of legislation providing for an eight-hour day. The question was introduced at the last session of the legislature, the proposed restrictions being strongly opposed by the mine-owners, and action was postponed pending further investigations. Mr. Price will hold meetings at the principal mining centres at which both sides will be heard, and he will also study the effect of the eight-hour law where it is in force.

## LONDON

### SUDBURY NICKEL MINES.—WANDERER IN RHODESIA.

The Mond Nickel company does not publish any commercial or technical details, and its yearly reports are of the baldest. All we know is that the company owns copper-nickel mines at Sudbury, Ontario, and a refining plant for the matte at Swansea; that it produces metallic nickel and copper sulphate; and uses the Mond separating process. The report for the year ended April 30 shows that its prosperity continues to increase. The net profit was £154,364, out of which £7718 has been paid as directors' remuneration, £26,666 as 7% preference dividend, £45,906 as ordinary dividend at the rate of 16¼%, and £26,131 as dividend on the deferred shares; £35,000 has been placed to various reserve funds, and £41,381 carried forward. The

WANDERER MINE, RHODESIA.

dividends are the same as the year before, but the amounts placed to reserve and carried forward are greater. During the year, £250,000 5% debentures have been issued for the purpose of completing the new smelter works at Coniston, Ontario, and for extending the works at Swansea. The chairman, in addressing the shareholders, stated that the demand for nickel expands steadily. He expressed the hope that the British Government would eventually adopt a coinage containing nickel, as a substitute for the present cumbersome coppers. The British Government makes nickel coins for use in the Crown Colonies, and supposedly backward countries like India, China, and Central Africa already have such a coinage, while the nickel coins of America and Europe are well known.

The Wanderer is a Rhodesian mine exploiting a large and soft low-grade gold-bearing lode at a low cost per ton of ore. The company was formed in 1899 to acquire the Wanderer, Ashton, and other gold properties in the banded ironstone of the Selukwe district of Rhodesia, and production started in 1902. In the summer of 1909, the company was reconstructed and additional capital raised, for the purpose of purchasing the Camperdown property nearby. The report for the year ended April 30 shows that 219,400 tons of ore was mined and treated by dry-crushing with rolls and cyanidation; of this amount 20,847 tons came from the Wanderer, 9993 tons from the Ashton, 62,794 from the Kemerton, and 125,766 tons from the Camperdown. The assay-value of the ore averaged 2.6 dwt. per ton, and of the tailing 0.6 dwt. The yield was 21,740 oz. or 2 dwt. per ton. The output of ore was 24,166 tons greater than that of the

previous year, which itself was a record. On the other hand, the assay-value of the ore and the yield per ton were less by  $\frac{1}{2}$  and  $\frac{1}{3}$  dwt. respectively. The amount left in the tailing was  $\frac{1}{6}$  dwt. less this year as compared with last year. The working cost was 7s. 6d. per ton as compared with 8s. The development done amounted to 8647 ft., an increase of 2318 ft. over the previous year. A large amount of overburden, 79,917 tons, was removed at the Camperdown and Kemerton mines. The revenue from the sale of gold was £92,365 and the working cost £82,631. In addition, £2092 represented London expenses, and the profit, £7902, was carried forward. The ore reserve is estimated at 350,925 tons, a decrease of approximately 70,000 tons. During the year, Percy Tarbutt & Co. have resigned as consulting engineers and were succeeded by Noel Griffin; H. Wiley is now manager in place of J. B. Little. A serious blemish in the detailed report on the development work is the frequent omission to state the width of the ore. Thus a raise "was put up 41 ft., of which 10 ft. averaged 7.37 dwt." per ton. This conveys nothing unless the stoping width is given.

### SALT LAKE CITY, UTAH

BINGHAM WAGES.—COPPER OUTPUT.—PARK CITY.

Bingham miners after September 1 will share the prosperity of the industry, due to the high price of copper. When the metal was selling at low figures, a reduction in the wage scale was made, with the promise that there would be an increase when the price of the metal justified it. This promise has been fulfilled by the Bingham Mine Operators' Association, a general increase averaging about 25c. per day having been granted. Machine men in the future will receive \$3.25 per shift, helpers \$3, hand steel miners \$2.75 to \$3, hand trammers \$2.75, and mule trammers \$3, other classifications of labor being paid in proportion. This is substantially the scale paid before the cut. The labor situation has been precarious at times in Bingham, but it has always been dealt with firmly, and serious trouble has been averted. The recent move of keeping faith and advancing wages, it is believed, will check smoldering discontent.

With some of the financial burden lifted from the company, and transferred to the shareholders, Ohio Copper is giving a better account of itself. It is stated unofficially that operations netted about \$36,000 during July. Part of the third section of the mill is in operation, and it is declared by people connected with the management that three full sections will be working in September, treating 3000 to 3500 tons per day. The third section is expected to handle 1200 to 1500 tons, while each of the other two sections is handling about 1000 tons each per day. Since the first installment of the \$1 assessment has been pretty well paid up, some of the local creditors have received their money, and the credit of the company has thus been improved. Until the second installment of the assessment has been paid, it is probable that nothing definite will be done in the way of contracting for new equipment. The production of Utah Copper is steadily increasing. July, with 11,160,034 lb. production, set a new record for the property. D. C. Jackling says the August output will be around 12,000,000. Early in September the remodeled Arthur mill should be in operation, so the goal of 150,000,000 lb. of copper per year does not appear to be far distant.

Two of the largest Park City mines—the Daly-Judge and Daly West—have decided to contract the greater portion of their development work during the coming year. James A. McIlwee & Sons, of Denver, have signed contracts to drive all drifts and cross-cuts in virgin ground. The same concern is negotiating with other mines in Park City to contract this class of work. The high price of zinc is bringing prosperity to some of the old producers in Utah. Horn-Silver of Frisco, one of the pioneer mines in the state, has recently entered into a contract to ship an initial consignment of 1000 tons of zinc ore from the dump to Bartlesville, Oklahoma, to net \$17.50 per ton.

### BUTTE, MONTANA

NORTH BUTTE CUTS RICH ORE.—COPPER PRODUCTION FOR AUGUST.—BARNES KING.—STEWART MINING COMPANY.

One of the most important finds ever made in this city and one of the richest ever brought to light in the North Butte property was uncovered the other day when the Edith May vein was cut on the 2400-ft. level. It has a width of 25 ft. and is mineralized from wall to wall and is south and east of the shaft. The poorest assay yet made shows 4% copper and the general average is between 10 and 12%. Several months ago when the North Butte company management failed to find ore of considerable richness in the cross-cut for the Edith May vein on the 2200-ft. level there was much disappointment. After much calculating it was decided to drive on the 2400-ft. level for the vein, and after running a cross-cut it was found.

The Radersburg people, and especially the mine-owners, are much disappointed over the stoppage of work on the line from Three Forks into the district. During the summer work had progressed satisfactorily, and just as the roadbed was ready for the rails financial difficulties arose and work has ceased.

The possibilities of Butte as a great zinc-producing centre are attracting more attention every day. A few days ago W. A. Jones, of Mineral Point, Wisconsin, who is the head of one of the largest zinc manufacturing concerns in the world, stopped off in the city after a trip through the National Park. In speaking about his visit he said: "I confess that I was not prepared for what I understand is more or less common knowledge here—that your zinc industry promises to grow to tremendous proportions. I have been amazed at what I have learned here of your zinc production, both actual and prospective. I am so interested that I am coming back, and it is altogether probable that we will purchase ores from the district and may get into the mining game ourselves here. The zinc industry is growing in importance, and I question if your people right here realize the value of your zinc properties. It is certainly bound to add to the wealth of the city. Like copper, zinc is a metal the world must have, and I feel that in the production of the metal your district is destined to have an important part."

The copper production for the month of August will run about 24,700,000 lb. for this district. This is just about the same as in July. With the first section of the Washoe smelter again in operation, the September production will probably be increased by at least 2,000,000 pounds.

The Barnes-King company in its operations of the North Moccasin property will be managed by George McGee, who was in charge of the mining conducted in the Barnes-King. Mr. McGee is thoroughly familiar with the North Moccasin ground, and only a short time ago he was in the city and had a consultation with C. W. Goodale and others as to the plan of operations, and an understanding was reached as to the mode of procedure. Active mining will be started in a few days. The North Moccasin will be worked through the Barnes-King shaft, as the two properties are connected and the Santiago claim adjoins the Barnes-King at the east end.

The Butte Central Copper Co. mill will be ready for operation by the last of September. Practically all the machinery is now at the building.

F. A. Heinze has more than a two-thirds control of the stock of the Stewart company, and, according to information received here, he intends to amend the articles of incorporation so that stock of other properties, including its own stock, can be purchased. Carter, one of the directors, who is fighting Heinze and wants a receiver appointed, says that with the proposed amendment to the articles of incorporation, Heinze will be in a position to pour Stewart earnings into the treasury of the Ohio company, and thus secure a new lease of life for the Utah company. Carter further points out that Heinze will be in a position to sell his own Stewart stock, which he declares Heinze got for little or nothing.

## General Mining News

### ALASKA

#### CORDOVA

The Alaska Consolidated Copper company has 15 men working on its Kuskulana claims. A winze has been started on the lower levels of the Valdez claim, on Nugget creek, and will be sunk 250 ft. An adit will be driven 250 ft., and should cut the vein at a depth of 125 ft. Pumps and power plant have been ordered for the mine. It will take some time to open the copper country, as there are difficulties in getting supplies and machinery. About 100 men are at work in the district. Around Nugget creek gnats are large and ravenous, so all the men working around the dam have to wear gauze. Rich ore has been opened on four claims on the Tasnuna divide. A lode has been traced for 200 ft., and is 12 to 30 in. wide. It has been opened for 14 ft., and assays give \$1872 per ton. Surface samples gave \$164 per ton.

#### JUNEAU

During July, the 240-stamp mill of the Alaska Treadwell worked 29.64 days, and the 300-stamp mill 29.70 days, crushing a total of 81,116 tons of ore. The estimated gross value of free gold was \$118,216, and that from 1650.47 tons of concentrate \$102,186, a total of \$220,402. The estimated realizable value is \$218,198. Operating expenses were \$78,349, and construction \$13,967, leaving the net profit at \$125,882. The yield per ton was \$2.71. Development totaled 947 ft., and the stock of broken ore decreased 12,676 tons. The Alaska Treadwell company has declared dividend No. 98, of 75c.; Alaska Mexican No. 67, of 35c.; and Alaska United No. 20, of 50c. per share; all payable August 28.

#### NOME

A large dredge is being erected by H. Greenburg and associates, who are to work the third beach line. The dredge

MAP SHOWING THIRD BEACH LINE.

is a Bucyrus make, and will cost \$175,000 and should handle over 3000 cu. yd. per day. Drilling has proved the ground worth 39c. per cubic yard. Ground on the Bessie claim will be thawed for the machine.

### ARIZONA

#### COCHISE COUNTY

Something like a boom has started at the Johnston camp. It is said that the Centurion has been acquired by the Lewisohns. It consists of 23 claims, and a good deal of 7% copper ore has been blocked out. The Bonanza Belt company is shipping 40 tons of ore per week from its Peabody mine. In four months the net smelter returns were \$17,000. The main shaft of the Republic mine is down 820 ft. Ore is being broken on the 720-ft. level which averages 6% copper. About seven carloads per month is shipped. The Mammoth is also shipping ore.

Johnston not only has plenty of copper ores, but is near the shipping station for either the Douglas or El Paso smelters.

#### GILA COUNTY

(Special Correspondence.)—Churn-drill hole No. 8 of the Southwestern Miami Development Co., whose claims lie to the southwest of and adjoining the Live Oak mine, is 860 ft. deep, in chalcocite-bearing schist. Chalcocite first appeared at a depth of 720 ft. in small quantities, and is now reported to be proved. Hole No. 7 is 805 ft. deep in mineralized schist, the sludge from drilling being heavily iron stained. Hole No. 6 is 825 ft. deep in schist. Churn-drill hole No. 3 of the South Live Oak Development Co. is 125 ft. deep in silicified schist, carrying copper in the form of silicate and oxide. The hole is on the hill near Needle mountain, at the northern end of the property, nearly a mile from the first two holes. Water for drilling is pumped 7000 ft. through a vertical distance of 700 ft. To protect itself against probable results of the recently enacted miners' lien law, the Old Dominion company has posted a notice requiring all lessees to give a bond of \$5000. This will work a hardship in many cases. The law provides that a lien shall attach to a mining property for unpaid sums due for labor, or material furnished under contract, with the owner or his agents, or with a person working the property under lease, option, or contract to purchase. The construction of the spur from the Arizona Eastern railroad to the Inspiration mine has been started with a force of 50 men, which is being increased as rapidly as possible. The two Chilean mills in the first unit of the Miami concentrator are being replaced with three 8-ft. Hardinge pebble-mills. The fourth and sixth units are already equipped with the latter type of fine-grinding machinery, and Hardinge mills will eventually replace Chileans in all six units.

Globe, August 22.

#### GREENLEE COUNTY

The new concentrating and cyanide plant of the Twin Peaks company, near York, is being erected as fast as possible, and machinery is arriving. The mine is equipped with a 160-hp. air-compressor, and steam-hoist capable of lifting from 1500-ft. depth. The new mill will cost about \$35,000.

#### PINAL COUNTY

In explaining why part of the Ray Consolidated plant was idle, D. C. Jackling said: "At Ray our milling equipment has always been far ahead of the ability of the mine to produce the quantity of ore required by the concentrators to keep the various units operating to full capacity. This is due to the fact that, in the original development of the property, we accumulated a large stock-pile, so that when the mill was first started ore was drawn from the mine and dumps. It did not take long to exhaust the latter, and since then we have been exerting every effort to open up enough places underground, from where we could take all the ore that the mills required. To date, all of our ore has practically come from No. 1 shaft, No. 2 having been in a position to send but a small quantity to the surface; but we are rapidly remedying this situation, and before long each shaft will be able to raise 5000 tons per day if necessary. There are not sufficient openings to get the ore out yet. All the ore coming from the property still comes from above the 100-ft. level, which accounts for the ore being below 2% copper, but as soon as the main ore-levels are reached, the grade will be raised to the figures originally furnished."

### CALIFORNIA

#### AMADOR COUNTY

(Special Correspondence.)—Within a few weeks the sinking of the 3800-ft. Argonaut shaft to an additional depth of 150 ft. will be under way. The total of 3950 ft. on the incline corresponds to an approximate vertical depth of 3400 ft. The Argonaut already is the deepest incline mine on the Lode. A station will be cut at the 3900-ft. level and development started. The recently installed electric hoist is giving satisfaction. The 40-stamp

mill is treating about 200 tons of ore per day. R. S. Rainsford is manager. The winze from the 1500-ft. level of the Zeila is reported to be in ore of higher grade to that showing above. The shaft at the South Jackson has gained a depth of 250 ft., and is going down to 500-ft. depth. From the latter point extensive lateral work will be done. San Francisco capital is interested. Jeffrey Schweltzer is manager. Development is still under way on the 2700 and 2800-ft. levels of the Central Eureka. About 125 men are employed. Arrangements are being made for sinking the new shaft at the Bunker Hill. In the Volcano district much activity is reported. At the Mountain King a 3-ft. shoot is receiving attention. The richer ore, occurring in narrow streaks, is alone extracted and crushed with mortar and pestle, the lower grade being stored for future milling. The vein was recently discovered by B. Pitts after the former owners had abandoned the property. At the Stud Horse promising ore is showing, but lack of water prevents milling. Prospecting is under way on several claims, but work is handicapped by lack of water.

Jackson, August 24.

#### INYO COUNTY

The Emma Gulch mine has over 6000 tons of low-grade ore on its dump, assaying from \$2 to \$6 per ton. The mine is close to the Monster and Bunker Hill, and the three could be worked with one mill. A large orebody has been opened in Homestead canyon. On account of high freight rates, no ore under \$50 per ton can be profitably shipped. Other mines in the district which require capital to work them, are the Monster, Bunker Hill, Lexington, Old Soldier, Buckhorn, and Never Sweat. They are said to have produced low-grade ore, have a fair quantity in sight, and have water. During July the Skidoo mines mill treated 1201 tons of ore for bullion worth \$21,733. Development expenses were \$1054, and operating, \$6794, leaving net profits at \$13,885. The time lost amounted to 10 5/12 days.

#### SIERRA COUNTY

A gasoline engine has been fitted to drive an air-compressor at the Kirkpatrick mine, near Mountain House. At the Rattlesnake gravel claim it is intended to extend the adit 25 ft. before further raising. This is expected to bring it directly under the channel. Two men are driving a cross-cut from one of the adits at the York mine, below Downieville. Survey work is under way on the proposed power-line to the Telegraph mine. It is intended to reopen the 'Dutch tunnel' on White Bear ground which was driven many years ago. It is said that rich gravel, from \$50 to \$125 per carload, has been produced from the Bellevue mine, between Gibsonville and La Porte. A bond has been secured on the Monitor group of gravel claims adjoining the Bellevue. The purchase price is \$25,000, one-half of which is payable at the end of the fourth year of the five-year term. A shaft will be sunk 400 ft. The group comprises 480 acres, and there is plenty of mining timber available.

#### TRINITY COUNTY

(Special Correspondence.)—The Trinity Reduction & Mining Co. is driving adits and drifts in search for ore below the main deposit. Indications are reported as favorable. A large percentage of the upper deposit has been mined. At the Wagner mine, Coffee Creek district, the adit has been extended over 1000 ft., and it is expected to intersect the vein within about 125 ft. On the surface this vein shows excellent size and gold content. The adit has already cut two veins, one about nine feet wide, the other being somewhat smaller. Power drills are used in the driving, and no attempt has been made to develop the intersected veins until the completion of the adit work. The owners contemplate the erection of a 10 or 20-stamp mill. This is the property for which an offer of \$250,000 was refused last year. P. A. Wagner, of Berkeley, is manager and principal owner. The Trinity Dredging Co. is about to commence operations with its large dredge

near Lewiston. The ground has been thoroughly sampled and prospects are said to be exceedingly good. The Trinity Consolidated Hydraulic Mining Co. has a force of men prospecting several of the claims it holds under option in the Weaverville district. The company has opened large reserves of gravel in the Union Hill and Douglas City mines, two of the largest hydraulic properties in the county. It is again rumored that a deal is pending for the sale of La Grange, the largest producing hydraulic property in California. The Craig Mining Co. is erecting new equipment at the Globe, Chloride, and other mines of its group near Dedrick. Ore development is reported to be satisfactory. Lack of water has naturally hampered placer mining this summer, but most of the companies have placed affairs in shape for an early season this fall.

Weaverville, August 24.

### COLORADO

#### GILPIN COUNTY

Good milling and smelting ore has been opened at the Gilpin Orion mine, on Bobtail hill. At the 250-ft. level a drift has been extended east for 37 ft., and west 27 ft., showing 24 in. of ore, yielding \$9 and the 'tailing' \$1.50 per ton. A 4-in. vein of smelting ore returns \$65 per ton. One load of smelting ore from the Pittsburg mine yielded \$1704 at the sampling works. This came from stopes on the 900-ft. level. Seventy tons is being treated at the Polar Star mill. The 900-ft. level is in about 575 ft., and pay-ore has been opened for some distance.

#### LAKE COUNTY (LEADVILLE)

A company has been formed to work the old Belgian mine, which is situated between the Adelaide, Frenchman, and Flagstaff mines. There is a fair showing of ore at present in the mine. Lessees have sunk the Annie shaft, on Fryer hill, to 260 ft., and have passed through six feet of iron ore, and are now working in a red flint which averages about 29 oz. of silver per ton. Sinking at the Gypsie and McRae shafts has been retarded by recent rain. The new shaft at the Columbine property, on Sheep mountain, has opened good ore. Several carloads of ore from the lode cut in July have been shipped. The face assays 25% lead and 300 oz. of silver per ton. Some high-grade lead ore is being sent out from the Ella Beeler tunnel, in Iowa gulch. The ore is friable and assays 40 to 60% lead, with a little zinc, gold, and silver. Hoists at the Blaine and Tip Top should be finished at an early date.

#### SAN MIGUEL COUNTY

(Special Correspondence.)—The new middling re-treatment plant at the Tomboy mine has been started and is giving good results. The whole mill has lately been extensively overhauled and many improvements made. The construction of a Trenton aerial tram will be started shortly. This will be used to convey concentrate from the mill to the railroad; and also to bring up all supplies.

Telluride, August 20.

#### TELLER COUNTY (CRIPPLE CREEK)

According to J. Stewart, mine inspector, there are now 3300 men working in the district, this including about 250 lessees. The Portland company is erecting a change-room, 40 by 60 ft., for the ore-sorters. The Golden Cycle and Vindicator mines also have change-rooms. The Kavanagh mill has treated 2000 tons of \$2.42 ore, and paid a dividend of \$2500. Plans for the improvement of the district include suggestions for starting the fourth drainage tunnel, which would allow an additional drainage of 500 ft. below the present level. Rich ore is being broken over a width of four feet on the 750-ft. level of the Empire shaft, and 900-ft. level of the Lee shaft. About 80 carloads of ore will be shipped during August. The El Paso company states that during August about 120 cars would be sent out, with a value of nearly \$30 per ton. At the 1000-ft. level, the drift on the main C. K. & N. shoot continues to open good ore. Development of the south vein on the 1500-ft. of the Vindicator has proved it to be as good as on the 1400-ft. level.

**IDAHO****COEUR D'ALENE**

The Bullion mine is shipping 100 tons of copper ore to the East Helena smelter. Work has been carried on at the mine since last spring. J. Miller, of Portland, has been inspecting the Western Silver-Lead property in Government gulch, and work will be started. An air-compressor and pump have been ordered. The mine has been shut down for some years, and the shaft with workings from 400-ft. depth are full of water. During July the National Copper mine tunnel was driven 300 ft. Delay was occasioned by a large fault, which required careful timbering. After going through this, a shoot of ore 8 ft. wide was cut, with 6% copper and 1.5% lead. Later on, one 18-in. and one 15-in. vein were cut, but of low value. At a meeting of the Surprise company a vote will be taken on the scheme of taking over the Highland Chief group. The latter consists of 10 claims adjoining the former, and the vein is a continuation of the Surprise vein. Average assays show 8% lead, 16% zinc, and 6 oz. of silver. The Highland Chief also has valuable water and timber rights. The Surprise group has 9 claims and a 100-ton concentrator and other plant. The proposed capital of the new company is \$1,200,000.

**IDAHO COUNTY**

At the Mascot mine, at the mouth of Kirk's fork, the lode is about eight feet wide and has been opened by an adit to a depth of 125 ft. The St. Lawrence vein is 5 ft. wide and pay-ore has been opened for 500 ft. Foundations for the new mill are about finished. It will be driven by water-power, of which there is plenty all the year. A one-stamp mill has for some time been yielding profitable returns from the Little Butte mine, on Deadwood mountain. This mine is opened by an adit which is in about 1000 ft. The lode is 60 in. wide, the high-grade section being 14 in. wide, and the first-class ore yields about \$30 per ton, and the second class about \$10 per ton.

**SHOSHONE COUNTY**

During the year ended June 30 the Stewart Mining Co.'s gross profits totaled \$315,355. Development expense was \$62,769. The present cash on hand is about \$195,000. Owing to economies effected, the cost of labor and supplies has been reduced to \$2.02 from \$2.24 per ton. It has not been considered wise to pay any dividends during the term, because of the threatening attitude of the Ontario Mining Co. as regards the orebodies. This company owns property contiguous to the Stewart, which it works through the Coeur d'Alene Development Co.'s tunnel. A suit has been brought against the Stewart company by Mr. Carter, a director. All other obligations have been settled, and one-third of the Development company's and 90% of the Coeur d'Alene Metal, Mining & Smelting Co.'s stock have been acquired.

**MONTANA****SILVERBOW COUNTY**

(Special Correspondence.)—While prospecting for a water-supply for W. A. Clark's proposed new zinc mill, a small flow of artesian water was encountered on the flat near Timbered Butte. This has led to considerable speculation regarding the possibilities of such a supply. The matter has been taken up by the Water Resources branch of the U. S. Geological Survey, which has agreed to send a man to investigate. However, if the Government geologists were correct in interpreting the flat, south of Butte, as the result of sub-aerial decay of the granite, the conditions hardly seem favorable for a dependable supply of artesian water. It is said that contracts have been signed by Eastern capitalists for the reopening of the famous Blue Bird property, west of town. Zinc orebodies will be sought. Activity in this section will give the district a resemblance to the olden days when the silver mines were in operation.

Butte, August 23.

**NEVADA****HUMBOLDT COUNTY**

There has been quite a rush from Lovelock, Inlay, and Mill City to the new find in Inskip canyon, 14 miles from the latter place. The original discovery shows 24 in. of ore which pans from \$75 to \$100 per ton. The district is easy of access and there is good water obtainable.

**LINCOLN COUNTY**

Mining at Pioche is fairly brisk just now. The Prince Consolidated is shipping 300 tons per day; the Mendha company, 50 tons from its property in the Highland district; the Day-Bristol, 100 tons from its Bristol and Jack Rabbit mines; while the Home Run Copper Co. and Highland Mary mine are also sending out a fair tonnage. Besides this ore, over 100 cars of tailing per week are going from Bullionville and Condor canyon, making in all about 200 cars per week over the Pioche branch railroad.

**NYE COUNTY**

At the Big Four rich ore has been found on the hanging wall of the glory-hole. On the 500-ft. level a raise is being made to the 400-ft. in ore which assays \$15 over 5-ft. width. At 75-ft. depth in the Indian Camp property the lode is 12 ft. wide, with variable pannings. The Bath lease shaft is to be sunk from 270-ft. depth. Six feet of good-grade ore is being stoped from the 250-ft. level of the Muskett-Wittenberg lease of the Manhattan Consolidated. Assays return from \$15 to \$38 per ton. The White Caps company is breaking out a good deal of ore which is worth about \$30 per ton from the 75-ft. level.

**STOREY COUNTY**

A Los Angeles company is having a large dredge built in the Carson river, below the sites of the old Morgan and Mexican mills. It is intended to dredge the river channel and recover the gold and silver from the tailing washed into the river during the time the mills were working.

During the week ended August 24, the Mexican mill crushed 515 tons averaging \$26.63 per ton, equal to \$13,714.

WARD SHAFT ON THE COMSTOCK.

The extraction is reported to have been 92%. This ore came from 2400 and 2500-ft. levels. The new compressor for the Union shaft has arrived and will form part of the equipment for this joint shaft and will give additional air needed for work below the 2500-ft. level in Mexican, Union, and Sierra Nevada mines. During last week an attempt was made to short-circuit electric wires at the Mexican mill. A telephone wire near the mill had been cut, and a piece of the wire weighted at both ends with stones had been thrown over the high-tension wire. Fortunately the circuit-breaker in the mill worked properly, or else great damage might have been done. At the Ophir mine the southwest drift on the 2500-ft. level was advanced to 474 ft. in porphyry and quartz of low value. At the mill a tube-mill is being erected. To the Selby smelting plant 45 tons of concentrate from the Kinhead mill was shipped. Its value is estimated at \$30,000. On the 2500-ft. level at the Union mine, in the main gallery, the raise was driven 14 ft. above the sill-floor, showing 24 in. of quartz. Eighteen cars of

ore were saved, averaging \$8.55 per ton. At the C. & C. pumping shaft the centrifugal pump was lowered to the 2500-ft. level for temporary service. This was a big job, but was finished without any trouble. It will take a week to connect and start this pump. The Starret pump, in the Ward shaft, was brought to the surface. It is intended to only keep the water below 2100 ft. in future. This will mean a decrease of \$14,000 per month in expenses.

#### WHITE PINE COUNTY

One of the troubles at the McGill plant of the Steptoe Valley company, in concentrating copper ores, is the tendency of fine mineral to escape with the slime, so a small experimental plant has been fitted up to deal with this loss. The re-pumping system at the Steptoe concentrator is now sending back to the mill over 5000 gal. of water per minute. The walls of the settling ponds are now tight, and the slime will be flushed out by hydraulic pressure. The ponds will then serve their purpose of supplying clear water to the re-pumping plant. Sinking has been stopped at 725-ft. depth in the Zaack shaft of the Ely Consolidated owing to hard formation being met. A station will be cut out at the 700-ft. level, then driving south will be started. An effort is being made by prospective shippers for lower freight rates on low-grade ores from the Ely district to the smelters of Salt Lake valley. The present rate on \$15 ore is \$3.50 per ton. From Pioche to Salt Lake smelters is much farther, yet on \$7.50 ore the rate is \$1.75 per ton. It is claimed that a large quantity of ore would be sent if rates were lowered. The Boston Ely is erecting a boiler and air-compressor. Fifteen claims have been located on the lead belt in Rocco-Hamilton canyon, which are to be developed by a tunnel 300 ft. long and should open the main vein at 350-ft. depth. The water of Illipah creek will be used to generate power, and 250 hp. can be secured. A two-years lease has been taken on the Cuba mine, in the Blaine district, and two carloads of rich galena will be shipped.

### UTAH

#### BEAVER COUNTY

It is said that the Utah mountains have few prospectors about now, and 'conservation' is blamed for this neglect to explore the country. The Majestic mine will ship 40 cars of ore during August, against 28 in July.

#### JUAB COUNTY

The Eagle & Blue Bell mine is looking well. On the 1350-ft. level, 430 ft. was driven, and the face is showing first-class shipping ore. Raising is in progress from the 1350-ft. level to connect with the orebodies opened during the past several months by a series of winzes driven from the previous depth of the shaft. Ore has now been proved from 700 to 1350-ft. depth. The 700-ft. level has supplied a lot of rich ore, and production continues from winzes from the so-called 1000-ft. level. When this and the 1350-ft. level are connected, ore will be broken in a cheap way and the output increased.

#### SALT LAKE COUNTY

The Ohio company's mill dealt with 2700 tons of copper ore in 24 hours at the beginning of last week. Mining men state that there is a shortage of men for work in the Bingham district.

The Bingham-New Haven company at present sends its ores to the Tooele smelter over the Utah Consolidated tramway, but the company now intends to connect with the No. 7 or main working level of the Utah Consolidated, through which ore will be taken instead of over the tramway. About 900 ft. will have to be driven, besides raising, cutting ore-shoots and pockets, the whole to cost about \$18,000. It is expected that the new method of transport will save \$1.50 per ton. The Bingham company is erecting six more vaners in its mill. The Michigan-Utah company, at Alta, has cut a vein below the lower adit-level of the old City Rocks lease, which is part of the property. The lode is from 15 to 18 ft. wide, and contains copper, gold, and silver to

the value of \$80 per ton. Repairs to the tramway are half finished. An automatic loader has been ordered. The company shipped, on August 17, 200 tons of lease ore and 25 tons of company ore, averaging \$40.65 per ton. There are about 500 tons of ore on the dump for shipment.

#### SUMMIT COUNTY

The Silver King Consolidated, at Park City, will increase its capital stock from 500,000 to 700,000 shares of \$1 each. Five mines at Park City shipped 1805 tons of ore for the week ended August 17. It is said that work has been started on a new tunnel on Nigger hill, to tap the Silver King Coalition at a depth of 1300 feet.

In the case of Charlotte Cassidy v. Silver King Coalition Mines Co., the U. S. Circuit Court of Appeals affirmed the ruling of the lower court and assessed the costs against plaintiff. The latter claimed one-fourth interest in the Capital Lodge claim, at Park City. The title is now vested in the Silver King Coalition company.

#### TOOELE COUNTY

At the old Mercur camp, it is said that two mills will be at work very soon. That of the Franklyn leasing interests on the Geyser Mary property is working well, while the Norma mill will be finished in a short time, for that claim.

### WASHINGTON

#### FERRY COUNTY

(Special Correspondence.)—The Spokane section of the A. I. M. E. held an official meeting at Republic, on July 26, and spent three days inspecting the mines and mills of the district. Seventeen members attended the meeting, which was the result of an invitation of the Republic Commercial Club. F. A. Thomson gave some interesting data on the resources and output of the camp. The metallurgist of the Sans Poil mill, E. C. Morse, read a paper on treatment of the Republic district ores, which covered some of the older methods used here. [Full details of the Sans Poil and North Washington Power & Reduction Co.'s mills were given in the *Mining and Scientific Press* of August 24.] He also dealt with the results of experimental work on the ore with fine-grinding and cyanidation. A banquet was given to the visitors at which 150 attended. H. W. Newton, of the North Washington company, came in for a considerable amount of praise for his metallurgical work, and said: "We have not yet completed the first clean-up, but the assays of the heads and tailing of the ore treated from July 10 to 26 show that the former averaged \$7.75 per ton, and the gold extraction is 95.54%, and that of the silver 94.46%, a total extraction of the value being 95.18%." The visitors included E. Jacobs, F. A. Thomson, L. K. Armstrong, I. B. Hammond, J. H. Jones, G. M. Drollinger, W. P. White, G. S. Bailey, E. L. Jones, M. C. Osborn, J. T. Pardee, W. W. Gifford, J. B. Cook, and others.

Republic, August 16.

#### SPOKANE COUNTY

(Special Correspondence.)—Spokane men have discovered a new silver-lead camp in British Columbia, on Treasure mountain, 21 miles north of Tulameen. They report that the Canadian Government promises to build a wagon-road to the mine next spring. N. E. Linsley, a Spokane mining engineer, recently visited the property, while the Granby company has its chief engineer examining the district also. In order to develop oilfields near Shelby, Montana, a group of Spokane men has organized the Shelby Oil Co. with a capital of \$1,000,000. The company owns 160 acres of land, 18 miles north of Shelby, and already has a well 56 ft. deep, where oil has been found. The claim will be worked this fall, as late as weather permits.

Spokane, August 23.

### CANADA

#### BRITISH COLUMBIA

The Granby smelter, at Grand Forks, broke this year's record lately, in treating 25,751 tons of ore in one week, making the total for the year 778,252 tons, and 13,667,500

lb. of blister copper, 395,000 lb. being sent to the refineries last week. Ore production in the Kootenay and Boundary districts was again well above the average and totaled 52,441 tons, and for the year to date is 1,524,600 tons. Smelter receipts last week were 47,161 tons, and for the year 1,372,733 tons. Metal shipments from Trail were 64 tons, valued at \$53,939. The Granby company has two diamond-drills at work in the Phoenix camp. A new wage-scale has been agreed to by the British Columbia Copper Co. and the Greenwood miners' union, based on the price of copper. When the metal is between 16 and 18c. per pound, all men at the Mother Lode and Lone Star mines and the Greenwood smelter will get an advance of 25c. per day over the present scale. When copper is 18c. or more, wages will be again raised 25 cents.

#### COBALT

It has been decided to reopen the Foster mine at once. The Crown Reserve company has declared its thirty-first dividend, amounting to \$88,440, making \$4,402,021 to date; while the McKinley-Darragh has declared one equal to \$224,679, with a total of \$2,830,559 to date. During the week ended August 17, nine mines shipped 334 tons of ore, and four mines 82,449 oz. of silver, 24,630 oz. of this total being from the Dominion Reduction Co., part of which came from Kerr Lake ore.

The rush to the 4000 acres of country thrown open at the Gillies Limit was full of excitement. The night before August 19 was wet, and camp fires loomed up on the hills around. At midnight the place became active, and tents that hid corner stakes which had been set days ago were torn down, unmasking what had been done in secret, in contravention of the mining laws. At two o'clock, most of the staking had been finished, and there was a race for the Haileybury recording office. Every horse, carriage, and automobile was used, even a special train was hired, but the passengers by this time were forestalled by another locator. At the office, prospectors and others had watchers at the door, and these gave place to the former as they arrived from staking out claims. It is said that the big Cobalt companies had prospectors in the district for a week, and a seam of calcite called for extra watching. The whole business of staking claims was done in orderly manner, calling for no police interference. About 2000 men were there to stake less than 200 claims, near the south end of Giroux lake. Those immediately south of A91, 92, 93, and 94, were the claims watched most. The first to reach the recording office was Ben Killoran, who arrived at Haileybury at 1:03 a.m., and at 8:20 a.m., claim A94, much coveted, was given to him, but there is likely to be litigation over it. There were 125 men trying to get into a small office. No finds have yet been announced on the new field.

At the Haileybury recording office 150 claims were recorded for the new district thrown open, this being 25 claims more than the Larder Lake rush. Five applications were filed against No. A94, five for No. 93, and four for No. 91, which had a special train hired for some of the applicants.

#### PORCUPINE

In the raise from the 100-ft. level of the McEneaney mine, the lode is 4 to 6 ft. wide, and shows free gold. This lode has been driven on for 320 ft. at this level. In about 40 days the shaft will be down 400 ft. Excavation for the experimental mill is well under way. No detailed report of the trial shipment of 32 tons of ore to the McGill University has been received so far. At the McIntyre the drift on the 300-ft. level is out 300 ft. on ore about 10 ft. wide. The mill is running full time, and certain improvements are to be made.

#### MEXICO

##### CHIHUAHUA

The Batopilas Mining Co., in a communication to the Mexican Government, gave the following particulars of its operations: It owns 867 hectares of silver-bearing properties, of which it is working on 173 hectares; and 64 hectares of

gold-bearing property which is not being worked, gold contents being irregular and very low. During the past 32 years of operation, the Batopilas company has found only five important bonanzas, so it is seen that, for the exploration of this country a large outlay of capital is necessary. During the past few years, regardless of large expenditures, the company has suffered heavy losses. Since the date of the consolidation of the properties of A. R. Shepherd, the company has only paid one dividend amounting to 1¼%. Work was commenced on the former claims in 1880 by Mr. Shepherd. Silver was then double the price of the present time; and wages now are double what they were then. While Batopilas is rich in silver ores, it is not rich in native silver, as popularly believed. It has developed bonanzas, but these bodies have not been persistent as in other districts. The veins of the district are generally barren, but contain valuable pockets in certain zones. Outside of these deposits, there is little of value. There has been more money invested in the Batopilas mines than they themselves have produced. The ore reserves, as generally understood, may be considered as none. However, there is one in sight which is being mined, and considerable development has been done, and there is every reason to suppose that other valuable deposits will be found. About 350 men are employed by the company at present. The company works the San Antonio mill, which consists of 90 stamps, of 800 lb. each, worked by water-power, and its daily capacity is 150 tons. The company also has the San Miguel plant of 25 stamps of 350 lb. each, in which rich ore and concentrate is treated by amalgamation and cyanide. Annual production has varied during the past 32 years from 300,000 to 1,500,000 oz. silver. The company argues that its business is decreasing on account of increase of wages and salaries, difficulties in communication and transport, and damages suffered, and lack of confidence in the future. The Mexican Government has benefited from the operations of the Batopilas company, and so the company thinks it is entitled to consideration and protection in every way.

#### JALISCO

(Special Correspondence.)—During the period, March 22 to June 16, the mill at the Amparo mine worked 81.2 days, out of a possible run of 84 days, and crushed 20,976 metric tons of dry ore, equal to 258.3 tons per day. The estimated realizable value of the yield was ₧397,674. Working expenses totaled ₧197,205, and development ₧20,390, which left a surplus of ₧180,078. Construction expenses were ₧45,294, reserve of 17,250 tons broken in the mine ₧35,516, ranch improvements and planting cost ₧2889, a total of ₧83,699. There remained ₧96,379 available for distribution by the home office at Philadelphia.

Etzatlán, August 15.

#### SONORA

(Special Correspondence.)—The mills of the Lucky Tiger-Combination company crushed 6046 tons of dry ore during July, the cyanide plant treated 5810 tons of tailing from the mills, and 1829 from the old tailing dump. The plant was shut down for 58 hours on account of lightning breaking insulators on the power-transmission line. The estimated realizable value of bullion produced was \$65,370; from concentrate \$70,850, and from shipping ore \$21,780, a total of \$158,000. Mining, milling, general, marketing ore, and taxes totaled \$86,587, leaving the net profit for the month as \$71,413.

Kansas City, August 20.

The Calumet & Sonora company should soon finish raising its shaft from 525 ft. to the 400-ft. level. At present the monthly production is 300 tons of zinc and copper, and 50 tons of lead concentrate. Only the day shift is being worked at the wet and dry mills. The Cananea-Boston has started sinking a new shaft on its Siempre Viva No. 1 property, which adjoins the Norton denouncement of the Calumet & Sonora company.

The Duluth-Sonora company, which owns considerable mining property in the Cananea district, is to resume operations on October 1.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

LU C. TYLER is in San Francisco.  
S. E. BRETHERTON has gone East.  
EDMUND JUESSEN has gone to Arizona.  
F. L. SIZER has returned from Arizona.  
THOMAS T. READ is in British Columbia.  
GELASIO CAETANI has returned from Colorado.  
B. X. DAWSON is in San Francisco from High Grade.  
F. P. PAUL has returned to Sydney, New South Wales.  
GEORGE W. MAYNARD is examining the Harqua Hala mine.  
J. W. MALCOMSON was at Keokuk and St. Louis this week.

H. M. CROSMAN is now with the Tiro General mine, at Charcas, San Luis Potosi, Mexico.

Y. TSUBOI, of the Fujita Mining Co., is visiting American copper mines and has gone to Butte.

R. S. BOTSFORD has gone from the Bogoslovsk Estate to Pavada to investigate the platinum deposits.

W. R. DOWLING has been elected president of the Chemical, Metallurgical & Mining Society of South Africa.

S. H. BALL, who has been examining the Bogoslovsk copper mine in the northern Urals, has returned to New York.

ROBERT S. LEWIS of Stanford University, has been appointed associate professor of mining in the University of Utah.

WARREN SMITH addressed the Engineers' Club of San Francisco at the luncheon last Tuesday, on 'Opportunities in the Philippines.' Mr. Smith will sail for Manila, September 5.

JAMES SMITH is chief engineer at the Cerro de Pasco. Other changes are the appointment of J. T. GLIDDEN as general foreman of mills and A. E. SWANSON as general auditor, the latter succeeding F. M. LOPER who returns to New York.

## Obituary

JOHN HARPER, one of the pioneer mining engineers on the Comstock Lode, died at San Francisco this week at the age of 76.

FRANCISCO ALFREDO PELLAS, mine owner and one of the active factors in the revival of the Chontales mining district of Nicaragua, died June 12 at Granada, Nicaragua. Mr. Pellas was born in Italy in 1850, and went to Nicaragua in 1874. One of his first mining ventures was the Neptune mine, which he sold to Joe Lapiere, owner of the Bonanza. He reopened the Javali mine at Santo Domingo, and was also reopening the Escandola at the time of his death. He was the organizer, manager, and principal owner of the Nicaragua Sugar Estates, Ltd., known as San Antonia, which is equipped with modern machinery and produces 5000 tons of sugar. He formerly operated the river steamboat line from Greytown to Granada which is now owned by the government. Mr. Pellas leaves a widow, two sons, and a daughter, the youngest son, Silva, being a student at present at Stanford. The older son, Carlos, succeeds his father as head of the various enterprises.

## Silver Prices

Silver suffered a decline of one cent per ounce in the New York market, as a result of the suspension of purchases by the Government of India. It is practically conceded on all sides that the withdrawal of the Indian Government is but a temporary move, made only for the purpose of preventing too rapid an advance in the open market, and though holders of bullion may be forced to carry stocks a little longer than is desired, higher prices are looked for within a reasonable time.

## Market Reports

### LOCAL METAL PRICES

San Francisco August 29.

Antimony.....	11-11½	Quicksilver (flask).....	42.50
Electrolytic Copper.....	18-18½	Tin.....	50-51½
Pig Lead.....	4.90-5.85c	Spelter.....	8-8½
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, August 29.—Copper is still strong and prices are advancing. There is good demand both for home trade and for export. Lead remains firm and is in good demand at higher prices. Spelter is quiet but firm.

Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Aug. 22.....	17.50	4.50	7.10	62½
" 23.....	17.55	4.50	7.15	62½
" 24.....	17.59	4.50	7.15	62½
" 25.....	Sunday.		No market.	
" 26.....	17.59	4.65	7.15	62
" 27.....	17.59	4.65	7.15	61½
" 28.....	17.59	4.65	7.18	61½

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**PRACTICAL METHODS OF SEWAGE DISPOSAL.** By H. N. Ogden and H. B. Cleveland. 128 pp.; ill., index. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$1.50.

This volume deals with disposal of sewage from residences, hotels, and institutions, quite apart from any connection with a city sewage system. The introduction covers the theory of sewage composition, and a summing up of methods of treatment, in an easy style. The problem of sewage treatment consists in removing, on the average, a small quantity of organic matter from a large amount of water, in such a way that no odors are made by the process, and the cost of treatment be reasonable. It is convenient to divide sewage purification into two processes, the preliminary, in which the most common system is sedimentation, by which the larger solids in suspension are allowed to settle in tanks, so that filter beds used later are relieved from the accumulation of that matter; and the finishing process, whereby the tank effluent is discharged into a system of agricultural drains laid just below the surface of the ground for sub-surface irrigation. The settling tanks being of importance, a good deal of space is devoted to their various designs and accessories, while the final disposal of the sewage is dealt with in a practical manner, as irrigation of land by such matter produces effective results. Chapter VII gives estimates of the cost of such installations.

**CENTENARY CELEBRATION OF THE FIRST COMMERCIAL GAS COMPANY.** 174 pp.; Ill. Edited and published by the American Gas Institute, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$2.

This interesting volume contains the papers read at the Franklin Institute, Philadelphia, on April 18 and 19 of this year, it being the occasion of the hundredth anniversary of the introduction of the use of gas as an illuminant. The celebration was given under the auspices of the American Philosophical Society, Franklin Institute, American Chemical Society, and the American Gas Institute.

A chronology of the early development of gas lighting is given, from 1450 B.C., when 'fire-pans' were in use, to the recent lighting of modern cities by that illuminant. Five different gas companies in America lent a large number of pictures and models relating to gas generally, which is called the Historic Loan Exhibition. One framed paper of 1833 is no less than a 'Remonstrance against Gas in Philadelphia.' C. E. Munroe delivered a lecture at the above meeting, on 'By-products in Gas Manufacture.' On such an important subject, the author did well, and the 38 pages covering the matter are crammed full of the chemistry and details of apparatus in recovering such products as tar, ammonia, and cyanogen compounds. The paper is written in an easy style, with no complex chemical formula. 'Commercial and Financial Aspects of the Gas Industry,' was a paper read by G. B. Cortelyou, and should be studied by those people who say electricity will oust gas entirely in time. The U. S. Census shows an increase of 21% in the use of gas in the decade from 1900 to 1910. From 1905 to 1908 sales increased from 117,866,000,000 cu. ft. to 156,909,000,000 cu. ft. A. E. Forstall gave a lecture on the 'Technique of Gas Manufacture,' which must be understood by every gas works superintendent. 'Gas as an Illuminant' was covered by V. R. Lansing, who dealt with burners used in early times to the revolution in the gas-lighting industry by the invention of Auer von Welsbach in 1885, and the burners now in use with high-pressure systems. In these days, when gas is used so much for heating and cooking, the paper on 'The Use of Gas for Heat and Power; The Testing of Gas,' by E. B. Rosa, is of much interest and value.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**NICKEL** coins are to replace the present bronze currency in France, and a company with \$800,000 capital has been formed in Belgium, by French people, to erect works for nickel production.

**COPPER** mines near Huelva, in Spain, where the Rio Tinto is situated, employ about 10,000 laborers, and in 1911 the output was over 1,000,000 tons of pyrite and 17,657 tons of copper ingots.

**SHOVELING** contests at the Continental zinc mine, at Joplin, resulted in the winner filling 235 cars, each holding 2700 lb., in five and a half days, equal to 317 tons. Eighteen cents per car is paid for this work.

**CAM-SHAFTS**, only two in all, have been broken at the City Deep mill on the Rand, this small number being due to the Laschinger patented cam supports, in which the shafts have a bearing between each cam.

**A PLATE-HOUSE** at the Consolidated Langlaagte contains 40 copper plates, each 63 by 48 in., four to each tube-mill. From the tube-mill and the clean-up rooms there is only one entrance for each into the plate-house.

**CLASSIFYING** diaphragm cones, nine in all, have been erected at the new mill of the Consolidated Langlaagte mine on the Rand, and it is estimated that, after a series of classifiers and tube-mills, the mill-pulp will produce 60% slime and 40% sand.

**STAMPS** at the Consolidated Langlaagte will weigh 1900 lb. each, and one motor drives two 5-stamp cam-shafts. The cam-shaft floor has an iron grating similar to floors in an engine-room of a steamer, in front of the cam-shafts. This should let light on to the lower floor, and allow of easy lifting of spares from floor to floor.

**WAREHOUSE** trucks can be used to advantage by prospectors to wheel buckets of ore or waste to the bottom of a shaft, and have been so employed by William Chalmers at Mazuma, Nevada. They are considered to be better than wheelbarrows, as workings may be narrower, and the buckets are brought right up to the heaps to be loaded. The truck is also easier to handle than a barrow. The ground in a cross-cut or drive would have to be dry for this type of conveyance.

**THE IRON PILLAR** at Delhi, India, is of much interest. It was made about 413 A.D. and moved to its present site in 1052. It is of solid wrought iron and is 23 ft. high, 16 in. diameter at its base and 12 in. at the top, and weighs 6 tons. Samples procured by R. Hadfield, of Sheffield, England, showed the pillar to be of the following analysis: C, 0.080%; Si, 0.046; S, 0.006; P, 0.114; and Fe, 99.720, equal to 99.966%. Its specific gravity is 7.81. Probably charcoal was used as fuel in the manufacture of the iron, while the absence of manganese is noticeable.

**TRANSPORT** of calcium-cyanamide and ferro-silicon involves danger. As the result of an explosion of the former compound on a Norwegian steamer recently, new rules have been issued for its carriage on Norwegian ships. Where the material contains over 0.10% carbide it must, until further notice, be transported in water-tight containers of galvanized iron, of a thickness of at least 0.6 mm. Special precautions are to be taken against dampness while being stowed. Holds must be well ventilated, and only safety lamps used. Calcium-cyanamide containing less than 0.10% carbide is dealt with under other rules.

## Keller Analytical Balance

For about a generation precision balances for assay and analytical purposes were made practically without changes in design or relative fineness until G. P. Keller converted the assay balance into what is known as the 'Keller type assay balance,' which is being much imitated by balance manufacturers in this country. In recent years Mr. Keller devoted much time to designing an analytical high-grade balance that should not lack any of the good points embodied in his assay balance, and stimulated by an enquiry from the U. S. Bureau of Weights and Measures for just such an instrument, continued the efforts that resulted in the analytical balance illustrated in the accompanying figure. The tests made with this new type surpassed all expectation; the first one completed was accepted by the bureau at Washington, and it is claimed there is not an analytical balance on the market its equal for accuracy, speed, convenience in manipulation, and perfect freedom from jarring of the beam (commonly called 'kicking').

The points of superiority claimed for the Keller analytical balance are: (1) The beam is mounted on its support by a new method; each end of centre edge being provided with a screw inserted vertically, one resting on a

V-post, the other on a conically apertured post. This fixes the beam on its support with no lost motion, and whenever necessary it can be readjusted by the operator simply turning one of the screws until the edge resumes its parallel position with its bearings. (2) The release of the beam without any 'kicking' constitutes a saving of time to the operator. The Keller flat stone stirrup balances were the first balances made that placed hangers on the beam before releasing the same, thereby eliminating all jars caused by the hangers. Stirrups, beam, and hanger supports are operated by one knob in front. (3) The Keller stirrups are made mechanically so accurate as to be completely interchangeable. These interchangeable stirrups make possible eight tests on bearing surface of stirrups and keenness of end edges, to determine fractional resistance. If bearing stones and end edges are absolutely correct, the beam will show no variations on pointer scale. (4) Hangers are of a new type, weighing about two-thirds less than any other hanger in use, when sufficiently strong for a load of 500 grams, adding to the rapidity of the balance's action. (5) Hanger supports are of a new style, well appreciated by all users of the balance; they will turn up against the column when it is desired to clean the black plate sub-base and are easily adjusted to keep hangers from swinging. (6) Construction is such that the entire instrument can be thoroughly cleaned, even by inexperienced hands, without suffering the loss of any adjustment, parts being easily and quickly removable and as readily replaced. (7) The superior methods used in producing and assembling parts, resulting from 18 years experience in designing and adjusting precision balances exclusively, all of which tend to prolong the life and delicacy of the finished product. The development of such methods involves the construction of many special machines, superseding the old-time mechanic peculiar to this line,

and has brought the art of balance building to the plane of a profession as intricate in mechanical methods as those of the modern watch or typewriter factory. Formerly a balance-maker drilled holes into glass with a hand brace and steel drill, often spending a whole day on a few holes in one plate, only to break this before completion of the job—and this not more than twenty years ago. This work is now done with diamond tools much more accurately; but these tools had to be evolved for the purpose. Agates were formerly imported from Europe cut 'close to size,' and the metal worked to match the stones; now agates are cut and ground at the Keller Mfg. Co., of Salt Lake City, Utah, to exact size with diamond tools, to fit places provided for them, and plenty of agates are found at home to make good knife edges and bearings. Numerous comparisons between old and modern methods may be cited, of equal moment to the user and the builder of a fine balance—ultimate excellence.

## A Test of Lubricants

One of the most difficult things to buy is a lubricant. The greatest part of the difficulty, however, is caused by the statements of the various concerns engaged in selling lubricants. They all claim their lubricant possesses no bad features—that it is perfect. Every one of them will say that the other fellow's lubricant is full of impurities. The main thing to secure in any lubricant is the greatest amount of lubrication at the lowest cost. A simple but good and practical test is suggested by Adam Cook's Sons, of New York, makers of Albany grease.

Securing an 'Albany Grease' spindle cup, place it on the engine, shafting, or machinery upon which the test is to be conducted, but be sure the cup is thoroughly cleaned before it is used in the test. Fill the cup with a known quantity of Albany grease, then place it in operation. The first thing that will be noted is the small quantity that will be used each day. The reason for this is that Albany grease has a low melting point and runs only when it is needed. The spindle of the grease cup is made of soft copper and rests on the shaft. As the shaft revolves, the conductivity of the copper spindle causes the Albany grease that is packed around it to flow. When the shaft is not in motion the spindle is not heated and naturally the grease does not soften and flow. This condition produces the maximum amount of economy.

There is another way to learn its great economy, and more than anything else its fine lubricating qualities. After the cup has been in service for some time it will be noticed that there is nothing left in it. The Albany grease has all been used and no residue is left. Where there is no waste it means that everything bought can be used, and used with good results. Albany grease is all lubricant—no waste. There are no acids, resin, resinous oils, talc, lime soaps, or foreign substances that eat the bearings, gum up, clog, and create friction instead of reducing it. This can easily be determined by the appearance of the cup and the bearings. They show up as fine as the day they were made.

## Commercial Paragraphs

The DODGE MANUFACTURING CO., Mishawaka, Indiana, has just received an order from the American Boston Mining Co., Clowry, Michigan, for twelve line-shafts equipped with chain oiling ball and socket pillow blocks.

The G. P. KELLER MFG. CO., Salt Lake City, Utah, maker of the 'Keller' assay and analytical balances, has opened a department for the repair and adjustment of engineers' instruments, transits, and levels, in charge of Gustav Warkentin, head of the firm of Warkentin & Krause, Leipzig, Germany, an expert in this line.

SALARIES and wages earned at Transvaal mines in 1911 totaled \$71,350,000.

## EDITORIAL

REPORTS indicate that the fall meeting of the Lake Superior Mining Institute was fully up to expectations in attendance and interest. We will present later some of the papers read.

CRIPPLE CREEK operators are so well pleased with the results of the Roosevelt deep drainage adit that a movement is already being organized for the driving of a still deeper adit. Since it is estimated that five years will be needed to complete the work economically, it will be well to begin promptly.

CAMP BIRD has again come to the front, this time with the discovery of an 11-foot vein, 60 feet from the shaft on the 500-foot level. The vein contains lead sulphide, and samples are said to assay as high as 5 ounces to the ton. Sinking is to be resumed and an effort will be made to reach the vein on the 600-foot level.

GUADALAJARA, one of the most beautiful and interesting cities in Mexico, has been repeatedly injured by earthquakes. Now the announcement is made that the city must be abandoned, as it is built on the site of an impending volcano. The evidence upon which this prediction is based is not at hand, and all lovers of the old city will hope that when thoroughly examined it may not point to any such fatality as now predicted.

PUBLIC opinion is all powerful in the United States when brought into play, and as *Harper's Weekly* points out, modification of the Panama canal bill in conference so as to permit all ships in foreign trade equal rights, was a distinct triumph of the best public opinion. In the *Century* for September American sentiment is reflected in an article on "Can a Nation be a Gentleman?" The sentiments that "the greatest service our rulers at Washington can do the country is to see that its honor is kept as untarnished as that of the most scrupulous gentleman," and "the way to make a people love their country is to make sure that its reputation is maintained as a source of love and pride," will meet universal approbation.

WESTERN AUSTRALIA is about to join her sister states in opening a university. Among the members of the Senate of the new institution is Mr. G. M. Roberts, the accomplished general manager for the Associated Northern Blocks (W. A.), Ltd. Thanks largely to his foresight and energy, mining will be appropriately provided for in the new school. Aside from the chair of agriculture, which is separately endowed, it has been resolved that there shall be chairs of mathematics and physics, mining and engineering, history and economics, English, chemistry, and geology. As there are already adequate facilities for secondary instruction, the university is to give only advanced courses. The professors are each to receive \$4000 per year, with an allowance of \$500 for house rent, and there will be the usual complement of lecturers, demonstrators, and assistants. The new school will open its doors at Perth in March 1913 and would seem to be assured of every success.

**I**MPORTANT changes in the mining laws as applicable to Alaska are summarized this week in our department of 'Decisions Relating to Mining.' Another notable change made by the last Congress was the granting of local government to the Territory and the establishment of a Railway Commission to report upon routes suitable for building. Upon the latter commission is to be placed, among others, an officer from the Geological Survey. No final action regarding the coal lands was taken.

**I**LLINOIS geologists keep up their good work of furnishing prompt information to the oil men concerning the geological structure of the state, and the oil men reciprocate by giving the geologists free access to all records. This co-operation has already resulted in discovery of several outlying fields and is sure to greatly simplify the problem of finding the deeply buried sands. Bulletin No. 20 of the State Geological Survey, prepared by Messrs. E. W. Shaw and Fred H. Kay in co-operation with the United States Geological Survey, treats the Carlyle and Carlinville fields and is an excellent illustration of how an official survey can help private industry.

**F**EW recent decisions of the General Land Office have created as much discussion among mining men as has that in the East Tintic case. We are especially glad, therefore, to present this week a full review of it. From the letter of Mr. Samuel C. Adams, it is evident that the Department rested its finding on the facts in the case; namely, that the defendant did not in fact make a discovery on the ground in question that would warrant a reasonably prudent man spending money for development. This is the old rule, and is very different from a requirement that commercial ore be found as a prerequisite to patent. It was the same rule laid down by the courts, in that case to the loss of the Government, that land could not be held to be coal land, and therefore entry as agricultural land did not constitute fraud, except when an actual discovery of coal had been made on the ground. This we have always believed to be foolish. In other words, we believe that the evidence of geological structure may be quite as reliable as the stripping of a thin bed of bituminous matter, such as has often been held to constitute a discovery of coal. In the East Tintic case the land was desired because of the presumable presence under it of an extension of an orebody outcropping on adjacent ground. Without knowing the details of the case, one may still be safe in affirming that such evidence might well be strong enough to warrant a prudent man investing money. The land was not, however, claimed upon this ground, but upon the presence of an admittedly worthless vein. We believe the decision was sound. The remedy was for the claimant to sink or otherwise expose the ore of real or probable value, unless extralateral rights prevented his claiming it. If so, under present law, he should not have been given the land. Back of it all, however, we hold that the requirement of a discovery should be stricken out of the law. In the days when only ore outcropping at the surface entered into calculations, the requirement was reasonable. Now it is not. Every practical miner knows of excellent orebodies that do not outcrop, and the development of geologic science has been such that the old rule regarding discovery has become a farce. In our opinion it is better to meet such issues squarely and to amend the law than to abuse officials for not making a 'liberal construction.' The trouble with liberal constructions is that they make the courts legislative instead of judicial in character. The sounder practice is to amend the law.

## Mexico and Nicaragua

New interest has been given the Monroe doctrine by recent events in more than one quarter of America. Señor Don Perez Triana, editor of *Hispana*, has proposed to the several Latin American republics a radical extension of the doctrine, one of particular import just now. It will be remembered that the Monroe doctrine was designed to prevent European intervention in America for purposes of oppression or the "controlling in any other manner" of the destiny of an American republic. While European nations have never recognized the doctrine they have respected it. Señor Triana now proposes that "the exclusion of conquest of territory, as a fundamental principle of international life on the American continent should be solemnly proclaimed by all the American nations; they should all pledge themselves to maintain it." This would practically promise international maintenance of the present status, which in the future might or might not, prove wise.

Mr. F. B. Loomis, replying for the United States, observes that "as the United States does not covet an inch of foreign territory in the new world, I see no reason why this country should not subscribe to the proposed declaration." Mr. Loomis undoubtedly correctly reflects American opinion in the first part of this statement, whether or not all would endorse the conclusion. There are many people familiar with the affairs in Central America for example, who think it inevitable that the United States will in time exercise larger control over affairs in Latin America; but even these, so far as we know them, dread the contingency. Nothing would please thoughtful citizens of the United States more than to see every American republic enjoy strong and stable government. Unfortunately, in the case of certain communities, that seems now far away. The United States has troubles enough without annexing more, and extension of our territories is far from being an American ambition now, whatever may have been true in the past. With a large share of the white man's burden already on our shoulders, the glory of raising the flag on foreign shores makes but scant appeal. The rôle rather of helpful, sympathetic, elder brother is the one that is in the public mind. A firm declaration that the United States has no ambitions in the line of conquest, would be propitious, and would but put into words the present thought of the people.

All this, however, does not mean that we have no duties and are to cling fatuously to a policy of non-interference. The United States has repeatedly interfered in Central America to prevent useless sacrifice of right and property. The people of any country are entitled to what government they wish, but they are not entitled to destroy the lives and property of the 'innocent bystander' save in the gravest emergency. American marines are now in control in Nicaragua and regular troops may be sent there at any time. The right to intervene in such a situation as obtains there is merely the right to protect life and property when the local government fails. Whether one party or the other to the contest in progress wins is no concern of ours. The position of our troops may incidentally help or hinder one side; that is unfortunate but unavoidable. Except in the size of the expedition, the action of the Government in landing the marines in Nicaragua is not unusual. It would call for no special comment were it not for the present critical condition of affairs in several of the states of Mexico. From the first we have maintained that it was for the Mexicans to settle their own difficulties, and that so long as organized civil war was being conducted we must patiently await the outcome. The situation has now taken on another phase, and we believe the time has come for the

United States Government to quit talking and to act. There is nothing in the situation justifying sending American marines to Managua that will not also justify protecting El Tigre and Cananea from robbery by bandits. It is a mere accident of geography that a land rather than water boundary separates Sonora and Arizona, and this should not influence a question of right. There is little doubt that if necessary the United States could and would land marines to protect Guaymas if seriously threatened by Orozco and his men. There is also little doubt that indirectly, by making its possession valueless, the United States forced the evacuation of Juarez by the rebels. It appears to us that too much attention is devoted to technical position and too little to facts.

When some years ago the Apaches were ravaging the border, Mexico and the United States quickly came to an agreement permitting the troops of either to follow the enemy into the territory of the other; and whether one be killed by an Apache or a drunken Mexican rebel makes little difference in the end. The rebels are now hopelessly defeated in open warfare. All they can do is to needlessly prolong a guerrilla campaign that has already descended to brigandage and been stained by practical savagery. For the United States to permit large and prosperous towns and works, owned and operated by her own citizens, to be held up and ravaged by roving bands of brigands is disgraceful. We cannot believe that intervention in such a case, which is radically different from mixing into a family quarrel, or attempting the conquest of a state, would be other than welcome to Mexico and the Mexicans.

### American Mining Congress

The official call for the fifteenth annual session of the American Mining Congress, to be held at Spokane, Washington, November 25 to 28, inclusive, has been issued. It is a document well worth reading, and, whether we agree or disagree with the viewpoint of the committee issuing it, there can be little question that the topics proposed for discussion are of direct interest to mining men. The Congress takes as its watchword, safety, efficiency, and conservation; and it recognizes coöperation as the means necessary to accomplishment. It proposes thorough discussion and deliberation as the best means of bringing about a better coöperation in production and distribution, and it has been successful in the Eastern and Middle Western states in securing the support of both operators and men. In the West support comes mainly from the operators of the smaller mines, though a number of the chiefs of large enterprises have been enlisted. The gulf between the leading operators and organized labor in Western metal mines has proved too wide to be bridged, and in part because of the lack of a common forum for discussion, there are sharper differences in opinion, even among mine operators, in the West than in the East. The Mining Congress, for example, is committed to the doctrine of workmen's compensation for accidents, and has exerted powerful influence toward its enactment into law in several Eastern states. The chairman of its committee on this subject is one of the leading coal operators in Pennsylvania and among the members of the committee are several powerful in the councils of the United Mine Workers of America. The official call speaks of employers' liability as "barbarous." Western sentiment regarding this matter is still profoundly divided, and if there are arguments that appear sound at once to the hard-headed operator in a competitive industry, and to the radical labor leader, if a law can be framed that is satisfactory to both, evidently the West needs enlightenment. No one sees another suffer hardship except with regret, and if the Mining Congress has found a better way to

distribute the burden of sorrow incident to mining, its message will be welcomed by its early friends throughout the West.

Control of trusts, regulation of competition, and amendment of the Sherman law, are subjects of interest not alone to mining men, though in the coal industry the need of change is peculiarly acute. The appropriate committee of the Congress has proposed an Interstate Trade Commission, and this is in line with much of the best thought on the subject. Public opinion has not fully endorsed this plan, and a full presentation of its advantages and drawbacks will be of great service. As to conservation, the official call points out that this is a fundamental question affecting not alone Alaska or the public-land states, but the whole country. Increased safety is bound to come as fast as engineers provide the means and public attention is focused upon the need, but diminution of waste is another matter. Gradual improvement is to be expected, but whether the present generation will support drastic legislation which, while preserving material from waste, increases present costs, is not so certain. As to the public lands, the call indicates strong leanings toward state control, and here again opinion is divided and full frank discussion is essential to any right decision. Mine taxation, another problem proposed for discussion, is one that is well worthy of attention. It will come as a surprise to many to know that in many Western states the taxes upon a mine are based upon the total amount that it may reasonably be expected to produce during its lifetime, plus an acreage tax. Into the intricacies of mine assessment and taxation few have penetrated. Most men are content merely to secure some reduction or not to pay more than some neighbor. How the assessment on a mine compares with that on a farm, a bank, or a railroad, is rarely discussed. Taxes in any one year form but a minor item in the accounts of any successful mining company, and it is apt to be forgotten that output, in the case of mines, is division of principal as well as profit.

In Alaskan matters the American Mining Congress has been particularly active, and at the Spokane meeting Alaskan problems are expected to be especially prominent. Indeed, the meeting was set late in the year so as to assure a large attendance from the Far North. Under the guidance of an able committee, the Mining Congress has formulated and urged upon Congress at Washington bills providing for railway construction and the opening of the coal lands. Neither bill was passed, but there can be no doubt that much progress was made in the direction of agreement and the framing of a law that may be expected ultimately to be enacted. Abandoning useless opposition to the policy of the present Administration, fortified as it is in these particulars by a strong public sentiment in the East, the Alaskan committee wisely devoted itself to the details of the proposed bills and to shaping them as nearly as possible in agreement with sentiment at home. We have already discussed the proposed measures, and, recognizing that any legislation on such disputed matters must be a compromise, we heartily endorse them. If the meeting at Spokane does nothing more than to bring to bear such public sentiment as will assure their prompt passage, it will have accomplished more to open Alaska than any other one thing. On the whole, an excellent program has been laid out, and with such men as Messrs. S. A. Taylor, D. W. Brunton, Carl Scholz, James Douglas, and E. A. Colburn, and the hard-working secretary, Mr. J. F. Callbreath, and with an active local committee, in control, a profoundly useful meeting seems certain.

## Steel Sets in Inclined Shafts

By WALTER LYMAN BROWN

In the Tarquah district of the Gold Coast, of South Africa, steel has of late almost entirely supplanted timber for shaft sets, main stations, and loading bins as well as for practically all important surface constructions. This is due to the excessive deterioration of timber caused by the hot moist climate, which is further accentuated on the surface by the ravages of the white ants. Certain of the native timbers, especially *kako*, have a fairly long life, but they are heavy and hard, difficult to shape and frame, and are short grained. They sustain compressor loads well, but offer practically no resistance to bending, and are therefore of little avail for caps, though they can be used for posts

dividers and end plates to the sill and foot-wall of the shaft, and the other along the line of the shaft, through the studdles or distance pieces to the bearers. The latter becomes especially prominent when the hanging is very heavy and loose, and to resist this component of the weight I consider the cap to be of too high and narrow a section. A girder of the same weight, but with an approximately square section, would resist this force better and would offer very little resistance to downward pressure. The tendency of this force acting along the line of the shaft, is to bend the caps between the studdles along this line, and to cause a slight 'creep' of the lagging on the caps which causes them

FIG. 1. DETAIL OF ABBONTIAKOON FRAMING.

FIG. 2. DETAIL OF ABBONTIAKOON FRAMING.

and sills. *Kako* makes excellent blocking and wedges, and is largely used with steel for this purpose. Mahogany is a lighter wood, more easily worked, and is used a good deal for flooring, but has very little strength. Imported timber from Oregon and Norway was mainly used when the shafts were first sunk, but was found to have such a short life that its use was discontinued by most of the mines, and steel sets were substituted with excellent results. In some cases imported timber which have been in shafts for

to bend on the web. In the Abbontiakoon main shaft, where, in replacing timber sets with steel, a section of ground was gone through that had a very heavy hanging wall, requiring false sets and driving of the lagging, in several instances caps were bent in the web through arcs of at least  $30^\circ$ . This could, to a certain extent at least, be improved by using caps of a squarer section and shorter and thicker web.

All sets are put in with a batter up the shaft of approximately 6 in., that is, the cap is some 6 in. farther up the shaft than the sill, measured from a line at right angles to the incline of the shaft. All sets, where there is any weight on them, tend to 'ride' down the shaft, this tendency being resisted by the bearers. Putting in the sets looking up the shaft, partly counteracts this 'ride,' as the caps swing through an arc whose radius is the height of the sets, and whose centre is the bottom of the sill, which is in a fixed position. Sets thus placed, therefore, in order to ride, must first force up the weight of the hanging wall supported by them. Sets put in at right angles to the incline are only kept from riding by the bearers, and in practice these are usually not entirely effective, and when a set has passed the right angle and is looking down the shaft, even to a very slight degree, its value as a support to the hanging is greatly lessened.

Blocking is done in the manner customary with timber sets, namely; at the four corners, both top, sides, and bottom, and above and below each divider. The native timber *kako*, is largely used for this purpose. Sills are often placed on small concrete pillars, the sills being imbedded to about half their depth in the concrete. This is done more especially near the surface, where the ground is apt not to be as hard and firm as it is at greater depths. In one instance, sets are carried for some distance on three continuous concrete piers, running up and down the shaft.

Rails are bolted to the sills, through holes drilled in the

not to exceed two or three years could be almost torn apart with a candle-stick.

Fig. 1 to 8 illustrate types of shaft-sets used, figures 1 to 7 show that of the Abbontiakoon mines, and Fig. 8 of the Fanti mines. These are both subsidiary companies of the Fanti Consolidated group. These figures show the shapes and dimensions of girders used and the method of framing and of joining the members of the sets. All joints are made with bolts, so that they can easily be put together underground. These sets on the whole are satisfactory. Their life is practically indefinite, and they withstand all ordinary strains thrown on them very well. In inclined shafts, however, the pressure from the hanging wall is resisted by forces acting in two planes; one at right angles to the shaft, carrying the weight through the

FIG. 4. GENERAL ARRANGEMENT OF FRAMING.

FIG. 5. HORIZONTAL BEARER AT ABBONTIAKOOK MINE.

FIG. 6. UPRIGHT BEARERS, ABBONTIAKOOK MINE.

FIG. 7. GENERAL PLAN OF ABBONTIA-KOON FRAMING.

flanges of each. The sills are drilled to template in the shops and the rails are drilled in position in the shaft with hand ratchets or pneumatic drills. This gives excellent results, insuring rigidity, and entirely prevents any slipping of the rails which so often happens in inclined shafts. Bell and power cables are also bolted by means of clips to the sets.

Bearers are put in at varying intervals, depending on the ground, of 50 to 100 ft., though 60 to 80 ft. is the most

common distance. In the heavy ground in the Abbontia-koon shaft, previously referred to, they have been put in as close as 30 ft. apart, but this was an exceptional case. The class of bearer used also depends on the nature of the rock. In ground with a firm or fairly firm hanging wall the ordinary 'upright' bearer, so called in distinction to the horizontal or longitudinal bearer, is used. This is the type commonly used in all shafts, well hitched into both foot and hanging, with the lead into the upper side of the hanging

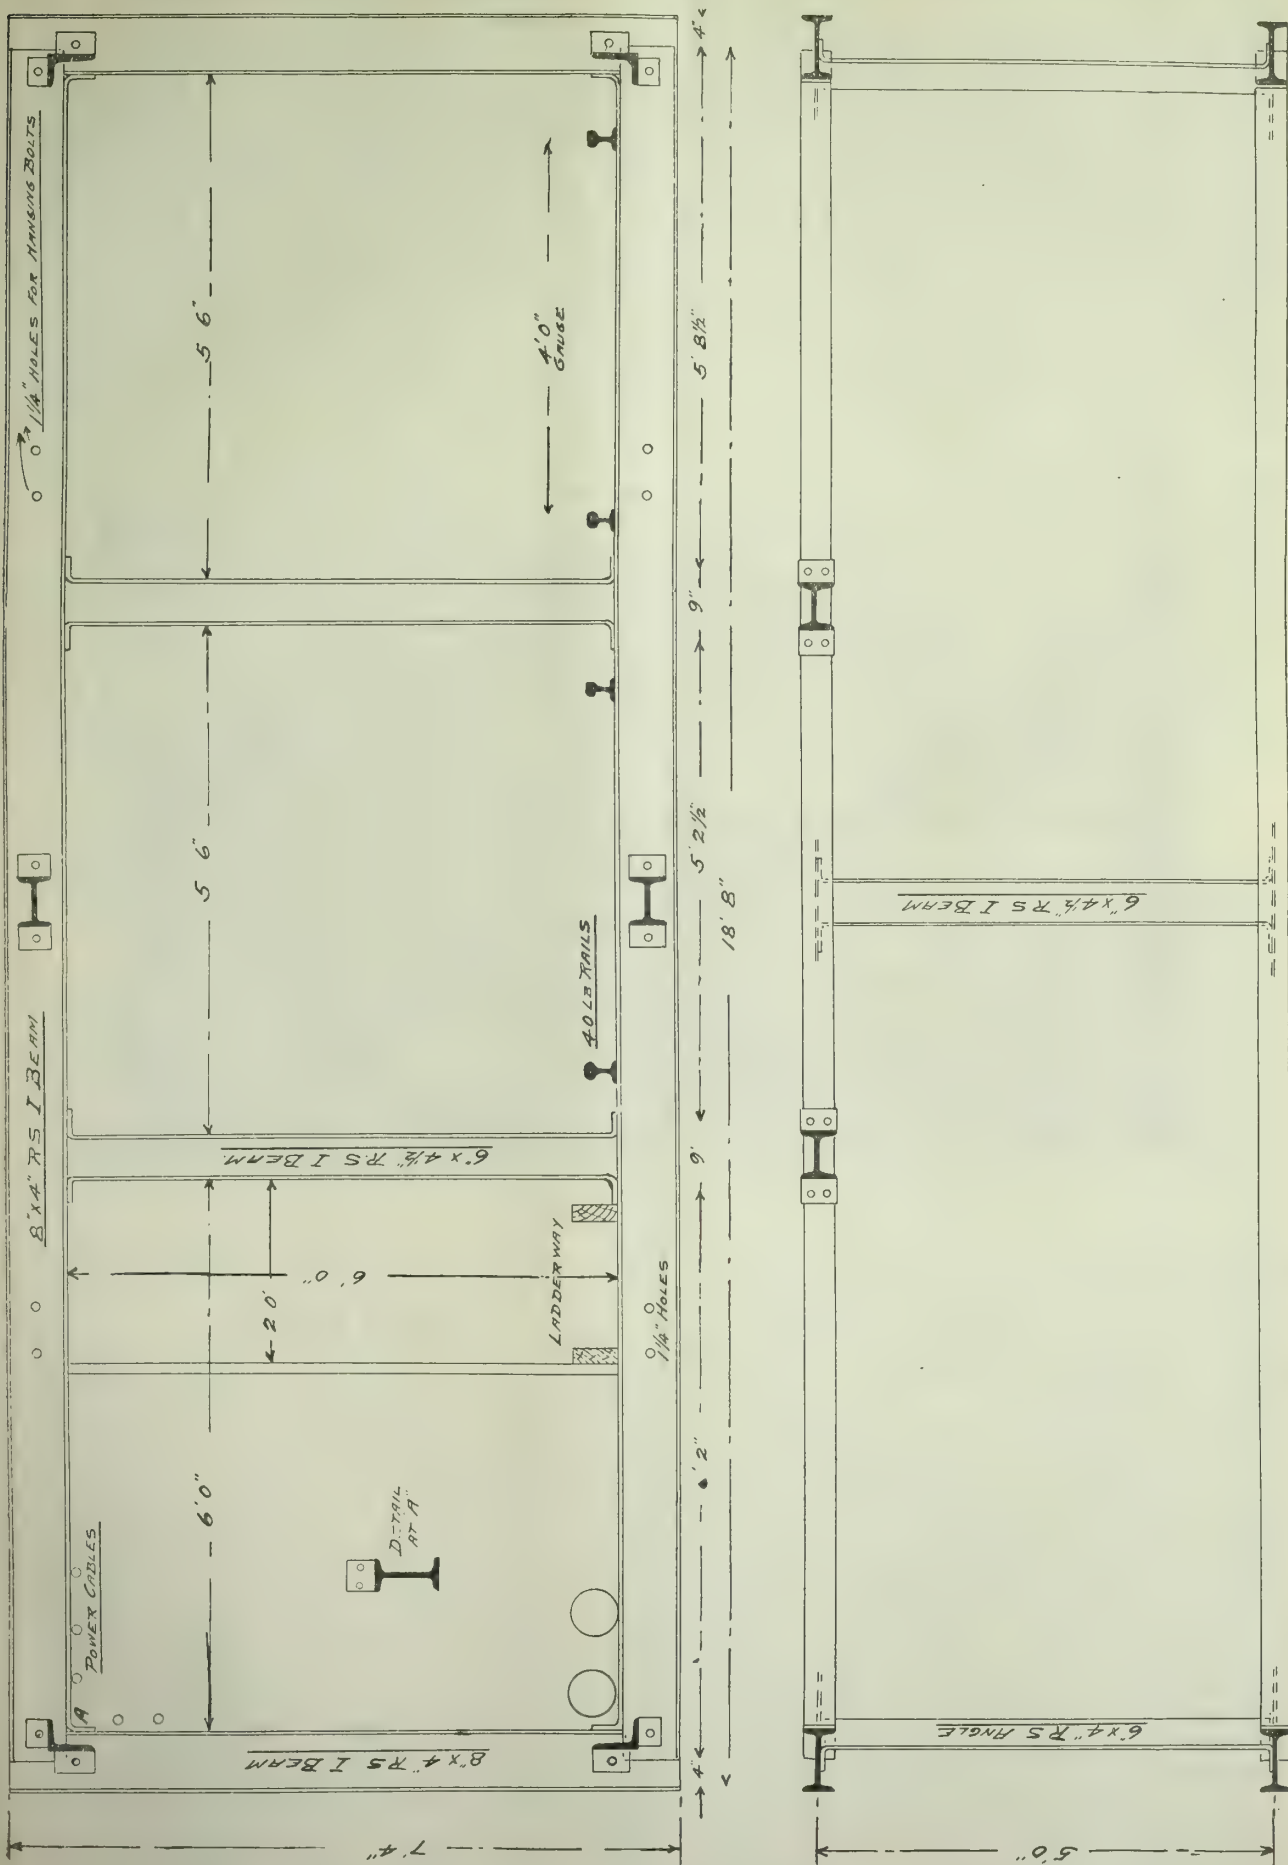

FIG. 8. STEEL-FRAMING AT THE FANTI MINE.

wall hitch, and with the bearer firmly concreted into its place. Usually three bearers are put in to each set, one below each end-plate and one below the centre divider, and they are usually I-beams of about 6 by 10-in. section.

Where the hanging wall is not sufficiently firm to afford a secure hold for upright bearers, horizontal bearers must be used. These, as used in the Abbontiakoon shaft are 6 by 16-in. steel I-beams (see Fig. 5), spliced in the centre. Splicing is necessary, as, from the nature of the ground, the sets must be kept close to the face, allowing no room for leading the bearers into hitches. A lap-joint is used, with plates on each flange and on both sides of the web of the girder, all being drilled to template in the shops and put together in the shaft with bolts. Hitches are cut deep with bearers of this class, as the ground is apt to be weak, and they are firmly concreted into position. In addition, braces of 6 by 16-in. I-beams are put in as shown in Fig. 5, these being cut at the top to the shape of the bearer and firmly hitched and concreted into the foot-wall. In spite of the strong girders used, both as bearers and braces, in one shaft with heavy hanging wall, it is not uncommon to see the bearers bent several inches down the shaft by the riding due to the vertical component of the weight, previously referred to. Horizontal bearers are not allowed to take any down weight, as they are set the wrong way and are not supported to withstand it. All bearers are so placed as to give the sets the batter up the shaft previously mentioned. Corrugated steel sheets have been used with good results as top lagging, where driving is not required. They are held in position by S-shaped clips hooked over the caps. They are not very satisfactory for side lagging.

## Testing Roasted Ore

The aim in roasting is to obtain a product having a minimum quantity of oxygen-absorbing salts, such as soluble sulphites and sulphides occurring as calcium sulphite and ferrous sulphide (FeS), respectively. This reducing effect is estimated by titrating a caustic soda extract of the ore with N/100 iodine solution, and as a rough quantitative test for purposes of daily comparison it is found to be extremely valuable. The method of testing, using the following standard solutions, (a) water solution of NaOH containing 60 gm. to the Winchester gallon, and (b) N/100 iodine, is as follows: Twenty grams of each of the roasts to be tested are weighed into a like number of 8-oz. conical beakers. A sufficient quantity of the NaOH solution is brought to boiling in a separate vessel, and 100 c.c. of this boiling solution is measured off into each beaker. The assays are placed on a hot sand-bath, brought again to a boil, and kept boiling for a minute. They are then removed, allowed to settle, and 50 c.c. of clear solution pipetted off. Phenolphthalein and starch solution are added as indicators; the assays are acidified with dilute  $H_2SO_4$  and titrated to a faint blue with N/100 iodine.

In the case of estimating reducing agents other than sulphides, a few cubic centimetres of ammoniacal zinc chloride solution are added to the NaOH solution before beginning the test. This solution is then boiled, 100 c.c. measured off, and the test performed exactly as before. Any ZnS precipitated by the ZnCl<sub>2</sub> in ammoniacal solution is carried down by the ore, and the clear solution pipetted off contains no sulphides. Experience with Kalgoorlie ore has shown that, when the test does not much exceed 4 to 5 c.c. of N/100 iodine, the result is generally a good extraction of the gold, with a normal consumption of cyanide. Calcium sulphide is the chief reducing agent, but when the test is more than 4.5 c.c., it is usually indicative of the presence of ferrous sulphide also. This may be detected by adding an emulsion of PbCO<sub>3</sub> to a NaOH extract of the ore, when a brownish precipitate of PbS will be formed. The occasional presence of ferrous sulphide does not affect extraction materially; but, when excessive in quantity and persistent, the strength of the cyanide drops greatly, and the residue rises in value to an appreciable extent.

## Mining on the Gold Coast

An interesting report on the mining industry of the Gold Coast for the year 1911 has been issued by the Government, from which it appears that the value of gold produced was nearly £1,079,024, being an increase of £298,626 as compared with the value of the gold produced during 1910, and is the largest production since the year 1908. In the Gold Coast Colony the increase amounted to £171,048, and in Ashanti the increase was £127,578. The increase in the Gold Coast Colony was due to the Prestea Block A and the Broomassie Mines restarting to produce gold, and the increase in Ashanti is totally due to the enlarged production by the Ashanti Goldfields Corporation. The total number of ounces of fine gold obtained was 253,977, of which 238,571 oz. was by mining and 15,406 oz. by dredging operations in the Ankobra, Fura, and Offin rivers.

From the conglomerate mines 91,802 tons of 2000 lb. was crushed and treated, producing 44,233 oz. of fine gold, being an extraction of 9.64 dwt. per ton crushed; while from the quartz mines 359,990 tons was treated, producing 194,289 oz., giving an extraction of 10.79 dwt. per ton treated. By sluicing, 49 oz. was obtained. The various dredging companies treated 2,545,173 cu. yd. of alluvium, with a production of 15,405 oz. of fine gold, being an extraction of 2.90 gr. per cubic yard treated. The only other mineral prospected for besides gold was mineral oil, near Bonnyere, in the Western Province, where the Société Française de Pétrole (a British company) was engaged in boring. The average daily amount of labor employed by the mining and dredging companies throughout the year was 19,153, as compared with 19,138 employed in 1910. There was no apparent shortage of labor in the mining districts; but toward the end of the year several mining companies started to introduce labor from other colonies to meet the anticipated requirements for the year 1912.

### YEARLY OUTPUT OF GOLD FROM 1892 TO 1911.

## Uses of Feldspar

The principal use of feldspar is in the manufacture of pottery, enamelware, enamel brick, and electrical ware. Of these the most important is its use in the body and glaze of pottery and vitrified sanitary ware, in which it constitutes 10 to 35%. Its value in pottery lies in the fact that it melts at a lower point than the other ingredients and serves as a flux, binding the clay and quartz particles together. In glazes the percentage of feldspar used is higher than in the body and runs 30 to 50%. Other uses of feldspar, which do not require the high grade demanded by the pottery trade, are in the manufacture of emery and corundum wheels, where it serves as a flux; in the manufacture of opalescent glass; as a poultry grit; as a constituent of roofing material; and as ballast. Small quantities of the purest grades of potash feldspar are used in the manufacture of artificial teeth. For this purpose it brings the highest prices—\$6 to \$8 per barrel of 350 pounds. It is also used in the manufacture of scouring soaps and window wash. The use of feldspar of the lower grades for poultry grit, roofing, etc., seems to be on the increase, and in 1911 a small quantity was used as railroad ballast, according to Jefferson Middleton, of the U. S. Geological Survey.

## New Work at Aspen

By AN OCCASIONAL CORRESPONDENT

The prospect for a revival of mining at Aspen, Pitkin county, Colorado, rests mainly with the success of two enterprises now under way, namely, the Smuggler Leasing Co. and the Hope Mining, Milling & Leasing Co. Both are large in their conception, apparently sound in their premises, and hold out promise of great reward for those directly interested. In addition to this, it is not beyond reason to expect that their success will stimulate legitimate mining to such an extent that Aspen will again take a place as one of the principal mining centres of Colorado. It may be that the revival will not be characterized by the discovery of such rich silver deposits as marked the early days of the famous Mollie Gibson, Smuggler, Aspen, and Durant mines, but it seems certain that, if successful at

a scientist, these men of Aspen place their reliance in Mr. Spurr's work, follow its precepts, and base their hope of success upon it.

The mineral belt in the Aspen district is comparatively narrow and well defined. Its general trend is northwest and southeast. Its richest ore came from the mines on two hills, Smuggler and Aspen mountains. Before the work done on the earliest locations could be logically extended to the north and south, there was a decline in mining owing to the slump in silver following the panic of 1893, and comparatively little work has been done since that time. The continued depression has not been due to a belief that the mines were exhausted, for it was known that many favorable locations had not been worked at all, and others but slightly. Some mines were producing when they were closed, and known bodies of ore still exist in them below the water which was allowed to flood the workings. Owing to the comparatively large sums of money required to reopen the old mines and develop the new ones, combined

ASPEN AND WEST ASPEN MOUNTAIN.

all, it will result in the development of a large area of patented ground along the mineral belt which either has been idle for many years or has never been touched. It seldom happens that the second era of success in a mining district is characterized by either the rich ore or the spectacular features of the boom days; but, on the other hand, whatever it may lack in this respect, it usually supplies in the form of sound judgment, careful operation, and scientific investigation. Such has been the history of Leadville, Cripple Creek, Butte, and many other districts, and such is the prospect for Aspen.

The key-note of the two enterprises mentioned is co-operation. Both of them have been initiated and fostered by local interests; the first by capitalists who formerly made their fortunes in the silver mines of Aspen, and the second by miners, merchants, and professional men whose existence there depends on the success of the mining industry. It speaks well for the possibilities of the district when these men back their spirit of confidence by pouring cash into what had long since been regarded by outsiders as a forlorn hope. Nor is their confidence without reason; it is based on authoritative knowledge. Every man in the district is a disciple of J. E. Spurr, and is conversant with the geological work done by him and published in Monograph No. 31, U. S. Geological Survey. In pleasing contrast to the attitude sometimes taken by miners toward the work of

with the low price of silver, it has been difficult to interest outsiders in mining in Aspen. Hence, by way of showing their confidence in their own mines, and partly to protect their own interests, the citizens of Aspen have undertaken two large enterprises, one on the northern and the other on the southern end of the mineral belt.

The Smuggler Leasing Co. is the larger of the two as regards area of ground controlled and amount of money expended. The work of this company was begun several years ago when D. M. Hyman and others who had profited by former operations in Aspen, took a lease on practically all the important old mines of the district, covering Smuggler and Aspen mountains, and including Smuggler, Mollie Gibson, Della S., Bushwhacker, A. J., Durant, Compromise, and others.

The first important piece of work undertaken was the unwatering of the Free Silver shaft, which had been filled to the ninth level for fourteen years. This was accomplished, after overcoming many difficulties, and development was then commenced north of the old workings of the Smuggler and Mollie Gibson. This is the only mining work that is under the immediate direction of the leasing company; all other mining operations in this territory being conducted by sub-lessees, mainly on Aspen mountain.

The problem confronting the Smuggler Leasing Co. was the economical mining of low-grade lead-silver ore. The

new orebodies were at considerable distance from the Mollie Gibson shaft, about 3400 ft.; water had to be handled in large volume, approximating 2000 gal. per 24 hours, and lifted 1125 ft. These two items of transportation and pumping constituted the principal expense and offered the most serious obstacle to successful mining of the low-grade ore. After unwatering the Free Silver shaft, and thereby draining the workings of the Mollie Gibson and Smuggler mines, the next step was to provide adequate pumping facilities. Until evidence is adduced to the contrary, Aspen's claim to the largest and finest underground electric pumping station and machinery must be allowed. Harry Rogers, at that time foreman and now assistant superintendent for the Smuggler Leasing Co., made special effort to provide a station that would be a credit to the mine and worthy to house the fine pumping equipment that had been decided upon.

The pumping machinery which handles all the water from the mines on Smuggler mountain is placed on the twelfth level of the Free Silver shaft. The station is 91 ft. long, 21 ft. high, and 20 ft. wide. The sump is 6 ft. deep and 4 ft. wide, and extends longitudinally through the centre of the station floor. It is lined with cement. The station will accommodate five Aldrich vertical quintuplex pumps, but at present only four are in place. When the station was first cut there was room for but three of these pumps, but later it was decided to increase the capacity of the plant, and the station was extended without interfering for a minute with the operation of three pumps then in use. To accomplish this, Mr. Rogers first constructed a bulkhead of 12 by 12-in. timbers lagged on each side with 3-in. planks, between the pumps and the end of the station. This permitted drilling and blasting operations to be continued without interfering with pumping.

The Aldrich pumps are electrically driven, each pump being geared directly to two 125-hp. motors. Each pump delivers 10 gal. of water per revolution, and has a capacity of 700 gal. per minute when running at full speed. Thus the full capacity of the pumps is 2800 gal. per minute, but they are required to handle only from 1800 to 2000 gal. In the early part of July when surface water was excessive, the daily duty reached approximately 3,000,000 gal. per 24 hours, but at the last of the month it had dropped to about 2,775,000 gal. Water is lifted 1125 ft. and discharged through the old Smuggler adit. The pressure gauge at the pumps shows a weight of about 500 lb. per square inch on the pistons. It would be possible to stop these pumps for about an hour without seriously affecting mining operations, but in the event of a longer shut-down it would be necessary to use the old Jeanesville steam pumps which are held in reserve.

The pumping plant in the A. J. adit on Aspen mountain consists of a single Aldrich horizontal quintuplex pump, geared to one 90-hp. motor. This pump raises about 550 gal. per minute against a head of 620 ft., and relieves the main pumping plant of just this amount of water which otherwise would drain from Aspen to Smuggler mountain.

Owing to the low grade of the ore it was necessary to mine and treat a large tonnage, and with the old transportation equipment it was impossible to get the requisite tonnage out of the mines. Electric haulage was adopted on the thirteenth level, where all ore is collected and hauled to the Mollie Gibson shaft, where it is hoisted. Mining in the Smuggler mountain area is now being carried on in the Della S. and Bushwhacker claims, and development is being continued to the north. The Della S. is yielding low-grade mill ore containing about 10% lead and 1 to 2 oz. silver per ton, or what is locally known as '11 point' or '12 point' ore. This is concentrated by jigs and tables to about '25 point' ore containing, say, 20% lead and 5 oz. silver per ton. Fourteen 'points' is regarded as the dividing line between concentrating and smelting ore, the profit on this grade being about the same with or without concentration. The ore from the Bushwhacker is higher grade and is shipped directly to the smelter. It contains an average of 15% lead and 2 to 3 oz. silver per ton.

Hydro-electric power for the mines of Aspen is generated by the Roaring Fork Electric Light & Power Co., which has a station on Castle Creek just below the town of Aspen. Water is brought through pipe-lines from Castle, Marroon, and Hunter creeks. The principal load carried is the Smuggler pumps and hoists. This power is believed to be the cheapest hydro-electric power sold in Colorado, due to the fact that the mines require cheap power in order to operate at all, and the power company is dependent on the mines for a market.

The second important mining enterprise referred to is the Hope Mining, Milling & Leasing Co. It is a home company and reflects a spirit of coöperation and confidence that commends itself to any mining company that is temporarily depressed. The company was organized to secure a lease and bond on the most favorable properties in the district. It was capitalized for \$50,000, divided into shares of \$1 each. Provision was made for subscriptions as small as \$12, payable \$1 each month, and no work was to be undertaken until the sum of \$12,500 had been subscribed, payable within a year. No salaries are paid to any officers and no expense is incurred for any other than necessary and legitimate mining operations. In some instances labor and supplies have been given, wholly or in part, for stock. Monthly reports of receipts and expenditures are published in the local newspapers, and everyone is advised regarding the progress of the work. Ten-year leases with bonds have been secured on the Little Annie group of eight claims, the Little Annie adit and concentrating mill, the Famous adit, Slide group of five claims, the Atlanta, One-Half, and Calaveras group of five claims. All of this territory lies on the southern end of the mineral belt. The Little Annie had some reputation years ago as a good producer of silver-lead ore, but was allowed to lapse into unproductiveness after 1893. It was worked by shaft and adit, but no work of importance was done below the adit-level.

The important and promising feature of the Hope company lies in the extension of the Famous adit, which will be driven under the Little Annie to a depth of 1500 ft. below the old level. Several important faults will be cut in its course, and the prospects of finding ore is good. The other groups mentioned can be developed through the Famous adit, and it is likely that the drainage of the Little Annie adit will be accomplished as the lower level is advanced. This will make it possible to mine immediately in the Little Annie orebodies. About 150 Aspen merchants, miners, and professional men have interested themselves in this venture in amounts ranging from \$12 to \$500. The developments of the next year will reveal what can be done, and it is expected that the results will warrant continued operation. At present the company has a steam-driven compressor, but the position of the adit is such that water-power can be easily developed on Castle Creek. Mining operations are under the direction of Henry J. Turley, and the business of the company is in the hands of a board of directors consisting of Charles O'Kane, J. W. Hetherly, Harold W. Clark, John B. Stitzer, Alphonse Peterson, and H. J. Turley.

In addition to these resources in metallic minerals, Aspen has non-metallic mineral deposits of potential value. Farther up Roaring Fork above the town are the granite quarries of the Roaring Fork Granite Co. Five hundred acres of granite are ready for development, and ample water power is at hand for all purposes. On Marroon creek, west of Aspen, are deposits of marble said to be of good quality, and offering opportunity for development.

QUARTZ PRODUCTION in 1911, according to the U. S. Geological Survey, was 86,823 short tons, valued at \$151,122, an increase in quantity of 23,246 tons and in value of \$42,635 over 1910. The increase in quantity was entirely in the crude quartz, the ground material decreasing in both quantity and value. The production of the quartz in 1911 was the largest during the past five years except that of 1909, when the output was 121,459 short tons, valued at \$131,334.

# The Miners' Side of the East Tintic Decision

By F. J. H. MERRILL

Few decisions of the Department of the Interior interpreting the mining laws have excited as much interest and aroused as strong a protest as that in the matter of the East Tintic Consolidated location. The Salt Lake Stock & Mining Exchange and the Salt Lake Commercial Club have passed resolutions of protest, of similar import, the first of which has been communicated to the Secretary of the Interior, and the latter has replied at some length, stating in detail the position of the Department. The questions raised are of very general interest, and the communications, which have come into my hands through the Los Angeles Chamber of Mines & Oil, are here given, with some comments from the miner's point of view.

## RESOLUTION ADOPTED BY THE SALT LAKE STOCK MINING EXCHANGE, MAY 8, 1912

*Whereas*, recent decisions of the Department of the Interior and the Land Office have tended to place new construction upon the mining statutes, making it in some cases difficult and in other cases impossible to secure patents to claims covering valuable mining property located in demonstrated mineral districts; and,

*Whereas*, in many cases where it is desired to locate only a small fraction of ground, and in other cases where the depth of the mineral deposits is so great that the cost of making actual discovery on each and every claim is prohibitive and tends to a waste of money in useless work that, after patent, serves no purpose in developing the claim; and,

*Whereas*, the Department of the Interior, by these decisions revolutionary in their effect, has announced that it is no longer sufficient for the locator of a lode-mining claim before securing patent to discover mineral-bearing rock in place, but that such locator must prove that ore of commercial value exists within the limits of each and every claim before the Department will pass such claims to patent; and,

*Whereas*, the mining industry of the West is being retarded and hampered in some cases by the deficiencies in existing laws, and in other cases by the new and strained construction of the law; now, therefore, be it

*Resolved*, by the Salt Lake Stock & Mining Exchange, that it would be greatly to the advantage and benefit of the mining industry of the Western states if legislation along the following lines were enacted: That, to correct the recent ruling of the Department of the Interior, requiring that the existence of mineral value be discovered on each and every claim as a prerequisite to patent, Congress should enact legislation so as to make it plain that in all cases where mining claims are situated in a recognized mineral district and the land embraced therein has no value for its timber, power sites, water sources, or for agricultural purposes, but is valuable only for its mineral resources, it shall be sufficient in the case of lode claims to discover mineral-bearing rock in place or to geologically demonstrate the same without actual discovery of the presence of mineral, and in the case of placer claims, in like circumstances, to either discover mineral or to geologically demonstrate without actual discovery the existence of mineral within the limits of the claim, and that any discovery or indications of mineral upon which a reasonably prudent man would be justified in expending his time and money in the development of such claims in the hope of ultimate success, should be sufficient to satisfy the Land Department.

And be it further

*Resolved*, that a copy of this resolution, together with such endorsements as may be secured, be forwarded to the Utah Congressional delegation, with the request that they use their influence and put forth their efforts to secure such legislation.

This resolution, which is similar to the one passed by the Commercial Club of Salt Lake City, was communicated to the Department of the Interior by Joseph Howell, Representative at large for Utah, and the following letter was received by him in reply:

Hon. Joseph Howell,

House of Representatives.

Dear Sir—Referring to a copy of resolution adopted by

the Salt Lake Stock & Mining Exchange relative to proposed amendments of the statutes regulating the disposition of the mineral lands of the United States, personally presented by you; the third resolution reads as follows:

*Whereas*, the Department of the Interior by these decisions, revolutionary in their effect, has announced that it is no longer sufficient for the locator of a lode-mining claim before securing patent to discover mineral-bearing rock in place, but that such locator must prove that ore of commercial value exists within the limits of each and every claim before the Department will pass such claims to patent;

This, it is believed, misconstrues the recent decision of the Department in the case of the East Tintic Consolidated Mining Claim (40 L. D., 271), decided September 11, 1911.

Section 2318, Revised Statutes, reserves from sale, except as otherwise expressly directed by law, all "lands valuable for mineral." Section 2319, Revised Statutes, declares that "all valuable mineral deposits" are free and open to exploration and purchase. Section 2320 provides:

Mining claims upon veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits, heretofore located, shall be governed as to length along the vein or lode by the customs, regulations, and laws in force at the date of their location. A mining claim located after the tenth day of May, eighteen hundred and seventy-two, whether located by one or more persons, may equal, but shall not exceed, one thousand five hundred feet in length along the vein or lode; but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located.

Under the above provisions it is clear that there must be a discovery of a vein or lode containing a valuable mineral deposit.

In East Tintic Consolidated Mining Claim, the Department held, at page 273:

By the term 'vein or lode', as used in the foregoing, the Department is not to be understood as having in mind merely a typical fissure or contact vein, but, rather, any fairly well defined zone or belt of mineral-bearing rock in place.

It is evident from the record before the Department that the deposits alleged to have been exposed on these claims are regarded by the applicant as possessing practically no economic value, but that on the other hand title to the claims is sought essentially on account of their possible value for certain unexposed deposits supposed to exist at considerable depth beneath the surface, and having no connection, so far as shown, with any deposits appearing on the surface. The exposure, however, of substantially worthless deposits on the surface of a claim; the finding of mere surface indications of mineral within its limits; the discovery of valuable mineral deposits outside the claim; or deductions from established geological facts relating to it; one or all of which matters may reasonably give rise to a hope or belief, however strong it may be, that a valuable mineral deposit exists within the claim, will neither suffice as a discovery thereon, nor be entitled to be accepted as the equivalent thereof. To constitute a valid discovery upon a claim for which patent is sought there must be actually and physically exposed within the limits thereof a vein or lode of mineral-bearing rock in place, possessing in and of itself a present or prospective value for mining purposes; and before patent can be properly issued or entry allowed thereof, that fact must be shown in the manner above stated.

This is not a holding that there must be a discovery of ore of commercial value. The conditions present were, as found by the Department, that upon the surface there were slight indications of mineral such as would not warrant a reasonably prudent man in spending his time and money in an effort to extract mineral, but the geological conditions were such as to induce the belief that at a greater depth there was a valuable deposit of mineral. Such a belief, it was held, could not be accepted as a discovery. The decision was not revolutionary, but was an evolution from the prior decisions and regulations of the Department. It is proper to say that a motion for rehearing in this case has been filed, and that there are other cases also pending involving like questions.

In the case of the Silver Jennie Lode (7 L. D., 6) it appeared that there was a vein or lode upon adjoining ground which the applicant for patent believed to extend

into the Silver Jennie claim, but it had not been actually disclosed and could not be disclosed without a great deal of additional development, entailing a large expenditure. The Department, however, was of the opinion that this was insufficient as evidence of discovery, and held:

Evidence as to the discovery of the alleged vein or lode should be furnished showing the place where, and when the discovery was made, the general direction of the lode or vein, and all the material facts in relation thereto; and such evidence should be clear and positive, and based on actual knowledge and the witnesses' means of information be clearly set forth.

The case of *Castle v. Womble* (19 L. D., 455) laid down a rule which has since been followed by the Department, and has been quoted with approval by the courts. Its syllabus reads:

A mineral discovery, sufficient to warrant the location of a mining claim, and the evidence shows that a person of ordinary prudence would be justified in the further expenditure of his labor and means, with a reasonable prospect of success in developing a valuable mine.

The Department has consistently held that a mere belief is not equivalent to a discovery; also the fact that land is returned as mineral does not obviate the necessity of a discovery. (*Reims v. Murray*, 22 L. D., 409.)

In *Henderson et al. v. Fulton* (35 L. D., 652) the Department considered a definition of the word vein or lode. At page 656 it quoted Justice Field's language in *Eureka Consolidated Mining Co. v. Richmond Mining Co.* (4 Sawyer, 302):

The miners made the definition first. As used by the miners, before being defined by any authority, the term lode simply meant that formation by which the miner could be led or guided; it is an alteration of the word lead; and whatever the miner could follow, expecting to find ore, was his lode.

The difficulty in the East Tintic case was, as found by the Department, that the formation disclosed was not such as to lead the miner to find, or expect to find, any deposit of ore therein, but that the only real indication of a valuable mineral deposit being found in the land was his belief founded upon the geologic conditions and mining development of the district.

Paragraph 41 of the mining regulations adopted March 29, 1909:

The vein or lode must be fully described, the description to include as to the kind and character of mineral, the content thereof, whether ore has been extracted and of what amount and value, and such other facts as will support the applicant's allegation that the claim contains a valuable mineral deposit.

Prior to the adoption and enforcement of this regulation, the evidence of the existence of a vein or lode was, in the greatest percentage of cases, the *ex parte* showing of the applicant for a patent, which frequently was perfunctory in character. The acceptance of such showings by the Land Office undoubtedly led to the issuance of patents for mining claims upon which no discovery of a vein or lode had in fact been made. It is rather the enforcement of the existing law requiring the discovery of a vein or lode, than any change in the Department's regulations thereof which has caused the difficulties which give rise to the adoption of the resolutions by the mining exchange.

The Department is of the opinion that legislation, supplemental to the present mining statutes, is advisable. There are areas of public lands in which mineral deposits are believed to be contained, but which, if there, lie at great depth, and upon which discoveries cannot be made without large expenditures, while under the existing law a valid location cannot be made until a discovery has been accomplished and the prospector is therefore not fully protected. The Department believes that legislation should be enacted authorizing it to grant a permit giving an individual, or individuals, the exclusive right to prospect a certain tract of public land for the mineral it is thought to contain, for a limited period of time. Such legislation should contain provisions requiring a certain amount of annual development work as an earnest of good faith, restricting the area and the number of claims that could be

held under such a permit, and requiring within a limited period of time the purchase or lease from the United States of the mineral deposits, retaining the fee of the land in the United States, which could then dispose of the surface as conditions might warrant. This legislation would also well supplement Senate Bill No. 6194, now pending before the Senate, which in brief, as to future locations, abolishes extralateral rights, requires notices of location to be also filed for record with the Register and Receiver of the proper Land Office, and also requires final entry and payment to be made in seven years from the date of the location.

Very respectfully,

(Signed) SAMUEL C. ADAMS.

First Assistant Secretary.

In general consideration of this subject it may be said that, as a rule, the prospector and miner do not so much object to strict interpretation and enforcement of existing laws as to radical and abrupt changes in their interpretation. Those having a right to locate mining claims have also the right to ask that changes in the laws and rules governing locations and patents shall not be made without due notice, for in law-making bodies, regard is usually paid to business necessities, and due notice is given of contemplated changes in legislation. While there is a technical distinction between the Federal statutes on mineral lands and the decisions of the Department of the Interior interpreting these statutes, these decisions are virtually law for those transacting business under them.

The position taken in the foregoing letter appears chiefly to be that public welfare requires a more literal interpretation of existing statutes than has hitherto been customary. On general principles this might be desirable, but, in this particular instance, it is difficult to see how a stricter enforcement of the law will benefit the nation.

The view expressed would be more appropriate if locations on outcrops of metallic ore, necessarily involved the transfer of valuable mineral land from the Government to some individual or group of individuals. What proportion of mineral locations pass to patent is not known, but my observation leads to the opinion that not more than one prospect in one thousand proves of value when developed. Surely this matter should be considered in framing the mining laws and in their enforcement. If land does not clearly show mineral of value, and is not valuable for agricultural or other purposes, how does it benefit the nation to withhold it from location, or even from patent? Is it a public duty to prevent the miner from paying his money to the nation for land which is valueless? Seemingly the nation would be more benefited by accepting cash for land which otherwise would not be sold.

In the revision of the mining laws, now contemplated, there have been in view two principal points which have molded opinion regarding needed changes: (A) revision in the light of more complete knowledge of facts and conditions in mining; (B) protecting or conservation of the public domain in the interest of the people.

A fact often overlooked in discussing this subject is that the mining industry was founded on mineral deposits exposed at the earth's surface. The processes of ore deposition, however, are separate and distinct from those of erosion, and the fact that an ore deposit exists beneath a given area does not necessarily involve the progress of erosion to the point of exposing any part of that deposit or in any way revealing its existence. As time passes and the mining industry advances, the discovery of ore deposits becomes a more complex and costly matter than it formerly was. For, in the better known areas, most of the valuable orebodies which were well exposed and easy to find, were found some time ago. It is obvious that, in the near future, we shall come more and more frequently to seek for orebodies of which there is no suggestion at the surface. Therefore, any adequate system of mining laws must provide for and protect such exploration work as may be necessary to determine the presence or absence of mineral deposits without surface outcrop.

## Prospecting for Bauxite-Aluminum Ore

By W. C. PHALEN

*\*Introduction.*—Though experiments have been made and are still in progress on the extraction of metallic aluminum from clay or silicates containing it in considerable amount, it still remains a fact that the mineral bauxite is the only commercial source of metallic aluminum. When it is considered that the price of the metal has varied between 24c. per lb. as a maximum and 18½c. as a minimum during the two years 1910 and 1911, prospecting for the raw material—the source of the metal—becomes a matter

of some importance. In such a case, recourse must be had to quantitative analysis in order to determine the true nature of the substance. In color, bauxite varies from white or gray through the shades of yellow and brown to red. It is not a heavy mineral, its specific gravity being 2.5. In composition it is a hydrated aluminum oxide with the symbol  $\text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , containing alumina ( $\text{Al}_2\text{O}_3$ ) 73.9% and water ( $\text{H}_2\text{O}$ ) 26.1%. The pure mineral is of rare occurrence, the commercial grades carrying varying amounts

PEBBLES FROM 'PEBBLE ORE.'  
TYPICAL OOLITE ORE.

PISOLITIC ORE VERGING TO PEBBLE ORE.  
TYPICAL OOLITE ORE.

of some importance, particularly when the additional facts are considered: (1) that the metal is with us to stay; (2) that it is finding a constantly enlarging field of usefulness, and (3) that more than 23,000 short tons was consumed in the United States during 1911.

*Properties.*—Bauxite is a mineral which can readily be recognized in the field, even by the inexperienced. Its most striking and common characteristic is its oölitic or pisolitic structure. The oölitic and pisolitic grains are small approximately round bodies varying from the size of a pea up to an inch in diameter. In some places the ore has the appearance of gravel, the oölitic separating readily from the matrix, which resembles clay. In some occurrences the matrix and oölitic are firmly cemented, forming compact ore. Rather rarely the mineral resembles ordinary grayish or yellow clay so closely that its nature may be entirely unsuspected, especially when such an oc-

currence is somewhat isolated. In such a case, recourse must be had to quantitative analysis in order to determine the true nature of the substance. In color, bauxite varies from white or gray through the shades of yellow and brown to red. It is not a heavy mineral, its specific gravity being 2.5. In composition it is a hydrated aluminum oxide with the symbol  $\text{Al}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ , containing alumina ( $\text{Al}_2\text{O}_3$ ) 73.9% and water ( $\text{H}_2\text{O}$ ) 26.1%. The pure mineral is of rare occurrence, the commercial grades carrying varying amounts

*Tests.*—A few simple characteristics by which the mineral may be determined in the field are: (1) It is infusible or difficultly fusible; (2) it is insoluble in or but slightly acted upon by hydrochloric acid; (3) it is soft and can be readily scratched with a knife; (4) when treated with cobalt nitrate it assumes a blue color before the blow-pipe; and (5) when heated in a closed tube, water is given off. Other minerals like kaolinite and others of the kaolinite group, together with gibbsite, give the simple reactions indicated above. The peculiar concretionary structure of bauxite then serves as a distinguishing characteristic and when absent, as already mentioned, a quantitative analysis should be made.

\*Published with the permission of the Director of the U. S. Geological Survey.

*Occurrences.*—The known occurrences of bauxite are

really the only guide in searching for new sources of the mineral. As, however, it is known to occur under widely different conditions, and as it may be expected to occur under still other and at present unsuspected conditions, the prospector must be on the alert and not rely too implicitly on the assumption that the mineral will be found only under conditions already known. As a concrete example of this statement may be mentioned the last important find of bauxite, namely, that in central Georgia, where the mineral occurs in an entirely different manner from what it does in the northwestern part of the same state, and where in turn the geological occurrence of the mineral is quite different from that in Arkansas. In the same type of country, geologically speaking, it is reasonable to assume a uniformity of conditions of occurrence.

*Foreign Sources.*—The best known foreign occurrences of bauxite are in the departments of Hérault, Bouches-du-Rhône, and Var, in southeastern France near the Italian border. The first valuable beds of ore were discovered in the vicinity of Les Baux in the department of Bouches-du-Rhône, northwest of Marseilles—which accounts for the name of the mineral bauxite—pronounced in French as if it were 'bo'zit', but more commonly known here as 'box'ite.' The bauxite of Baux occurs in highly tilted beds associated with limestones, sandstones, clays, or in pockets and cavities in limestone. Other deposits in the south of France either rest upon or are associated with limestone. Such deposits are thought to have resulted from hot spring or geyser action. Other French deposits, for example those of Puy de Dome, rest on gneiss and are partly covered by basalt and have no connection whatever with limestone. Certain of the German and Irish occurrences have been shown to have been derived from basalt.

In the United States bauxite occurs in commercial quantity and is worked in Arkansas, Georgia, Alabama, and Tennessee. An important deposit is known in Botetourt county, Virginia.

*Arkansas Deposits.*—In Arkansas the beds of bauxite are situated in Saline and Pulaski counties. The great bulk of the mineral produced in this State in 1911 was mined near the town of Bauxite, on the Chicago, Rock Island & Pacific railway, about five miles east of Benton, the county seat of Saline county, and 22 miles southwest of Little Rock, the state capital. In Arkansas the bauxite beds rest directly on kaolinized syenite and occur in undulating layers corresponding to the surface of the syenite. The ore covers many of the hills completely, occurring on their sides as well as their tops. It tapers out rather abruptly approaching the ravines and is absent in many of them. In thickness it varies from a knife edge to a possible maximum of 30 ft. The Arkansas ore occurs in at least three forms—the granitic, pistolitic, and the compact or clay-like form. Where the bed has been so opened as to show the underlying syenite, its lower part next to the syenite consists of the granitic ore—that is, the ore is pseudomorphous after syenite. The second and the third forms occurring in this state have already been mentioned.

Various theories have been propounded as to the origin of the Arkansas bauxite. All seem to agree that it is genetically related to the syenite. Though important deposits of bauxite in connection with igneous rocks are not known in other parts of the United States, occurrences of rock composition similar to the Arkansas syenite are not rare.<sup>1</sup>

*Georgia-Alabama Deposits.*—The deposits of bauxite in northwest Georgia and northeast Alabama are comprised in one bauxite field in which the geologic and structural relations of the ore deposits apparently are the same. The district as a whole extends along the Coosa valley from the vicinity of Summersville or Adairsville, Georgia, to Jacksonville, Alabama. It lies chiefly in Bartow and Floyd counties, Georgia, and Cherokee county, Alabama. Not

the whole of the district, or even a large part of it, has been prospected, and it is more than likely that new deposits of bauxite may be discovered from time to time.

Most of the bauxite mines in this field and near Chattanooga, Tennessee, consist simply of rounded or ellipsoidal deposits a few hundred feet in diameter at the surface and tapering roughly to a point as they descend. None of them are more than a few hundred feet deep at the most. The deposits in the Georgia and Alabama field occur in the residual clay derived from the weathering of dolomite or limestone. The calcareous rocks overlie a great mass of shale, and numerous faults intersect the rocks. According to C. W. Hayes,<sup>2</sup> who has studied the deposits, it is believed that surface waters reached the shale and, oxidizing their pyrite content, set free sulphuric acid. This, reacting with the alumina of the shales, formed sulphate of aluminum. Ascending currents carried the sulphates in solution upward toward the surface, where in contact with the limestone during their upward passage, they were decomposed and aluminum hydrate formed. Whatever the origin of the deposits may be, the almost constant association of limonite or iron ore and kaolin is worthy of mention and may furnish an important clue in finding future deposits.

*Tennessee Deposits.*—The deposits in Tennessee are situated on the southeastern slope of Missionary ridge near Chattanooga. They are of the same nature as those farther south in the Georgia-Alabama field just described, and indeed they may be considered as a northern continuation of the deposits of the older and better known field. The ore is found in the Knox dolomite near a fault line along which the Knox has been overthrust from the southeast upon the Chickamauga and Clinton formations lying to the northwest. These geological and structural conditions are essentially identical with those farther south in Georgia and Alabama. The extension of such deposits to an area far north of that already known, emphasizes the value of a close study of the structure in the Cambrian and the Ordovician rocks in the southern Appalachian region in all future attempts to extend the bauxite-bearing areas.

*Central Georgia.*—Bauxite occurs in Wilkinson county, central Georgia. The deposits are in no way connected with those in the northwestern part of the state, either geographically or geologically. They are 150 miles away near the northern margin of the coastal plain, the nearest city being Macon, 30 miles to the west. The bauxite apparently occurs near the contact between the Lower Cretaceous and the Claiborne group (Eocene), which are chiefly made up of unconsolidated sands and clays lying flat and having no pronounced structural features. The bauxite occurs in the form of beds either resting directly upon the Cretaceous clays or disseminated as nodules through them. Beds 10 ft. in thickness have been observed. The ore is generally either pisolitic or concretionary, but is all amorphous. In color it varies from almost white or cream to a bright red. It is generally hard, but clay-like varieties have been discovered. The tentative opinion has been offered that the bauxite is an alteration product of a bed of white clay or kaolin and has resulted from it by desilication.

The points at which the bauxite is most likely to occur may be approximately determined by finding the white clay beds, locally known as the 'chalk' beds, as the bauxite has been found contiguous to the clay near its contact with the overlying red sands and impure clays. The geologic conditions prevailing in Wilkinson county are also found in Twiggs, Washington, Glascock, McDuffy, and Richmond counties, and bauxite may be found in any or all of these.

*Uses of Bauxite.*—The chief uses of bauxite are: (1) as raw material in the production of metallic aluminum; (2) in the manufacture of aluminum salts; (3) in the manufacture of bauxite bricks, and (4) in the manufacture

<sup>1</sup>U. S. Geol. Survey, Prof. Paper No. 14, 1903, pp. 198-199.

<sup>2</sup>Twenty-first Ann. Rept. U. S. Geol. Survey, Pt. 3, 1901, p. 461.

of alundum (fused alumina) for use as an abrasive. The use of bauxite in the manufacture of calcium aluminate to give a quick set to plaster composition should be added, as well as the extended use which alundum is finding in the refractory industries.

The use of bauxite in the production of metallic aluminum is by far the most important of those enumerated above. A large part of the entire output of Arkansas is used in the metallic aluminum industry, and the figures of production from that state have shown phenomenal growth during recent years. A large part of the French product is also used in the manufacture of metallic aluminum. Only the purer bauxite is used in the manufacture of chemicals, such as alum, aluminum sulphate, and aluminum salts in general. Freedom from oxide of iron is essential in the material to be used in chemical manufactures. Bauxite is used on a large scale in the manufacture of the artificial abrasive alundum at Niagara Falls. This abrasive is made in an electric furnace by fusing calcined bauxite. It is high in crystalline oxide, and virtually amounts to a form of artificial corundum. Its quality is under complete control and hence it can be duplicated with ease in the various abrasive products, a factor of great importance in the success of the abrasive industry.

*Other Possible Sources of Alumina.*—In a report I prepared a few years ago the statement was made, which still holds good, that the expiration of the aluminum process patents, and the great increase in output of metallic aluminum, have given rise to many scientific researches and commercial inquiries regarding new methods of producing metallic aluminum. These inquiries are appropriate in view of the fact that bauxite is found in comparatively few places, must be transported long distances, and contains so much silica as to require costly chemical operations to purify it for the manufacture of metallic aluminum. Aluminum silicates, on the other hand, are found almost everywhere, and the separation of the silica from them may at some future time not cost more than to counterbalance the scarcity, inaccessibility, and impurities of the bauxite deposits.

Attention has recently been called to the mineral alunite, having the formula  $K_2O \cdot 3Al_2O_3 \cdot 4SO_3 \cdot 6H_2O$ , as a source of alumina, and hence of metallic aluminum. Experiments performed in the laboratory of the United States Geological Survey have showed that on igniting powdered alunite all of the water and three-fourths of the sulphuric acid are volatilized. On leaching the residue with water the potassium sulphate is dissolved, leaving the insoluble aluminum oxide behind. The average amount of potassium sulphate leached from the ignited mineral powder is 17.9% of the original material used. As the coarsely crystallized alunite was found to contain 19.4% of potassium sulphate, 92% of the total potash present was obtained by simple ignition and subsequent leaching. According to the laboratory experiments which were carried out by W. T. Schaller, 32.7% of the ignited alunite consists of available potassium sulphate which can be extracted by simple water leaching and evaporation. The remaining 67.3% consists of nearly pure aluminum oxide. The alunite used in the experiments just alluded to, came from near Marysville, Utah, where is situated what seems to be the largest known deposit in the United States. Beside the Utah deposit, the mineral alunite is known to occur in the Rosita hills, in the Rico mountains, at Silverton and Cripple Creek, Colorado. Other important occurrences in the Western states are at Goldfield, Nevada, Tres Cerritos, California, in the Clifton-Morenci district, Arizona, and in Beaver county, Utah.

## Another Universe

Spiral nebulae are discussed entertainingly by Edward Arthur Fath in the September *Century*. One result of his work has been the discovery of 14 absorption lines in the spectrum of the Andromeda nebula which corresponded, line for line, with absorption lines in the solar spectrum.

A photograph of the spectrum of the sun taken with the same instrument looks precisely like that of this particular nebula. This implies that the Andromeda nebula has the physical characteristics of the sun. The nebula is four times the apparent diameter of the sun. Its distance is not known, but a conservative estimate would place it among the nearer stars. If this assumption be correct, it places the nebula at least ten million times as far away as the sun is from the earth. Consequently its real dimensions are at least forty million times those of the sun. Since the diameter of the latter is 866,000 miles this gives nearly 35,000,000,000,000 miles as the diameter of the nebula. This great body gives a solar spectrum, and the simplest assumption seems to be that it is a vast assemblage of suns so far from us that no telescope has been able to show the suns separately. If this be true, it is not among the stars, for these can be seen separately in the telescopes, but beyond the stars. This would make it another universe.

## Goldfield Consolidated Report

By J. F. THORN

During the month of July 1912 the total production of the Goldfield Consolidated company was 31,907 tons, containing \$474,955.84, or an average of \$14.89 per ton, of which 29,000 tons was milled with an average extraction of 91.05%, and 2907 tons was shipped of an average value of \$16.42 per ton, the net recovery from all ore being \$13.69 per ton. The total net realization was \$238,278.70 or \$7.47 per ton. Development during the month amounted to 2923 ft. The total cost of mining, development, transportation, milling, office, and general expense was \$6.41 per ton, distributed as follows:

Mining (including stoping and developing).....	\$3.18
Transportation .....	0.08
Milling .....	1.97
Marketing .....	0.05
General expenses .....	0.40
Bullion tax .....	0.05
Marketing ore shipped .....	0.66
Construction .....	0.07

Total cost of operation.....	\$6.46
Miscellaneous earnings .....	0.05

Net cost per ton.....\$6.41

In the Combination mine the 402-G stope, 300 ft. north of the shaft between the fifth and sixth levels, produced 399 tons of \$30 ore, this being the deepest point in the mine at which ore has been found. A new stope on the second level, 80 ft. east of the 136 stope, produced 275 tons of average \$17 ore.

In the Mohawk the 3-J sill, north of the 3-E stope in the old Sheets-Ish workings, produced 279 tons of average \$28 ore. The 170-J stope on the 250-ft. level or the downward extension of the old Sheets-Ish stope produced 69 tons of \$58 ore. The 202 stope, which is being carried through the old Frances-Mohawk workings, produced 68 tons of \$40 ore. A new raise at the south end of the 348 stope, between the 450 and 350-ft. levels, has entered a body of ore assaying \$40 per ton. An important development was made on the intermediate level between the 450 and 600-ft. levels, about 700 ft. north of the shaft. The 426-X cut penetrated a body of ore, and the 490-I sill, which is being cut in the ore, produced 755 tons of \$40.80 ore.

In the Clermont the 571 drift on the downward extension of the 510 orebody, between the 750 and 900-ft. levels, produced 55 tons of \$40 ore. In the Grizzly Bear 250 tons of ore averaging \$30 per ton was shipped from development on the 1300-ft. level. Work on this level has advanced slowly on account of being carried on in conjunction with sinking the shaft. The 1400-ft. level of the shaft will be reached during the coming month, and lateral work from both levels can be carried on more rapidly.

## Miners' Phthisis in Western Australia

Four important commissions have made reports in Western Australia, on questions connected with the health of miners. These are: (1) 'Ventilation and Sanitation of Mines,' by A. Montgomery, in 1905; (2) 'Pulmonary Diseases Among Miners,' by J. H. L. Cumpston, in 1910; (3) 'Composition of Gases Caused by Blasting in Mines,' by E. A. Mann, in 1911; and (4) the recently issued 'Report of the Royal Commission on Miners' Lung Diseases.' The investigations by Dr. Cumpston were primarily to see if phthisis, or fibrosis, as he better calls such lung troubles,

considered this chart especially valuable, and reproduced it on a large scale, with additions, the result of investigation. We reproduce the amended chart herewith. The report also gives details of underground work in many mines, their temperature, amount of air used, analysis of ores, carbon dioxide in mines after blasting, and notes from dry-crushing plants. Numerous letters and tables are also given, besides 'Notes and Measures Taken for the Prevention of Dust in Johannesburg,' by R. N. Kotze, the acting mining engineer for the Transvaal Government.

Appendix 34 of the report is of value, as it is on the 'Nature and Constitution of the Dust in the Kalgoorlie Mines,' by C. O. G. Larcombe, of the local School of Mines. This was a rather difficult investigation, and needed great care and study. Mr. Larcombe personally collected dust

from various Kalgoorlie mines, on both sides of slides by means of a coating of Canada balsam. Miners also wore respirators for certain times under varying conditions, and the dust from them was collected, centrifuged, dried, weighed, and microscopically examined, with the following results:

1. It was found that the physical character of the dust has an important bearing on the subject. The Kalgoorlie dust contains under 50% of free quartz. Any dust made up largely of quartz, which breaks with a shell-like fracture, and, when in a fine state of division, tends to become splintery, must be dangerous. The dust from the mines of the Golden Mile is made up of a number of minerals, whose hardness range from 2 to 7, and in specific gravity from 2.65 to 5.1.

2. An analysis of collected dust shows it to contain silica, carbonates of lime and magnesia, sericite, pyrite, and apatite. The constituents, besides quartz and pyrite, are relatively soft. Excepting the carbonates and apatite, the remainder are insoluble in hydrochloric acid.

3. Three sizes of dust were collected and examined. The impalpable dust, consisting of rounded and granular particles from 1/2500 in. long and wide, and same thickness, to particles 1/8000 and 1/10,000 of an inch. The medium-grained dust ranged from 1/500 to 1/2500 in. long by 1/1500 in. thick. The coarse dust is as big as 1/33 in. wide 1/16 in. long, and 1/100 in. thick. When boring dry holes underground, in a drift 7 by 5 ft., 3,000,000 particles of dust per square inch collected near the face, but when boring wet, only 194,500 particles were found at the same place.

Some interesting diagrams and micro-photos are reproduced, showing the relative

amounts of dust collected under these conditions. Mr. Larcombe concludes by saying that the dust in the mine atmosphere at Kalgoorlie compares most favorably with the dust from any other centres, and is less dangerous than that at Bendigo or on the Rand. The whole report is a valuable addition to the existing literature on the subject.

TWO ADDITIONAL RULES have been lately added to the Mines Regulation Act of Western Australia: (1) When so directed by an inspector, the manager shall have gates securely fixed upon cages, during such time as they are employed at the change of shifts for lowering and raising men; and (2), where, in the opinion of the inspector, the dust from tailing dumps, or any other heaps of waste rock or mill residue in a mine is a nuisance to persons employed on them, or in their vicinity, and detrimental to their health, he shall give notice in writing to that effect; and the manager shall thereupon provide, and cause to be constantly used, such spraying appliances as will effectively lay the dust.

LAMB'S CURVES OF DISCOMFORT REVISED.

was present among miners. As he proved it to be, the business of the last commission was to inquire further, and make suggestions for legislation on the subject. Mr. Mann's excellent work was to prove the quality of explosives used, and their general effect on mine air.

Abstracts of the proceedings, and summings up of the last commission, have been commented upon already in the *Mining and Scientific Press*, yet a few points in the last report may still be of interest. In the commission's report there are 269 sections or summaries on the various questions at issue. At the different mining centres visited in Western Australia, 7195 questions were asked and answers given by managers, miners, doctors, insurance people, and others. There are in addition appendices to the report on meteorology and on state of air in many mines; the latter under the heads of locality, carbon dioxide present, dry bulb temperatures, percentage of saturation, and degrees of discomfort, as read from Lamb's chart in his paper, 'Curves of Comfort,' published in the *Mining and Scientific Press*, August 27, 1910. The commission con-

# Electric Smelting of Iron Ore

By E. F. BURCHARD

\*The direct reduction of iron ore by means of an electric current is a problem that has engaged the attention of certain electro-metallurgists for the past ten or twelve years. According to J. B. C. Kershaw, in the *Iron Trade Review* for January 4, 1912, the first experiments were made by Captain Stassano, an Italian, at Rome, in 1899-1901, and later at Darfo, in northern Italy, where cheaper electric power was available. Stassano's furnace was of a revolving arc type with 3-phase current and water-cooled electrodes, and this type of furnace is still employed by Stassano for refining steel by electricity. Stassano's experiments proved that good iron could be produced in this way direct from the ore. The iron ore was first ground, and after mixing with lime and coke, was briquetted before being charged into the furnace—an expensive preliminary treatment. The power required in this process was estimated to be 2866 kilowatt-hours per ton, costing \$18.60, and when the cost of materials and labor were added to the already exorbitant power cost the impracticability of the process, from a financial standpoint, was readily apparent. Keller, a French electro-metallurgist, carried on extended experiments in his own electric furnace at Kerrouze and Livet, France, from 1901 to 1905. In the Keller process, the ore, coke, and limestone were coarsely crushed and mixed before charging into the furnace, which had two shafts, connected below by a canal which collected the molten iron. A reduction in power and costs was accomplished by the Keller process, which is estimated to have required 2292 kilowatt-hours of power for a ton of 2000 lb., at a cost of \$12.05.

In America, Heroult, another French electro-metallurgist, made a trial of a shaft type of furnace at Saut Ste. Marie, Canada, in 1905-6, under the auspices of the Canadian Government. This early Heroult furnace was of the square-shaft type, and was much simpler than those of Stassano and Keller, and by its use it was estimated that the consumption of power for a large plant would approximate 1490 kilowatt-hours per ton of pig iron, at a cost of only \$2.43. The estimated cost of native magnetite iron ore was \$1.50 per ton; of charcoal, which was used instead of coke, \$6 per ton of iron; and of labor about 76c.; a total cost of \$10.69 for labor, ore, and power supply requisite for a ton of pig iron. These costs were not, however, attained by actual practice, and the project of establishing an electric iron smelting industry on the Canadian side of the Great Lakes was temporarily, at least, abandoned. In 1906 to 1910 three Swedish engineers, Gronwall, Lindblad, and Stalhane, carried on extensive experimental work on the problem, building with the assistance of a number of iron manufacturers in Sweden two electric furnaces at Domnarfvet, and a third at Trollhättan. The design of the Gronwall electric furnace is similar to that of a miniature blast-furnace with the tuyeres replaced by electrodes. E. Haanel, director of the mines branch of the Canada Department of Mines, made a series of test trials with the Gronwall furnace at Domnarfvet in 1908, using Grangesberg magnetite. Based on the yield under favorable conditions, it has been estimated that the power consumption might be reduced to less than 2000 kilowatt-hours per ton of pig iron, and that for a furnace producing 8000 to 10,000 tons of pig iron per annum, the cost of charcoal, power, labor, electrodes, and repairs should total about \$8.56 per ton of iron, to which must be added for cost of ore, interest on capital, depreciation of plant, machinery, etc., about \$5 per ton, making the total cost of a ton of pig iron \$13.56. At Trollhättan, where there is abundant water-power, a much larger plant has been erected than at Domnarfvet. This plant was completed late in 1910 and has made a considerable quantity of pig iron said to be of exceptionally

good quality, containing only small percentages of sulphur and phosphorus. Since this furnace has been operating the weekly production of pig iron has been increased, the electrode and charcoal consumption has been decreased, and the power consumption has been reduced to an equivalent of only 1735 kilowatt-hours per ton of 2204 lb. of pig iron, at a cost of \$13 for the power. It is expected that the year 1912 will witness an extension of the Scandinavian electric smelting industry, four large electric pig iron furnaces of the Gronwall type having been planned for erection at Domnarfvet and Hagfors, Sweden, and at Tyassaa, Norway. Thus it seems that the future of the electric iron smelting industry in Scandinavia is fairly well assured. This is due mainly to the favorable conditions that prevail there. High-grade iron ore, carrying between 60 and 65% of metallic iron, is abundant, and electric power, developed from large waterfalls, is relatively cheap. There are no coal beds, and charcoal must be used for iron making. Charcoal is produced from the abundant timber, but the possibility of replacing two-thirds of the quantity required in iron making by electric power is a very important factor.

In the United States the only locality in which electric iron smelting has been attempted is in northern California. Here the physical conditions resemble in many ways those in Scandinavia, just described. No coking coal beds are near at hand, but timber for making charcoal is plentiful. Electric power is produced in excess of the demand from industries outside of iron smelting, but the water-supply is limited in summer and autumn. The pig iron market in San Francisco is favorable to a small local iron industry, since heretofore supplies have had to be shipped mainly from Illinois and Colorado, or imported from abroad. A Heroult furnace was erected in Shasta county for the Noble Electric Steel Co., and placed in operation in July 1907. This furnace is described by R. L. Phelps in the *Mining and Scientific Press*, July 20, 1907. It was designed to utilize 1500 kilowatts in the form of 3-phase current at 50 volts. The charge consisted of charcoal, limestone, and magnetite. The heat for smelting the ore resulted from the resistance of the slag, and charge to the current as it passed from the electrodes to the neutral point at the bottom of the furnace. At the start the electrodes were in slight contact with the neutral bottom of the furnace, but as the charge became heated the electrodes were drawn out of the molten iron and remained in the slag and charge. It did not fulfill expectations, however, the output never exceeding 11 tons of pig iron per day, and a second furnace, designed by Dorsey Lyon, was erected. This furnace was smaller than the first, being of 160 kilowatt capacity, and was designed to run with 4000 amperes at 35 volts, single-phase current. It differed considerably in design from the first one erected, and was started early in 1908, and made an experimental run for 46 days. The lowest power consumption reported to have been attained was 3066 kilowatt-hours per ton of pig iron. The output of the furnace was 2400 lb. of iron in 24 hours. In order to reduce this power consumption a larger furnace capable of continuous runs was next erected. This third furnace is built on the same general lines as the second, but has a capacity of 1500 kilowatts and employs 3-phase current. The charge is dried in a pre-heater which utilizes stack gases, and the charging is done mechanically. There are six electrodes arranged equidistantly around the furnace, and the current passing through the ore lying between them in the crucible melts the charge. The molten metal and the slag are drawn off as in ordinary blast-furnace practice. Charcoal for this plant is supplied by a wood carbonizing plant which has been erected near the furnace, and such by-products as wood alcohol, acetic acid, tar, and creosote oils are obtained. J. B. C. Kershaw gives a tabular summary of comparative costs of electrically produced pig iron, which follows, with the addition of dates.

With regard to the future of electric smelting of pig iron, there are certain controlling factors that will doubtless limit it to localities like Trollhättan and Heroult where all physical and commercial conditions are favorable to its development. The main point seems to be that the saving in coke

## COMPARATIVE COSTS OF ELECTRICALLY PRODUCED PIG IRON.

Date.	Type of furnace.	Location.	Power, kw-hr.	Estimated cost (2204 lb.)	Notes.
1903....	Stassano	Darfo, Italy	2,866	\$18.60	Power at \$9 per electric hp-yr.
1904....	Keller	Livet, France	2,589	13.27	
1906....	Heroult	Sault Ste. Marie, Canada	1,642	11.77	Power at \$10.71 per electric hp-yr.; ore \$1.50 per ton.
1908....	Gronwall	Trollhättan, Sweden	1,957	13.56	Estimate based on early trials.
1910....	"	"	1,735	13.00	Actual results obtained at Trollhättan, Sept. 3, 1911.
1910....	Heroult	Heroult, California	....	15.00	Power at \$12 per electric hp-yr.; ore \$1.50 per ton.

effected by the use of electric heating is so small that electric power must be produced or sold at a cost of \$8 to \$10 per electrical horse-power-year, a figure far below the possibilities of the great majority of hydro-electric power stations at present. The electric process is also further handicapped by the cost of carbon electrodes, an expense which the ordinary blast-furnace does not have to bear. These conclusions, it should be noted, have no bearing on the refining of steel in the electric furnace, a practice which is already established, and is rapidly expanding in Europe and America.

## Rubies and Ruby Mining

About a year ago some particulars extracted from a paper by Noel Heaton describing the method of making artificial rubies and sapphires by fusing alumina in the oxyhydrogen blowpipe were printed. It was stated then that the difficulty of differentiating between such a product and the natural stone was great. The Burma Ruby Mines company, the largest producer of the real article, commissioned Mr. Heaton to tabulate the points of difference. This chart is now being circulated by the company. The differences relate to variations of color, included bubbles, striations, inclusion of foreign matter, and 'silk'. As regards color, the natural stone often exhibits variations in different parts, the bands being either parallel or irregular; where as in the artificial stone the color is generally uniform, but when varied the bands are curved in outline. The bubbles contained in the natural stone are irregular in shape, often elongated and frequently angular; in the artificial stone they are generally perfectly round, rarely elongated, and never angular. Striations in the natural stone are perfectly straight or rectangular in outline; in the artificial stone they consist of a series of concentric curves. Inclusions of foreign matter in the natural stone consist of particles of various size arranged in an irregular manner; in the artificial stone they are small particles generally arranged in curves following the lines of striation. As regards 'silk,' this is a characteristic of the real ruby never reproduced in the artificial stone; it is due to a series of minute parallel canals arranged in three definite directions, giving a silky sheen by reflected light. The chart gives a number of beautiful colored illustrations based on microphotographs.

The Burma Ruby Mines Co. is once more on the list of dividend payers. It was floated 23 years ago by the Rothschilds to consolidate the ruby and sapphire mines at Mogok, Burma. The expectations of big profits were never realized, and not only have the dividends been small, but the capital has been reduced. Much larger amounts of money were required in order to bring the cost to a practicable level, and moreover the terms and conditions imposed by the Indian Government have been decidedly oppressive. During recent years the market for this class of stone has diminished, the diamond carrying all before it. The sapphire is not popular, as it is ineffective at night, and to the uninformed the best quality of garnet seems as satisfactory as the ruby. Moreover, the artificial ruby and sapphire have made inroads into the trade in the genuine article, and have penetrated even to the East. During the financial year ended February 29, the amount of gravel washed was maintained, 1,479,854 loads being treated at a cost of 7½d. per load, as compared with 1,466,136 loads the pre-

vious year. The sales in London were £10,236, and in Burma £48,551. In addition, £12,069 was received from tributaries. The sum of £10,862 was paid to the Indian Government as royalty, and also £2378 as share of the profits. The profit available for shareholders was £5256, and, adding £16,764 brought forward from the previous year, the disposal balance was £22,021. Out of this, £7475 has been paid as dividend, being at the rate of 2½%. The company has recently received a favor from the Government in connection with the item of £19,228 of arrears of royalty and rent. The payment of this sum is postponed until the net profits available for shareholders exceed 10% on the capital in any one year; in this case half the surplus is to be employed toward liquidating the debt. This lenient attitude was assumed by the Government because the company intimated a desire to develop additional ground at Kathie, six miles from Mogok. This work has now been commenced and is estimated to cost £20,000.

## Appropriations for the U. S. Geological Survey

LEGISLATIVE, EXECUTIVE, AND JUDICIAL ACT APPROVED  
AUGUST 23, 1912

Rents .....	\$37,400
SUNDRY CIVIL ACT APPROVED AUGUST 24, 1912	
Salaries, office of director.....	35,340
Salaries, scientific assistants .....	29,900
Skilled laborers and various temporary employees	20,000
Topographic surveys .....	350,000
Geologic surveys .....	300,000
Mineral resources of Alaska.....	90,000
Chemical and physical researches.....	40,000
Preparation of illustrations .....	18,280
Mineral resources of the United States.....	75,000
Gaging streams, etc.....	150,000
Books for the library.....	2,000
Geological maps of the United States.....	110,000
Surveying national forests .....	75,000
Engraving, printing, and binding monographs...	145,000
Total appropriation .....	\$1,477,920

## Depth of Kalgoorlie Mines

The Chamber of Mines at Kalgoorlie has compiled an interesting table showing the depths of the large gold mines in the state, as the following will show:

	Feet.
Associated .....	2,286
Chaffers (Main Reef) .....	2,274
Golden Horse Shoe .....	2,390
Great Boulder .....	2,845
Great Boulder (Edwards).....	2,879
Great Boulder Perseverance.....	2,200
Great Fingall (vertical and underlay).....	*2,516
Ivanhoe .....	2,660
Kalgurli .....	1,900
Lake View Consols .....	2,017
Sons of Gwalia (underlay).....	2,720
South Kalgurli .....	1,818

\*Depth of surface to bottom of winze from level 13.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Persistence of Ore in Depth

The Editor:

Sir—T. A. Rickard's interesting discussion of the subject of 'Persistence of Ore in Depth' presents certain facts now generally accepted by the geologist and the engineer, but not always admitted by the prospector and the promoter. It is with some hesitation that I have accepted the invitation of the editor to discuss the subject from the viewpoint of the economic geologist, because W. Lindgren has covered the subject in an early number of *Economic Geology* as far as the present state of knowledge permits, and the value of going over the subject in an incomplete and informal manner is not apparent. I shall attempt, however, to review a few of what seem to me the most important points bearing on this subject, and suggest the depth limits of a few of the most important groups of ore deposits. The discussion is largely theoretical, and I beg to suggest to those who want facts and not theories, that theory deduced from accurate observation has made it possible for the mining geologist to draw conclusions of decided practical value.

Probably the most fertile cause of inaccurate analysis of ore deposits is the lumping of all deposits together and attempting to apply the conclusions drawn from one type of ore deposit to an example of a second type different in origin and kind. The number of geological processes affecting ore deposition is large, and since any combination of these may modify a given deposit, the number of given results is increased in a geometric proportion.

At the outset, emphasis may be laid on a factor of importance bearing on the depth to which an individual ore deposit may extend. The outcrop of the deposit may be at what was originally the top of the deposit, or the present surface may cut the roots of the deposit. I have noted areas in Arizona and Sonora where the outer ore-bearing zone of a granite mass has been entirely removed by erosion, the original gold content being deposited in flanking detrital deposits. On the other hand, in the vicinity of the Gold Roads mine, Mohave county, Arizona, erosion has but cut the tops of the deposits, and there we may expect the maximum depth for the ore that is reached by deposits of its special type.

Theory again, but theory founded on established laws of physics, and checked up by the examination of rocks that have suffered alteration at some depth below the surface, limits the depth to which rock will sustain open fractures. Doubtless the strongest rock may be fractured to a depth greater than will be attained by mining operations, and, further, solutions under great pressure may open fractures that otherwise would be closed or would not exist, yet it is certain that the weaker, more pliable rocks, such as shale, etc., may form an effective bar to the passage of ore solutions. In the Oro Blanco district, Arizona, the ore-bearing andesitic rocks rest on shale, and the veins do not continue into this underlying formation. More important, however, is the fact that fractures become less numerous even at depths commonly reached in mining. Even in the Mother Lode district, where metallization has probably taken place at considerably greater depths than have as yet been reached by mining, there is no possibility that the orebodies are as numerous in the deeper levels as nearer the surface. At Cripple Creek, where decrease in tenor of ore at depths yet reached is denied by some, decrease in the number of orebodies is maintained by Lindgren and Ransome.

The theory of not so very long ago that ore solutions

originate somewhere and somehow at great but unknown depths, and rise along fissures that extend down indefinitely toward the earth's centre, incited the miner's imagination until he believed that the 'true fissure vein' had no bottom at all. However, more definite notions regarding the origin of various types of deposits suggest the grouping of certain of these in a broad way so as to bring out the limits as to depth to which a deposit of any group may be expected to extend under favorable conditions.

A great group of veins, examples of which have been found to attain unusual depth the world over, is the gold-bearing quartz group of lodes in granite or metamorphic rocks, including the Mother Lode type of veins in granite, between granite and slate, and in slate, greenstone, etc., the Alaska Treadwell type of breccia zones cemented by means of quartz veinlets, and the saddle reefs and veins in the Paleozoic slates of Australia, the quartz lodes and domes in the granite in Canada, probably the quartz reefs of the Rand, the Champion and neighboring lodes of India, etc. The theory is now held by many geologists that most, if not all, of these deposits were formed by mineralizing waters driven out by the crystallization of granitic magma. Field evidence suggests that the highly heated vapors given off while the intrusive is still molten do not develop ore deposits of this type, although they may metamorphose intensely the adjacent rocks. However, the 'liquid extract' driven off during the final stages of solidification is often immensely rich in gold content, and in extreme cases may cause a concentration in the rich gold-quartz which compared with the gold content of the parent granitic rock is represented by the ratio of 100,000 to 1. While this crystallization water may be excluded at considerable depths, forming bunches and lenses of ore, it could hardly get together in volume except in the zone of fracture, so that the bottom of the lode could not be formed at more than a few miles below the surface. The mineral constitution of the lodes is remarkably constant, and suggests that the ore shown in the outcrop, as well as that in the deepest levels, was originally formed under great pressure, so that probably erosion cut off from one to three miles before reaching the outcrops. These and other theoretical conclusions would fix the maximum depth of these deepest of veins at probably less than two miles, with the further probability that workable deposits more than a mile deep would be unusual. (Lindgren concludes that the range of these gold-quartz veins reaches 6000 to 7000 feet.)

While the highly heated vapors immediately accompanying the intrusive are not usually rich in gold, they form tin deposits, and contact deposits often carrying copper. First thought might suggest that tin veins formed at high temperatures and great pressures should be formed throughout a wide range of depth, but field evidence shows that when the tin deposits occur in the granite itself, the ore is found only in the upper and outer margin. This tin-bearing zone does not probably extend on the average over 1000 ft. within the granite mass. Where structural features are favorable for a concentrated flow of solutions, such as along contact between the granite and slate, or up into an overlying steeply dipping slate, greater depths may be attained, but not equal to those of the gold-quartz type.

Contact copper deposits without enrichment are not of sufficient value to be considered here, and while contact deposits may occur at any depths where calcareous rocks adjoin acid igneous masses, yet it is doubtful if those formed at higher temperatures are as rich in copper as those formed at lower temperatures and pressures.

The richest gold and gold-silver ores, as well as valuable gold-silver-lead deposits, are found in Tertiary lavas. A list of examples would include the greatest gold and silver mines of Colorado, Nevada, Arizona, Mexico, New Zealand, Transylvania, Hungary, etc. Without reviewing the evidence which topography, structure, mineral composition, and relation to superficial volcanic phenomena suggest, it may be stated that these deposits are far more superficial than the first class mentioned. Many highly productive mines of this class have 'petered out' at less

than a thousand feet, and it is unusual to have orebodies of this type extend to depths of 2000 feet.

The above discussion mentions only a few of the many types of ore deposits, and has had to do only with primary ores. Recent interest in secondary enrichment has overshadowed the fact that much of the rich gold and silver ore mined today has not been secondarily enriched. The importance of secondary enrichment in the concentration of copper, however, is so well known that it is only necessary to mention here that the zone of secondary sulphides varies greatly in different regions. It extends only a few feet below the water-level in some of the deposits of the Eastern United States. It varies between 50 and 200 ft. in the porous porphyry and schist of Arizona, but reaches down 600 to 1000 ft. where structural features assist downward percolation, and reaches a remarkable thickness of 2000 ft. and perhaps more at Butte.

It is hoped that the above brief paragraphs will indicate the change that has taken place with the scientific investigation of ore deposits, and instead of unlimited depth there are fairly definite zones of moderate depth beyond which ore deposition does not take place. The depths suggested are the maximum ones to which only the most important deposits attain. Each ore deposit is a problem in itself, and faulting, change in formation, evidences of a feeble rather than a strong widespread mineralization, etc., will be eagerly sought by the careful appraiser of the future possibilities of the mine.

Stanford University, August 30.

### A Few Words About Colombia

The Editor:

Sir—The chances for investment are wonderful in South America. I believe that Colombia will develop much quicker than anyone has any idea of at this time. The Panama canal, when finished, will help the great resources and bring to the notice of the world the vast wealth which is still undeveloped along the rivers, hills, and mountains. Colombia has an area of 450,000 sq. mi. and a population of between 4,000,000 and 5,000,000, of which 85% is made up of the working class or peons. Wages range from 60c. to \$2.50 per day, according to locality and climate; in the Zaragoza country wages are 50% higher than at Medellin. Naturally the peon expects more wages and does less work in the malaria district.

The Magdalena river, which runs north and south for a distance of about 1000 miles, and is navigable for 600 miles, is almost the only transportation route. One of the greatest drawbacks at this time is the high charge for freight. Another is the unreasonable duties imposed on imports; in fact the only thing that is cheap in Colombia is peon labor. The average American makes many mistakes in dealing with the native of South America. First, he should try and master the language, but still more important, he should study the character of the people. They are as sensitive as children, and should be treated as such. It is hardly reasonable to swear at them in English and at the same time ask them to do for you what they consider a favor. If they do not understand any other English, you may be sure they know all the American swear-words. In dealing with them, thank them, be kind, polite, but firm. Above all be patient, and you will be surprised what you can accomplish in much less time and for much less money than by pushing, swearing, and impatience. Never demand anything from a Colombian official, but ask for what you wish in a polite way, putting it on the basis of being a favor, and ten chances to one you will get what you wish. Do not be hurried in bargaining with the native and never pay him the first price he asks. After you have struck a bargain with him you can feel very sure he will carry out his part. Always keep your word exactly, and you will be surprised to see how anxious you will find the native to help you. Also, remember that your American dollar will not go as far in Colombia or buy as much as it will in the United States;

that at the present value the *peso* is only another name for a cent, or 100 pesos equal \$1. A five pesos piece looks very much like our five-cent nickel and has the same purchasing value in Colombia.

Among the things in which there is opportunity for investment in Colombia may be mentioned platinum, gold, silver, copper, salt, lime, asphaltum, oil, coal, emeralds, mahogany, cedar, ivory-nuts, bananas, cacao, coffee, sugar, rubber, corn, and cattle. Thousands of acres of land can be secured at low prices, both for agricultural or mining purposes. Quartz mining is still in its infancy, with the exception of three large mines which have been working and paying for years. The banking business is attractive, with loans at from 1½ to 3% per month. Capital is also invested by foreigners in Colombian railroads.

The climate is trying on the average foreigner. At the mouth of the rivers and lowlands, mosquitoes and, consequently, malaria are found. As to the cities, Bogota is too cold and Barranquilla too warm. The most desirable climate is at Medellin in the state of Antioquia. In all three cities the sanitary conditions are poor and danger of typhoid is great. Some of the richest dredging ground is situated in the malaria districts. The title to property should be carefully examined before purchasing, and only trustworthy and conscientious men should be sent to do business in Colombia. Nearly all the failures are due to mismanagement, extravagant engineers, and lying promoters. The state of Antioquia is rich in alluvial areas. Gold-bearing gravel is found adjacent to its many rivers. Those that have studied the mining possibilities of Colombia are impressed with the vast undeveloped wealth of its placers, and conservative capital is taking notice of the dredging ground as a business enterprise.

With the proper management, great care in regard to titles, strict compliance with the laws of the country, and above all—patience—remember it takes one year to do the work in Colombia that could be done in the United States in three months. I believe that any of the business chances in Colombia will prove profitable to the investor in the course of time.

L. M. LUDOVICI.

Barranquilla, Colombia, June 9.

### Peruvian Mining Regulations

Attention is called by the *West Coast Leader* to a circular letter sent out by the Department of Fomento, calling attention to the fact that the new code of civil procedure became effective on July 28, and that it affects the operation of the mining code to a certain extent. All who are concerned in pending litigation over mining property, or are, in fact, in any way connected with the denouncement or holding of mines, should secure a copy of the new law, and read article 1344, which nullifies paragraphs 2 and 3 of article 42 and chapter 16, with the exception of articles 198, 199, and 200, of the mining code, and any other stipulations which may be in disagreement with the new civil code. The paragraphs cited refer to the duties and powers of the mining deputations in lawsuits.

### Fluorspar Production

Last year the total quantity of domestic fluorspar reported to the United States Geological Survey as marketed in the United States was 87,048 short tons, valued at \$611,447, compared with 69,427 short tons, valued at \$430,196, in 1910, an increase in quantity of 17,621 short tons and in value of \$181,251. The production in 1911 was the largest ever recorded, 69,825 short tons of domestic gravel spar, valued at \$420,932, being marketed, against 52,013 short tons, valued at \$282,561, in 1910. The highly satisfactory condition of the fluorspar industry in 1911 was due largely to the ability of American producers to meet the demand more nearly than heretofore and to produce a better and more uniform grade of gravel spar than can be obtained by importation.—U. S. Geological Survey.

### NEW YORK

VACATION DAYS ENDING.—COPPER SITUATION.—DOME AND NIPISSING.—BUTTE & SUPERIOR.—BRADEN AND MINERALS SEPARATION.—TOMBOY.

New York is making the most of the last few days of the vacation season. There is no day in all the calendar that is now more universally observed than Labor Day. It has come to stand as the close of the summer holidays. The ocean-side resorts and the hotels of the lake and mountain regions which depend upon New York for patronage go into winter storage right after Labor Day, and the city in turn takes up its normal life of activity. The present week has been very much of a holiday period. Trading has been as nearly at a standstill as it can be. The metal markets are strong, but it is so nearly impossible to interest capital in new enterprises that, in spite of advanced prices, there are almost no new issues of any importance being offered to the public. The flotation of the Alaska Gold Mine Co. is an exception. This issue could not be classed as an appeal to the public for development funds. There has been a little trading in the stock in the outside market at a small premium above the subscription price. While copper is enjoying so much activity, and holders of copper securities are beginning to share in the prosperity in the way of resumption and increase of dividends, there is almost nothing doing in the way of new coppers. Whether there are no regions unprospected, or a lack of funds for grubstakes may be an open question, it takes new fields and untried possibilities to arouse public interest. The copper producers are, to all appearances, in stronger position than at any time since they got the market in hand. It is plain that the market is pegged around  $17\frac{3}{4}c.$ , and several of the largest sellers, including A. S. & R., the United Metals Selling, Phelps-Dodge, and others, report all September copper sold. There has been no marked activity on the part of buyers since June, but on the other hand there has been no selling pressure and no 'umbrella to hold.' Amalgamated is much of a market leader, and the predictions as to the company's future are many and varied. An increase in the dividend rate is expected. Anaconda is expected to declare a dividend at the rate of \$3 in September. If this income is in turn distributed to Amalgamated shareholders it will put Amalgamated on a 6% basis, as there are two shares of Anaconda held by Amalgamated for each share of Amalgamated outstanding. The idea that the latter is to be liquidated is not forgotten, but there are some things to be done. Cash and cash assets in Amalgamated's treasury are estimated as equal to some \$14 per share. At the time of the last report there was some \$15,681,000 cash on hand, against which there were outstanding the \$12,500,000 notes and some \$5,000,000 current accounts. Amalgamated, however, is a heavy holder of Greene-Cananea, and also of I. S. & R., both of which holdings now show a considerable profit.

The most interesting story regarding probable developments in the near future deals with the possible absorption of Greene-Cananea, North Butte, and Calumet & Arizona, all known as Cole-Ryan properties, and the Inspiration. The last named property has been developed to its present stage by W. B. Thompson, and while John D. Ryan is a member of the Board, it has hardly been classed in the Amalgamated group. The Inspiration board is one of immense financial strength and importance, and it would be a matter of great surprise if the property went into a merger as any kind of a tail-ender. Undoubtedly there are to be developments in Amalgamated, but No. 26 Broadway is always secretive, and more than apt to profit by the out-

siders' hazard as to what may happen if the said outsider takes any market position to back up his belief in the course of events. One fact of importance stands out above all others; the circle of the copper people with whom actual control rests is smaller than ever it has been heretofore, and while it is said, and is undoubtedly true, that there is no understanding as to prices, the same result is achieved by the elimination of competition. There is now no struggle between the Guggenheims and the Standard Oil crowd in copper. The Lake interests no longer hold themselves aloof. Interlocking boards of directors have worked wonders, with the result that the situation in copper is much as it is in railroads. No new developments of importance can be financed without the consent of the inner circle. The financial situation is so controlled that it is safe to say no unwelcome independent could carry through the development of a large new porphyry. No banker would extend aid to an outsider known to have the disapproval of the inside circle in copper for fear that his so doing might be construed as an unfriendly act. Copper is in a way to do big things when the legal path is cleared, but there is no longer any place for newcomers. There are independents such as Clark and Haggin, but

THE TOMBOY MINE, COLORADO.

these will find themselves without successors as they go. They are of an older generation, and achieved their present position before the science of combination was brought to its present state of perfection.

The Dome Mines, Ltd., the leading property in Poreupine, is stated to be earning at the rate of 20% on its share capital. Some of the most influential of New York financiers are interested in the Dome, notwithstanding which the shares were recently offered in the open market at \$20 per share and there was no bid. There has been a recent considerable advance in Nipissing, and there is some talk of a possible increase in the dividend rate. The company is just completing a mill to handle its low-grade ore, and after November 6 it is expected that all shipments will consist of fine silver bullion. The new mill is to be paid for out of earnings, and it is rather doubtful whether the dividend will be increased as expected.

Ambitious plans are being mapped out for the Butte & Superior. The company is now being referred to as the largest single zinc producer in the world, and with the addition of the new territory, which is to be taken on by the company, it is claimed that Butte & Superior will, within the year, be turning out one-half as many pounds of zinc per annum as Anaconda now turns out of copper. A much larger hoist is to be erected within the next two months. There is enough ore at the dumps to keep the mill going during most of the shut-down. When the new hoist is working, it is expected that the mill will be treating 150 tons of ore per day. It is a sign of improvement

in mining finance that, notwithstanding the sudden increase in value of the options secured by the Butte & Superior people, the options are being turned over to the company at cost, although they could be sold in the open market at a handsome profit.

The Minerals Separation Co., Ltd., is announcing the fact that the test work which it has carried on at the Braden Copper Co.'s property in Chile, South America, has proved so successful that the Braden people have decided to erect a plant to treat 3600 tons per day. The cost of the plant is estimated at \$15,000, and to put the plant on a 6000-ton basis would require only a nominal amount in addition. It is estimated that a plant such as is in general use would cost the Braden something over \$200,000, as compared with the cost of a plant using the treatment of the Minerals Separation Co. the cost of the latter is comparatively nominal.

The Barnes-King company has finally made arrangements to take over the ground of the North Moccasin at Kendall, Montana. The Barnes-King was at one time quite active in the New York market; later it was compelled to practically suspend operations, but having a considerable sum in its treasury, the directors have for some months been endeavoring to find a property that could be worked at a profit. The price agreed upon for the North Moccasin is \$150,000. A small payment is being made and the balance is to be paid by turning over 25% of the net earnings. The Tomboy is one of the American issues handled in London which has shown steady improvement during the past few months. The company is about to build a tramway from the Ophir tunnel to the railroad station. Surveys are completed, and work will begin as soon as bids from equipment builders are all in and contracts can be closed.

## BOSTON

ALASKA GOLD MINES OVERSUBSCRIBED.—COPPER MERGER TALK.—MARKET HOLIDAYS.—BUTTE REVIVAL.

The offering of Alaska Gold Mines stock by Haden, Stone & Co. here resulted in an oversubscription reported to be about tenfold. In Boston alone the stock was four times oversubscribed. The prestige of Hayden, Stone & Co. with porphyry coppers and Butte & Superior has availed the firm tremendously in bringing out this new Alaska low-grade gold issue. Charles Hayden, in this instance, for the first time in his successful banking-mining career, lends his name as president to a mining company. The stock has been listed on the New York Curb and will be traded in on the Curb here preliminary to applying for listing on the Stock Exchange. The trading in the stock on the Curb here pending the office subscription offering has been of considerable volume, in anticipation of the oversubscription which resulted.

The second instalment of 25c. per share on the stock of the Portsmouth Coal Mining Co., Henry M. Whitney's old Rhode Island Coal Co., is payable September 16. All stock which fails to pay will after 30 days be sold at public auction. On account of the criticism of the old management, which was charged with not having disclosed the tonnage which was claimed for the property, the Whitney interests are actively opening the property. This work will probably continue until next year. When the coal stock was first listed on the Boston Curb it was handled in a sensational market way and great expectations were raised. Since then the company encountered bad weather on the stock market, and now it is the Whitney policy to place the property in actual shape for big development before special attention is paid to the market end. Mr. Whitney's son is on the property at Narragansett, R. I., superintending operations.

In Boston there is a revival of the talk about the billion-dollar copper merger which was halted in 1909. It is said that the Morgan interests will underwrite the big combination and will formulate it precisely along the lines of

the United States Steel Corporation. The talk is that Anaconda will become the vehicle for carrying the merger through; that Amalgamated will be dissolved, and North Butte, Greene-Cananea, Calumet & Arizona, and Inspiration Consolidated will go into the concern. It is estimated that the Anaconda merger will control the production and sale of over 500,000,000 lb. of copper, one-third of the country's production. It is said that the Morgan interests, allied with Amalgamated and Standard Oil, have so developed their smelting and refining capacity, together with their selling channels, that they are now independent of the Guggenheims, who blocked the first merger plans. It is said that this group, through the Morgan house, which has also underwritten Alaskan Copper and railroad enterprises for the Guggenheims, will be able to dictate the terms of consolidation so as to gain the acquiescence of the Guggenheims. The merger will have its major interests in Butte, but will also be strongly entrenched in Bisbee, Globe, and Cananea, Mexico. It is believed here that J. P. Morgan & Co. can launch a copper merger which will successfully run the gauntlet of the Sherman anti-trust law. One feature of the move will be the passing of Amalgamated, of malodorous memory. Only the United States Steel Corporation investigation now remains in the way. Let the Steel Corporation get a certificate of good character and the copper merger will follow quickly. As the result of foreshadowing this immense consolidation, the speculative copper leaders are already showing great market strength. Practically all of the porphyries have reached high record prices and Amalgamated is selling around its high price of 1910 and considerably above that of last year.

Boston has more market holidays, perhaps, than any other Stock Exchange city in the Western Hemisphere. Perhaps London may rival the 'Hub' in the number of its holidays. For Labor Day the Boston stock market closed on the Saturday before as well. Boston observes all of the New York Stock Exchange holidays, and still others during the year which are not legal elsewhere. There are a number of men and events in New England which require canonization and anniversaries, and Boston honors these in the observance rather than the breach. An Eastern visitor to Butte last spring said he met a number of local traders in the board room of Paine, Webber & Co. who inquired the reason of so many holidays in the Hub at that season of the year. They could keep track of the national legal holidays on the calendar, but were unable to do so with reference to all of the days which Boston observes. When they saw the bulletin marked up on the blackboard, 'Market holiday in Boston,' at times it was as foreign to them as the announcement of holidays which are local to London.

The interest in Butte has reached a high pitch in Boston. A gentleman of the cloth, who has recently returned from Butte, describes the district as having a 'rebirth.' In addition to Butte & Superior, the probability that North Butte has again opened the Edith May vein on the 2400-ft. level, and the opening up at depth of copper ore by the Davis-Daly and Butte Central, point to Butte becoming a far bigger camp than its fondest friends have ever dreamed. A prominent financial paper in the East points out that Butte mines, being in the granite formation, may be likened to the famous Rio Tinto, whose history can be traced back in a semi-authenticated manner to the eleventh century. There has been a great upsetting of opinion in Boston as to the possibilities of Butte and even essential revisions of the technical findings announced in early geological reports. The time was when the Speculator mine of the North Butte was considered to be the *Ultima Thule* of the district's mineralization, but now active prospecting is going on 2½ miles north of the Speculator. Another recent visitor to Butte states that no shaft has been sunk 1500 ft. in the district without going into a property worth anywhere from \$1,000,000 to \$50,000,000. The names of old wild-cats and abandoned silver mines are paraded in print again, and the strange part of it all is that they

are now being acquired by men of heavy capital. The expansion of Butte in width and depth of mineralization, and the various metamorphoses going on there in the personnel of interested capital, are phenomena of the most sensational character in mining annals.

There is nothing but praise here for the method finally adopted of increasing Butte & Superior capitalization to take up the options on property to the north which were tied up by Butte & Superior principals. At first the idea was to create an independent company to take over these outlying prospects and give Butte & Superior stockholders an opportunity to subscribe at ground-floor figures. But the point was made that all Butte & Superior stockholders, regardless of further subscriptions, would become the beneficiaries of information gained through the exploitation of Butte & Superior, and that the formation of a new company would be unfair to them. So the interests in charge chose the better plan of enlarging Butte & Superior capitalization to meet the situation.

### BLACK HILLS, SOUTH DAKOTA

BLACK HILLS STANDARD MINING CO.—RUBY M. CO.—HOMESTAKE COMPANY BUYS THE HIDDEN FORTUNE.

The annual meeting of the Golden Reward Co., held recently at Deadwood, resulted in the election of the following directors: A. G. Hackstaff, O. H. Kahn, Harris Franklin, Robert W. Goelet, George D. Dewitt, Henry W. DeForrest, W. B. Devereux, and Walter Lutgen. The officers will be elected at a meeting of the directors which will be held soon at New York, and will undoubtedly be A. G. Hackstaff, president; Harris Franklin, vice-president; C. C. Tegethoff, secretary and treasurer, and N. E. Franklin, of Deadwood, South Dakota, assistant secretary. At the meeting 692,448 shares were represented, of a total issue of 1,000,000 shares. The Black Hills Standard Mining Co. is the newest corporation in the Black Hills, having just been organized to take over the property of the Deadwood-Standard and Spearfish companies, and the adjoining group, known as the Slavonian ground. The 100-ton cyanide plant at the Deadwood-Standard has been overhauled and has started work, handling ore from that property. As soon as possible the company will open the Slavonian group, where there is a good showing of ore. It is across the gulch from the mill. The officers of the company are John Gray, president and general manager; Paul Rewman, secretary and treasurer; and Edward Manion, superintendent. All are successful Black Hills miners and operators, and other people interested in the concern are practical men of local experience, so that it is safe to predict a success for this company. The ore occurs in the Carboniferous limestone and is easily cyanided. Dry crushing is the process in use. The Ruby Mining Co.'s annual meeting resulted in the election of the following directors: Mrs. James Conzette, president; Arthur M. Hanna, vice-president; Norman T. Mason, secretary; and Rollin Maxam, treasurer. The company owns property in Ruby gulch, Galena district, which shows a large body of porphyry gold ore.

The Homestake company has started work on a building to be known as 'Recreation Hall,' which, as its name suggests, will be used as a gathering place for employees. It will be fitted with a large hall, for public gatherings, club-rooms, lounging rooms, gymnasium, and baths, and will in fact be an up-to-date club-house, built, supported, and fostered by the Homestake company, but managed by a board of directors elected from among the employees. The building will be on Main street, Lead, next to the Hearst Free Kindergarten, and Christ church, which property, in turn, adjoins the government building. The Homestake has recently installed a 150-hp. electric-driven Ingersoll-Rand air-compressor to eliminate steam power in the machine shop and foundry. Repairs are being made, under the direction of George Morthland, at the flume from Little Elk creek, which supplies a portion of the water for the Homestake. The flume is in bad condition, but will be practically

rebuilt, and vitrified tiling used in some places. The Homestake company is now the owner of the Hidden Fortune property, having acquired it from the trustee at a price of \$51,000. This amount represents labor and supply liens, receiver's fees, and taxes. The latter item was the largest, amounting to practically \$34,000. The property totals 300 acres, and adjoins the Homestake on the west and northwest. This is the final chapter in the history of a property that a few years ago was the basis of a company capitalized for \$5,000,000, with stock peddled broadcast over the United States at from 50c. to \$2.50 per share. After two years of fancy financing and manipulation it became the object of litigation, and operations were suspended six years ago. A mill was erected three miles from the mine, on the Northwestern railroad, but it is stated that the Homestake company will not use it.

The New Reliance company has paid off its indebtedness, amounting to \$14,000, and started the mill. The plant is equipped with 30 stamps, Dorr classifier, sand-leaching tanks, and treats the slime by agitation and decantation. Directors of the Hidden Treasure company, elected at a meeting held at Deadwood, are: S. T. Cochran, president; J. N. Andrews, vice-president; R. S. Grimes, secretary; Banks Stewart, treasurer and general manager; Nate Hart; and J. P. Knowles. A contract will be let for about 200 ft. of driving, following a showing of fluorspar which carries argentiferous galena.

### MELBOURNE, AUSTRALIA

BRITISH BROKEN HILL.—NORTH NUGGETY AJAX LITIGATION.—ANOTHER VICTORIAN SCANDAL.—MT. LYELL.—BROKEN HILL PROPRIETARY AND THE IRON BUSINESS.

In my last letter I dealt with the scandal in connection with the management of the locally controlled Victorian mine, the North Nuggety Ajax; today I have to speak of an English-governed mine whose scene of operations is in New South Wales. This is the British Broken Hill, a mine which has had within the past twelve months or so a remarkable rise in its share-value by reason of the proving of a vast body of ore reckoned to turn it into practically a new mine. After its dashing uprush, it came down like a stick when news came that it was proposed to issue 75,000 new shares at 50s., one-fifth of these to be held in reserve. In face of that fact it is hardly likely that the shares would retain their price of 62s. The unpleasant feature of the business is the ignorance in which the Australian shareholders have been kept. It is a constant complaint here that London Boards act without any consideration of Australian holders, and this is but another instance of the fact.

Regarding the North Nuggety Ajax Co., an interim injunction has been granted against the acting directors, the Victorian Chief Justice deciding that the action of the chairman of the general meeting of shareholders in the company, in refusing to accept a motion dissenting from his ruling, and declaring the meeting closed, was illegal. The way is now clear for the hearing of the main case, which provides for the acknowledgment of the two directors chosen by the general body of shareholders after the chairman had left the meeting. The very discreditable circumstances connected with recent development in the property of this company have been followed closely by a scandal in connection with another Victorian mine. This is an alluvial gold concern, the New Langi Logan, at Ararat. Shares dropped from 19s. to 17s. 6d., and then a wire was received by the company's secretary in Melbourne to this effect: "Bore through to clay at 77 ft." The wire was posted and taken to mean that, having failed to locate wash, the bore had been discontinued in clay; with the result that values receded to 13s. 9d. The same day, however, strong buyers came in, and prices rallied to 16s. The next morning a wire came through from the mine manager as follows: "Continued bore and went through to heavy water-worn wash at 87 ft. Wash resting on given reef, carrying gold. Still boring in strong wash." Prices at once advanced to 21s. It is obvious that some one knew that the

facts were not as the first telegram implied; and inquiries have been instituted as to the source of that wire. The mine manager has acknowledged that the earlier wire was from him, and explains that he thought the bore was through into clay, but that on continuing it he found the clay to be but a thin layer. The explanation leaves much yet to be explained.

At Mt. Lyell, Tasmania, production is getting back to the normal, the North Lyell mine producing 9000 tons per month, and the Mt. Lyell nearly 5000 tons of pyrite per week. The total number of men employed in the two mines is nearly 900, or over 1000 in excess of the number employed in this department of the company's operations twelve months ago, so that it is not surprising that mining costs increase. The total number of men at the mines and smelters is, however, about 100 less than twelve months ago, so that the increase at the mines themselves is more than compensated for in other directions. The total number of the company's employees in the Lyell district is approximately 1500.

In connection with the proposal of the Broken Hill Proprietary to go into the manufacture of iron and steel, David Baker, of Philadelphia, Pennsylvania, has made a favorable report upon the project; and it has been confirmed by Mr. Delprat. An extraordinary general meeting of shareholders is to be held on September 27, when a proposal will be put forward for the creation of 340,000 new shares of 8s. each, fully paid (thus raising the number of shares to 1,500,000). Another extraordinary general meeting will be held to obtain consent to the enlarging of the process of the company so as to permit of engaging in all the branches of business of an ironmaster, after which the sanction of the Supreme Court of Victoria will have to be obtained.

### HOUGHTON, MICHIGAN

LAKE SUPERIOR MINING INSTITUTE MEETING.—EXCURSIONS AND PAPERS.—MINING WASTE AND BUREAU OF MINES.

The seventeenth meeting of the Lake Superior Mining Institute was held at Houghton the last week in August, with F. W. Denton presiding. Wednesday was spent in an excursion to the South Range, taking in the Michigan smelter of Copper Range Consolidated and the mines of the same company near Painesdale; in the evening a business meeting was held at Houghton. On Thursday there was a trip to Calumet and points north of Portage Lake, followed by a dinner at the Onigaming Yacht Club in the evening, with a concert by the Calumet & Hecla band. A business meeting was held on Friday morning and the afternoon was spent at the Michigan College of Mines. A number of interesting papers were read, several being by members no longer residing in the Lake Superior district, including one by Benedict Crowell, of Cleveland, on 'Methods of Sampling at Lake Superior Iron Mines'; by Alfred C. Lane, of Tufts College, on 'The Unexplored Parts of the Copper Range of Keweenaw Point'; and by O. P. Hood, of the Bureau of Mines, on 'Balancing Rock Crushers.' Particular interest was manifested in 'Applications of Concrete Underground,' read by H. T. Mercer, mining engineer for the Copper Range mines, as this subject has been discussed considerably at meetings of the Copper Country M. C. M. Club; also in 'The New Franklin Hoist,' by R. H. Corbett, as the hoist in question uses the weight of a descending skip to store energy in an air-compressor instead of the more usual method of counterweighting. Two interesting shaft-sinking papers were presented by E. N. Cory and S. R. Elliott, both of Negaunee. The shafts described were sunk about a mile apart in the Negaunee basin, the first by the Jones & Laughlin Co. and the second by the Cleveland-Cliffs Iron Co. The Jones & Laughlin shaft was raised, enlarged, and timbered in old-fashioned style by nine men, who did their own tramming and timbering; the Cleveland-Cliffs shaft was sunk and concreted throughout along modern lines by a larger force and at much greater expense. F. W. Sperr's talk on 'Mining Methods' was well received. In addition, the following pa-

pers were presented: 'System of Safety Inspection of the Cleveland-Cliffs Iron Co.,' by William Conibear, Ishpeming; 'Mine Sanitation,' by E. B. Wilson, Scranton, Pennsylvania; 'Foot-wall Shafts in Lake Superior Copper Mines,' by L. L. Hubbard, Houghton; 'Rock-House Practice of the Quincy Mining Co.,' by T. C. DeSoller; 'Construction of Intakes at the Mills of the Champion and Trimountain Companies,' by Edward Koepel, Beacon Hill, Michigan; 'In the Lake Superior Area—What Influences, if Any, Did the Ancient Topography of Footwall Beds Have Upon the Subsequent Disposition and Distribution of Copper in Overlying Beds?' by L. L. Hubbard, Houghton; 'Notes of Methods of Mining Ore in the Lake Superior District,' by F. W. Sperr, Houghton; 'Failures of the Rule of Following the Hanging in the Development of Lake Superior Copper Mines,' by F. W. Sperr, Houghton.

Among the visiting members were: J. A. Holmes, director of the Bureau of Mines; William A. Paine, of Boston, president of Copper Range Consolidated; Thomas F. Cole, W. G. LaRue, J. H. Hearding, of Duluth; E. P. Ryan, of Mexico City; H. O. Young, of Ishpeming; J. M. Longyear, of Brookline, Massachusetts; F. M. Prescott, of Milwaukee; and S. L. Mather, of Cleveland. Mr. Holmes, of the Bureau of Mines, gave a brief address following the dinner at the Onigaming Club; he dwelt upon the breaking down of barriers effected by the Institute, pointing out the change from conditions of twenty years ago when one mine scarcely knew what another was doing. The Bureau of Mines, he stated, wanted to gather all the information possible regarding conservation of life and resources in mining, in order to give it out through channels where it will do the greatest good. "Company secrets are not wanted, and the Bureau refuses absolutely to have relations with the courts. Its officials have been called upon to testify in case of mine accidents where Bureau investigations have been made directly after the catastrophe, but they have steadfastly refused to comply, and have been supported in this by the attorney general and the courts themselves." It was stated, concerning metal mining, that the first appropriation for this branch was made this year, the amount being \$50,000, which is entirely too small for the work the Bureau would like to accomplish. Regarding the conservation of resources, Mr. Holmes said: "Exhaustive research has shown that the Western hemisphere has very little real coal either north or south of the United States. If this country can export coal to South America in exchange for the products of that continent which we need, great good will be accomplished. To this end it behooves the coal operators to save the 250,000,000 tons of coal wasted yearly by bad mining, a half ton being wasted for every ton extracted. The yearly waste of natural gas is greater than the total yearly consumption of manufactured gas in all plants of the country." Mining officials present gave strong endorsement to Dr. Holmes' views and testified personally to the benefit derived from the work of the Bureau, as well as the value of its publications. As a result of Dr. Holmes' visit, the Institute has appointed a committee to coöperate with the Bureau.

At the dinner, also, there was some further discussion of safety appliances and regulations, which was closed by M. M. Duncan with a graceful compliment to the methods followed in the copper country, the success of which he said the iron mining companies, under the stress of difficult circumstances and conditions, were striving to emulate.

At the election of officers held at the Michigan College of Mines, the following were elected for the ensuing year: president, Pentecost Mitchell; vice-presidents, F. J. Webb, A. D. Edwards, and W. B. Chiun; managers, G. S. Barber, W. H. Johnston, and C. H. Baxter; treasurer, E. W. Hopkins; secretary, A. J. Youngbluth. While the place at which the principal sessions of next year's meeting will be held has not been decided, the Mesaba range will be the district to be visited. The secretary reported 286 members, 27 of whom had been gained during the past year, and 70 applications of membership yet to be acted on. Resolutions of respect to the memory of the late Graham Pope, of Houghton, a former president of the Institute, were passed.

## General Mining News

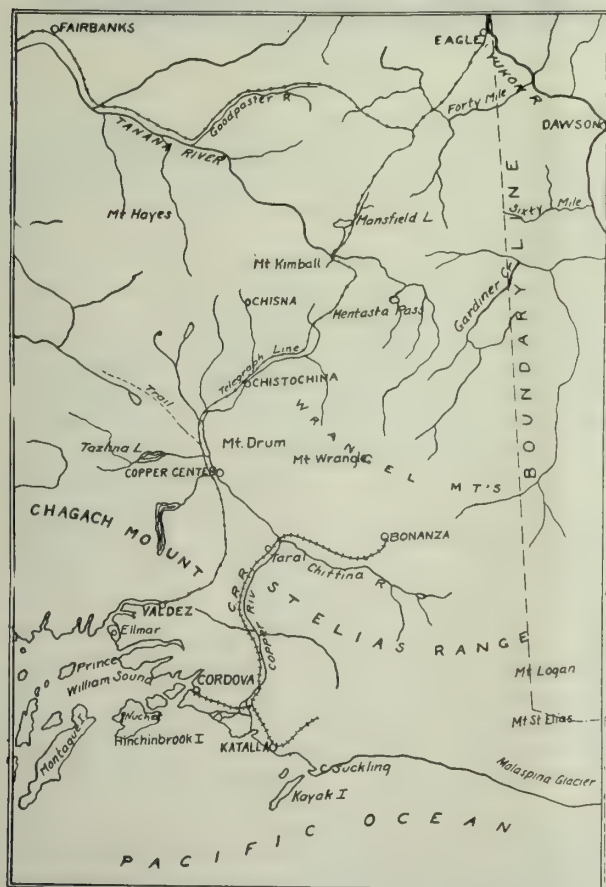

### ALASKA

#### CORDOVA

There is a good deal of activity being shown in the White river country, in staking claims and development, near Scolai pass, and along the foot of Scolai and Russell glaciers. It is reported that \$200,000 has been paid for a group of copper leases. Surveyors are at work 300 miles from Haines Mission, through the Alsac country, to the headwaters of the White river, near the rich coal deposits on Rabbit and Boulder creeks. Men are working on both sides of the boundary line, and get supplies from Dawson at a cost of 75c. per pound. Besides this, there is a duty of 20 to 60% on foodstuffs originally from Seattle or San Francisco. It costs a prospector from \$1500 to \$2000 a year to live in the White River country. Efforts are being made to have a trail from the American side.

#### FAIRBANKS

The Koyukuk river has been very low. The steamer *Reliance* brought down \$150,000 in gold dust from the

MAP OF CORDOVA-FAIRBANKS REGION.

Koyukuk camp. Considerable gold is being found at Hammond from deep diggings, but costs of recovery are high. A nugget, containing gold worth \$280, was found in the sluice-boxes at the Morrison bench claim, known as 21 Goldstream. Gravel from \$10 to \$48 per pan has been found at Noeller and Gustasson's claim, on Three Below, Fairbanks creek. A \$20 nugget was picked up. At present 23 men are working on the claim.

#### JUNEAU

During July the 120-stamp mill at the Alaska Mexican worked 29.75 days with water-power, and crushed 19,824 tons of ore, with a yield of \$29,547 from free gold and \$33,895 from 402 tons of concentrate, making a total of \$63,442. Operating expenses were \$24,847, and construction \$4921, and the net estimated profit \$33,039. The yield

per ton milled was \$3.20. Development covered 206 ft., and the stock of broken ore increased 16,133 tons. At the Alaska United, the two 120-stamp mills worked 29.67 days, crushing 37,450 tons of ore, producing free gold worth \$53,409, and \$57,060 from 861 tons of concentrate, the total being \$110,469. The average yield from the Ready Bullion mine was \$3.56 and from the 700-Ft. Claim \$2.81 per ton. The total estimated profit was \$53,943. Development work in the Ready Bullion covered 175 ft., and in the 700-Ft. Claim 284 ft., the stock of broken ore in the former increasing by 10,226, and decreasing in the latter by 1048 tons.

#### NOME

Four of the new dredges brought here this season are now at work, and several more may begin before the freeze. Work generally has been helped by a good fall of rain during the week. The last steamer this season for Nome left Seattle on September 2.

#### VALDEZ

Heavy rain during the past 10 days, the breaking of a glacier on the line of the Copper River & Northwestern railroad, together with high tides and heavy inshore wind, have caused a wash-out of 20 miles of the line. Traffic cannot be resumed for 30 days.

### ARIZONA

#### GILA COUNTY

(Special Correspondence.)—After September 1 the wages of all underground employees in the mines of the Globe-Miami district will be increased by 25c. per day, as the result of a recent conference of the mine managers of the district. After that date the minimum rate will be \$3.75 per day of eight hours instead of \$3.50 which is paid at present. The mines affected include Miami, Inspiration Con., Old Dominion, and others. Churn-drill hole No. 8, at the Southwestern Miami, is 880 ft. deep and still in chalcocite-bearing schist. It is being enlarged with a 6¼-in. under-reamer. Holes No. 6 and 7 are 905 and 885 ft. deep, in schist, respectively. About 500 men are employed in development and construction work at the Inspiration Con. mines.

The concrete lining of the 2-compartment Kingdon shaft of the Old Dominion mine has been completed from the collar to the bottom, a distance of 1017 ft. This shaft will be used for ventilation and for the men working in the eastern end of the mine. The work was done under contract by Paul Michaelson and C. H. Weideman. Churn-drill hole No. 3 of the South Live Oak Development Co. is 285 ft. deep in silicified schist carrying oxide, silicate, and carbonate of copper in small amounts. The White Metal Development Co., of Globe, is cleaning out the 200-ft. level of the old McMorris silver mine, 8 miles north-east of Globe. The work is slow and difficult, as the drifts have caved badly, the mine having been closed down about 30 years. A shoot of good smelting ore 4 ft. wide has been opened up on the 650-ft. level in the Williams shaft of the Iron Cap mine, about 125 ft. east of the shaft. It consists mostly of soft hematite and is estimated to average 8 to 10% copper, which occurs as oxide and carbonate. The west drift on this level is also being advanced. The Gibson mine, 9 miles west of Miami, continues to make steady shipments of chalcopyrite ore, averaging 16% copper, to the Old Dominion smelter, and shipped four cars in August. The ore is nearly all coming from the fourth level on the Pasquale vein, though a small amount is taken out in the progress of driving south on the fifth level, which is in 170 ft. and in which small stringers of ore are being found. Five or six stopes are being worked on the fourth level, one of which is 9 ft. wide and carries several shoots of shipping ore. It is proposed to soon begin driving on the sixth level. About 30 men are employed.

Globe, August 29.

#### GREENLEE COUNTY

Basic brick has arrived at the Arizona Copper Co.'s

smelter, and will be tried in the converters. This process is in successful use at the Cananea Consolidated and the Calumet & Arizona. During the half-year ended March 31, the Arizona Copper Co. produced 9073 tons of bessemer copper. Gross profits were \$850,215; capital outlay was \$249,000, of which \$150,000 was spent on new plant. High-grade ore is being shipped from the New York & Arizona company to the smelters. The mill and cyanide plant are not working at present, but it is intended to erect a tube-mill later on.

## CALIFORNIA

### CALAVERAS COUNTY

The Poorman mine, near Glencoe, which has been shut down for 30 years, has been bought by Pennsylvania capitalists. This mine was originally worked by Lewis brothers, who are reported to have taken a good deal of gold out of it to 140-ft. depth. Some rich gravel is being worked by R. King at the Three B mine on the Calaveras river.

### EL DORADO COUNTY

(Special Correspondence.)—The Atwood Mines Co. is arranging to develop the recently acquired Secombe & Jones group. It is stated the first payment on the purchase price has been made. A. W. Tennant is manager. Tennant and associates are also interested in the Martin mine, Grizzly Flat district. A stamp-mill may be erected at this mine later on. Indianapolis capitalists are contemplating resuming work at the Grand Victory. This mine was formerly a noted producer, but has been idle about twelve years. The equipment includes a 60-stamp mill. John C. Wright is heavily interested. It is stated that George M. Clark will probably be placed in charge of operations.

Placerville, August 31.

A suit has been brought by the owners of the Georgia Slide mine against the directors of a company which leased the mine last October, to recover \$750 alleged to be due under agreement giving to the owners 25% gross of the gold taken from the mine. In addition, the mine-owners sue for \$250 for time and money spent to recover the royalties. According to bullion receipts, \$6572 was realized by the Georgia Slide Mining & Milling Company.

### SAN BERNARDINO COUNTY

The Golden State Mining Co. is developing claims in the Whipple Wash district. The veins are said to yield from \$10 to \$100 per ton at the surface, by panning. In the same district, the Kansas City Mining & Milling Co. has built a 40-stamp mill for custom work. It will be ready early in September.

### SAN DIEGO COUNTY

It is reported that there has been a revival of mining in the old Campo district, fifty-five miles southeast of San Diego, and within three miles of the Mexican border. Gold has been found on 27 claims, and Utah and California men are developing the property, which is called the Lost Alice, after the Alice claim, supposed to have been worked by a Scotchman about 200 years ago. In fact, it is stated that one of the earliest discoveries of gold ore within what is now the United States, was made here. There are three veins on the Lost Alice being opened by shaft and adit. In a recent find, an 18-in. vein was exposed, and a 3½-in. streak assayed very high. Nineteen pounds of ore gave 3.4 oz. of bullion. There is plenty of water on the property.

## COLORADO

### GILPIN COUNTY

The shaft of the Wild Cat company is now down 100 ft., and levels will be driven east and west. A local pool is developing the Homer lode, on Central hill. An adit has been driven 200 ft. on Shanks lode on Quartz hill, and a width of about 5 in. of ore returns \$50 per ton. From the National tunnel 72 tons of ore was shipped to the Iron City mill, returning 18 tons of concentrate worth \$15 per ton. The lode is 4 ft. wide, and a 25-ton sample has been sent to Idaho Springs for testing purposes. Eight

tons from the War Dance mine yielded \$161 per ton at the smelters.

### OURAY COUNTY

From a report issued on the operations of the Camp Bird mine, it appears that, at June 30, the amount of dry ore broken in the stopes had been reduced to 1152 tons; but active development was to be undertaken with a view

CAMP BIRD MINE.

to reaching the rich ore recently found in deep ground between levels four and five. At the Santa Gertrudis mine, in Mexico, development continues satisfactory, and additions to the mill, to increase its capacity, will be completed by November.

### TELLER COUNTY (CRIPPLE CREEK)

According to local statistics, the output of the Cripple Creek district for August was 75,326 tons of ore, with a gross value of \$1,193,515. As compared with July, the tonnage and the gross value is slightly less than of last month. This in part is due to the temporary suspension of work in several of the local mills. The reports made by the heads of the various mills follow:

Mill.	Gross tonnage.	Average value.	Gross bullion value.
Golden Cycle .....	32,000	\$20.00	\$640,000
Portland .....	10,000	22.00	220,000
Portland (Cripple Creek dist.)	15,300	3.10	47,450
Independence .....	9,926	2.76	27,395
Joe Dandy .....	1,950	2.10	2,940
Wild Horse .....	1,100	2.40	2,640
Isabella .....	700	1.20	840
Gaylord .....	500	4.00	2,000
Smelters .....	3,850	65.00	250,250
	75,326		\$1,193,515

It has been decided to use the water flowing from the Roosevelt tunnel for generating power, and T. R. Countryman has been instructed to prepare plans and estimates of the horse-power that can be developed, and submit to the tunnel company. For the first 15 days of August there was a marked recession of water in the Gold Coin shaft, but since then it has risen 2 ft., due to seepage.

During a stoppage of the Golden Cycle pumps for two days, water rose in the Vindicator shaft above the 1600-ft. level, but work has since been resumed at this point. The water zone, in which these two mines are situated, seems to be out of that section drained by the Roosevelt tunnel, so it is necessary to pump. Eight machines are now working in the Modoc mine, on Battle mountain. Ore from levels 7, 9, and 13 is being shipped to the Pueblo smelter. The Blue Flag mill has started work again after three months' stoppage for repairs. The changes are said to include some improved leaching process.

## IDAHO

### COEUR D'ALENE

On September 4, the Bunker Hill & Sullivan company

paid dividend No. 180, amounting to \$65,400, making the total to date \$13,715,550.

#### IDAHO COUNTY

The Mineral Zone mine has been sold to Philadelphia men for \$100,000, by Mrs. M. A. Parr. The ore is said to assay \$30 per ton. The Buster mill has been leased by the new company.

#### JUAB COUNTY

Shipments from the Tintic district for the week ended August 30, totaled 231 cars of ore, the Centennial-Eureka sending out 46 cars; Iron Blossom, 30; Chief Consolidated, 26; and Mammoth, 24. The matter of zinc ore freight rates has not been settled yet, so shipments are being held back. It is said that the Chief Consolidated is in a strong financial position, and a dividend ought soon to be paid. About 100 tons of copper ore is being mined per week on the 600-ft. level of the Iron Blossom mine.

#### SUMMIT COUNTY

During the week ended August 31, Park City district mines shipped 1550 tons of ore. Thirty expert drill-men arrived at the Daly Judge, where they have a contract, under J. A. McIlwee & Sons, of Denver, to drill for this company and the Daly West.

### MISSOURI

#### JASPER COUNTY

The Granby company of Joplin is starting a big drilling campaign, and nine drills will be set at work. Three churn-drills are to work near former workings of the Granby camp; while two, which are stationed to the south and east, are in unprospected territory. Two other drills are at work in isolated regions between Granby on the southwest and Duenweg on the northwest. Surface indications at this point are said to be encouraging; but no mining has so far been undertaken. The two other machines are drilling at Oronogo and Chitwood, respectively. The weekly output from the properties of the Granby company is about 350 tons of blende, 200 of calamine, and 50 tons of lead. From the Granby and Spring City lands comes the bulk of calamine production. Drilling on the Chitwood tract is of importance, as it is the initial step looking toward mining operations by the land-owning company in this district. Hitherto all the production has come from leasing companies.

### MONTANA

#### BEAVERHEAD COUNTY

(Special Correspondence.)—Local men are preparing to drill for oil in the shales six miles south of Dillon. Oil-bearing strata have been known there for years, but so far no systematic development has been attempted.

Dillon, August 23.

#### LEWIS AND CLARK COUNTY

In a circular to the stockholders of the Barnes-King Development Co., C. W. Goodale, president, states that the company has purchased the North Moccasin property, which covers 2000 ft. in length along the formation between the Barnes-King on the north and Kendall on the south. The price of the new claims is \$150,000, and \$5000 will be paid in cash, the balance out of net profits of mining operations, within no stated time. From each month's yield the Barnes-King is to retain \$3.50 per ton and pay 75% of the balance to the North Moccasin people, until the above-mentioned price has been paid. From the latter claim, 25,000 tons of ore produced bullion worth \$127,000. It is proposed to repair the Barnes-King shaft and open the North Moccasin by an incline which will be sunk under the lode from the 400-ft. level of the former mine. It is expected that mining and milling costs will not exceed \$3.50 per ton. The Piegan-Gloster property has also been secured, under terms, for \$125,000. It includes 200 acres and covers 9000 ft. along the Piegan-Gloster vein. The old Gloster mine was opened to 500-ft. depth in 1888, and produced considerable bullion. The Piegan claim has yielded 10,000 tons of ore, and the present reserves are 23,000

tons worth \$8.50 per ton. G. T. McGee, formerly manager of the Barnes-King, has been appointed to take charge of the new ventures. The directors state that 100 mining properties have been considered during three years. In the suit of the Western Development Co. of Arizona against the Barnes-King for \$97,000, the first hearing was in favor of the latter. Plaintiff appealed, and the Circuit Court of Appeals overruled the previous decision, sending the case back for trial on the complaint, which is now pending. In the case of Killen v. Barnes-King, for personal injuries, the former got a verdict for \$5000. An appeal has been lodged against this. The financial statement of the Barnes-King company shows that cash in various banks amounts to \$207,655, and bonds of \$54,764, drawing 4% interest, are held.

#### FLATHEAD COUNTY

(Special Correspondence.)—Kalispell capital has been secured to drill for oil in the Tertiary beds southwest of the town. Some oil and gas were found there last spring in a well which was being drilled for water.

Kalispell, August 23.

#### JEFFERSON COUNTY

(Special Correspondence.)—John D. Pope, manager of the North Butte company, and G. W. Wilson, both of Butte, have organized the Mount Washington Copper Co., to operate the Fred Kauf property near Wickes. The company is capitalized at 100,000 shares, par value \$5. This property lies between the Blue Bird, Pen Yan, and Alta mines. The ore consists of silver, lead, and gold. An electric hoist is being erected, as well as the necessary buildings.

Butte, August 23.

#### MISSOULA COUNTY

(Special Correspondence.)—British Columbia smelting interests are said to have purchased the Monitor, Richmond, and Log Cabin groups, near Saltese. Active development is to begin at once.

Missoula, August 23.

#### SANDERS COUNTY

(Special Correspondence.)—Nearly all the machinery for the hydro-electric plant on Prospect creek has arrived, and its erection has been started. This will be an auxiliary plant, the power from which will be used primarily for the construction of the large plant at Thompson Falls. Thirty-three men are now employed on the Prospect creek work, and the plant should be in operation early this fall. The Iron Mountain mine, at Superior, expects to receive power from the new plant, but the main Coeur d'Alene district will not be benefited until the large Thompson Falls plant is at work.

Thompson, August 23.

#### SILVERBOW COUNTY

B. B. Thayer, president of the Anaconda Copper Co., has completed his semi-annual inspection of the company's properties in Montana. "The improvements we have been making the past year or two are rounding into shape," he said. "Several of the large hoisting engines are being operated by air compressed by electric power, and are working satisfactorily. It is the intention of the company to equip all of the larger shafts and many of the smaller ones with compressed-air engines. The electric pumps supplanting the steam pumps formerly in use are now in operation at many points and are giving perfect satisfaction. The mines generally are in fine condition and are making a normal output of ore, with the exception that for the month of August and a portion of September the shipments to the Anaconda smelter will be slightly curtailed owing to the fact that the reconstruction of the first section of the Washoe concentrator is under way."

### NEVADA

#### ESMERALDA COUNTY

(Special Correspondence.)—Operations at the Pittsburg-Silver Peak mine and mill are in the usual condition. Ex-

tensions to slime presses have been completed, making three 86-frame presses. For regrinding the coarsest sand, a 5 by 18-ft. chain-driven tube-mill is at work, being fed by an Akins classifier. Additional plates have been fitted for amalgamation after regrinding.

Blair, August 28.

The shaft of the Goldfield Merger mine is down 1300 ft. That of the Grizzly Bear claim of the Goldfield Consolidated has been enlarged and retimbered from the 1000 to the 1300-ft. level, and is being sunk to 1450 ft. Rich ore is being extracted from the 1300-ft. level. Good ore is being mined on the 250-ft. level of the Florence Goldfield.

#### LYON COUNTY

The Thompson smelter received 4856 tons of ore for the week ended August 22, and shipped away eight carloads of copper matte.

#### NYE COUNTY

(Special Correspondence.)—A project is being promoted to supply Tonopah and Goldfield mines with cheap power by producing commercial coke from the coal beds at Coal-dale, a station on the Tonopah & Goldfield railroad, 35 miles from Tonopah. It is stated that large deposits of coal have been proved and the product can be converted into coke at low cost. The project includes the establishing of electric generating stations, steam to be generated from coke, and supplying electrical power to the mines and mills. It is also planned to furnish coke and gas for domestic and manufacturing purposes to nearby towns. N. S. Cutter, president of the Tonopah & Goldfield railroad, is said to be interested. It is reported that the coal beds will be shortly sold outright to the new company by P. V. Rovlanenk, the owner. The steady rise in the price of silver has added about \$30,000 per month to the value of Tonopah's output since August 1. Tonopah ores average about two-thirds silver and one-third gold in net values, and the gold content practically covers all costs, leaving the silver as a net profit. The steady advance of the white metal has not only encouraged operating companies, but has materially stimulated prospecting and development work on the smaller properties. The Nevada-California Power Co. reports the closing of new contracts amounting to \$101,900 in the past 30 days for Tonopah mines. The additional power is divided among 21 companies. The new Belmont mill is at last in full operation. Failure of the Tonopah Water Co. to furnish sufficient water for the batteries handicapped initial runs. The company has augmented its supply, and the Belmont people are also pumping water from the mine, and no further trouble from this source is anticipated. While in most camps water in the mine is considered detrimental, in Tonopah its presence is being converted into an asset.

Tonopah, August 26.

At the Manhattan Big Four mine, a raise from the 500-ft. level is in \$15 ore. A lode of white quartz 30 ft. wide, worth \$60 per ton, has been cross-cut on this level. The triple pump is being fitted together. A 150-ton mill has been ordered from the Joshua Hendy company. It will contain ten 1050-lb. stamps crushing through 4-mesh screens, two tube-mills, amalgamating plates, and other plant. Tonopah mines shipped 10,000 tons of ore during the last week of August, worth \$250,000. At the 850-ft. level, 6 ft. of ore ranging from \$19 to \$37 per ton has been opened in the North Star mine. At the Montana-Tonopah 5 ft. of good ore has been cut on the 390-ft. level; also 5 ft. on the 565-ft.; and 4 ft. on the 765-ft. level. The West End company has purchased the Salsberry and Crocker claims, 600 ft. south of the West End lease. An initial shipment of bullion was made by the Belmont new mill, valued at \$27,000.

#### STOREY COUNTY

During the week ended August 31, the Mexican mill treated 110 tons of ore worth \$19.80 per ton, with an extraction of 92%. The plant was shut down for several days for repairs to agitators, pumps, Chilean and tube-mills, and

filters. The southwest drive on the 2500-ft. level of the Ophir is out 499 ft. in quartz and porphyry of low value. Work at the cyanide plant is well forward. • At the C. & C. shaft, 24 shifts were worked on the temporary pump plant. Sundry repairs were made from the 800 to the 2100-ft. stations in Ward shaft.

Bullion tax statements filed for the quarter ended June 30, for the Comstock mines, show that 21,356 tons of ore was treated for bullion worth \$269,616. The tax to be paid amounts to \$2178.

### TEXAS

#### BREWSTER COUNTY

(Special Correspondence.)—The Texas Mica Co. has acquired 800 acres of mica land which it is developing. This is situated along the dividing line of Culberson and El Paso counties, southwest of Van Horn. It is stated that unlimited quantities of sheet and scrap mica have been found. The product is ground into 100-lb. sacks and shipped from Van Horn in carload lots, being sold for \$35 per ton at Van Horn. A company of Austin, Texas, men is developing a vein or dike of disseminated tungsten ore situated on the east side of the Diablo mountains. The ore in seams is high-grade, but at present has not been found in commercial quantities. A force of 15 men is employed.

The properties of the Silver Hill Mining & Milling Co. at Shafter, Texas, are at present being worked under lease and bond by the General Development Co. of New York, controlled by the Lewisohns. These mines adjoin the famous property of the Presidio Mining Co. The Lewisohn concern has been drilling with churn-drills to cut the formation at 400-ft. depth. T. H. Clark is the local agent, and Louis A. Wright consulting engineer.

The Consolidated Kansas City Smelting & Refining Co. is erecting an additional converter and new blowing engine to its large copper smelters at El Paso. In view of the increasing production of New Mexico and western Texas, the company has found it necessary to increase its capacity. An extension is also being made to the power-house. These improvements will increase its daily capacity by about 500 tons. K. Doer has been made general manager of the company's interests in the southwest.

Austin, September 1.

#### EL PASO COUNTY

At the Hazel mine, ten miles north of Allamore, a 100-ton dry concentrating mill of the Steele-Sutton-Steele type is being erected. The building is to be three stories high, of wood, steel, and concrete, 65 by 155 ft. The engines are 55 and 85 hp., respectively, and the crusher and pulverizer have a capacity of 200 tons per day. Tests by this process show that 10 tons can be concentrated into one ton valued at \$150. On old dumps there is over 50,000 tons of ore which will average \$15 per ton in copper and silver.

#### WOOD COUNTY

The Bonanza mine, in the Quitman mountains, thirty-five miles by rail southeast of El Paso, has recently been purchased from the Republic company of Weatherford. There are 30 men at work, and regular shipments of sphalerite averaging 44% zinc, are being made to the Granby smelters at Neodosha, Kansas. The property has been opened to 300-ft. depth. The ore also carries galena, which is hand-sorted from the zinc ore and sent to El Paso smelter.

### CANADA

#### BRITISH COLUMBIA

In the Nelson division the Motherlode Sheep Creek Mining Co. is operating its 10-stamp mill, crushing ore from No. 1 vein, and it has been reported that No. 2 and 3 veins have been cut on the 300-ft. level. The Queen gold mine, with its 20-stamp mill, and the Emerald lead mine are two other properties in this part of Nelson mining division that are steadily maintaining production. Near the city of Nelson, the Kootenay Gold Mines, Ltd., with a 20-stamp mill, continues to take out and crush ore from its Granite-Poorman mines. At Rossland the Consolidated

Mining & Smelting Co. is keeping up the output from its Centre Star-Le Roi group, shipments for the half-year having totaled rather more than 100,000 tons of gold-copper ore. Le Roi No. 2 is also shipping its usual quantity of ore. In the Boundary district the Granby company's production for the past six months has exceeded 600,000 tons, while that of the British Columbia Copper Co. has been approximately half that amount. The latter company is exploring Voigt's group of mineral claims, in Similkameen district, but the ore developed is not yet enough to insure the bond being taken up. The Hedley Gold Mining Co. is doing well, as usual; its dividends for the half-year have totaled \$120,000, which is 10% on the issued capital.

#### COBALT

During the week ended August 24, twelve mines shipped 391 tons of ore. The Penn-Canadian sent out nearly 30 tons; while the Crown Reserve shipped one carload containing 135,000 oz. of silver to the Saxon Government, under its contract with that country, to supply silver for coinage. Silver bars weighing 77,424 oz. were produced by the Nipissing and Crown Reserve mines.

A large party of men interested in the Cobalt Townsite mine has visited the property, and considered everything to be satisfactory. Besides its shipments of high-grade ore, the company is having 150 tons per day milled at the Northern Customs concentrator, 20 additional stamps having been erected to deal with this ore.

#### PORCUPINE

A plant consisting of 10 stamps, two tube-mills, and amalgamating plates is to be erected at the Dome Lake mine. Concentration and cyaniding will be used later if necessary. Underground development continues to show encouraging results. At the 300-ft. level of the McIntyre mine the lode has been opened for a good width, the quartz veins carrying fine pyrite. Extensions to the existing mill will consist of rolls and Chilean mills, tube-mills, Colbath classifiers, thickeners, agitators, and filters. Cyanide solution will be added to the Chilean mills.

#### MEXICO

##### CHIHUAHUA

(Special Correspondence.)—At Chihuahua, the American Smelting & Refining Co. is working full time; while the Rio Tinto, at Terrazas, has just blown in one furnace, and expects to blow in another soon. The Santa Eulalia mines, of the Chihuahua Mining Co., are shipping to full capacity. The Yoquiva Development Co., above Minaca, has managed to keep its cyanide plant working, and recently made a shipment of bullion to Chihuahua. They have been harassed by rebels under command of Captain Salazar, while his superior officer, Colonel Gamboa, has occupied the Ocampo region. All the mines at this place are closed down except the Concheño, at which property a new steam electric-power plant is being erected. The Zaragosa shaft is being retimbered and mill repairs made preparatory to starting again.

Temósachie, August 21.

##### GUERRERO

(Special Correspondence.)—The present condition of affairs in the states of Guerrero and Morelos is dangerous. Recently a mechanic of the Alixtex Mining Co., in the former state, was held up and robbed by bandits within two hours' horseback ride of the mines.

Mexico City, August 28.

##### JALISCO

The Mololoa and El Favor mines, in the Hostotipaquillo district, continue to maintain production, and development is opening new stopes. During July, 36 tons of high-grade ore was shipped from the former to the Aguascalientes smelter, while 523 tons was treated at El Favor mill. From 298 tons of El Favor ore sent to the same smelter, the estimated value is \$40,000. A profit of \$4000 was made on treating 417 tons of manganiferous ore in the El Favor mill.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

F. M. SIMONDS is in Cuba.

H. RIES is in San Francisco.

F. L. SIZER is at Carson City.

H. C. HOOVER is in San Francisco.

W. R. CALVERT has gone to Alaska.

CHARLES JANIN is back from Nevada.

H. W. TURNER is in San Francisco again.

EDMUND JUESSEN has returned from Nogales.

CHARLES W. MORSE is at Jackson, California.

E. H. NUTTER has returned from British Columbia.

W. J. SHARWOOD has been called to Washington, D. C.

JOHN SEWARD is examining the Kerr Lake mine at Cobalt.

J. F. KEMP, who has been at Panama, is in New York again.

C. C. BROADWATER has returned from the East and British Columbia.

R. P. McLAUGHLIN has returned from Shasta county, California.

A. F. FLYNT, of Tepic, Mexico, is in San Francisco and will go to Duluth.

R. W. PACK is studying the California oilfields for the U. S. Geological Survey.

W. H. ALDRIDGE may hereafter be addressed at 14 Wall street, Bankers Trust building, New York.

H. M. CROOKSHANKS has resigned as general manager for the Atlitex Mining Co., Guerrero, Mexico.

J. W. MALCOLMSON is expected at El Tigre, Sonora, and will go from there to Los Angeles and San Francisco.

A. W. COLE is now mill superintendent for the Choncheño Mining Co., at Temósachie, Chihuahua, Mexico.

R. B. HUTCHINSON has resigned as general manager for Corrigan, McKinney & Co. in Mexico, and is motoring through California.

NORVAL J. WELSH is at Orogrande, New Mexico, planning development of the By-Chance mines for the Jarilla Copper Syndicate, Limited.

SPENCER BROWNE has gone to New York by way of British Columbia. He will hereafter be with the Canadian Mining & Exploration Company.

P. JENSEN, general manager at the Simau Mines at Lebong Tandai, West Sumatra, is at San Francisco, and will visit various American gold mines.

WILLIAM J. PRIESTLY, JR., has resigned the position of superintendent at the Rhodes-Hall mine, Fairbanks, Alaska, and has gone to Brigham City, Utah.

## Obituary

W J McGEE, whose serious illness was noted in a recent number of the *Mining and Scientific Press*, died at Washington, D. C., September 3, as a result of cancer. Mr. McGee was born at Dubuque, Iowa, in 1853 and read geology while working as clerk in a lumber yard. He used his vacations for travel on foot over eastern Iowa, studying the Pleistocene formations, and became one of the pioneers in the study of glacial deposits. In 1883 he became a member of the U. S. Geological Survey, where he rose to the position of principal assistant to J. W. Powell, then director. He later served in the Bureau of Ethnology, and as director of the Anthropological exhibit at the Louisiana Purchase Exposition. He was one of the active men in the organization of the conservation movement, and at the time of his death was in the service of the Department of Agriculture. Mr. McGee was a forceful man with much originality and power. He was simple and kindly in his tastes, and many a young worker in science remembers gratefully encouragement and stimulus received from him at times when they were most helpful.

### LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco September 5.

Antimony	11-11 1/2c	Quicksilver (flask)	42.50
Electrolytic Copper	18-18 1/2c	Tin	50-51 1/2c
Pig Lead	6.10-6.05c	Spelter	8-8 1/2c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, September 4.—Copper is quiet and firm. Consumption is excellent. Early deliveries are scarce. Lead is strong and advancing. There is good demand at higher prices. Spelter is quiet but firm. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Aug. 29	17.59	4.65	7.17	61 1/2
" 30	17.58	4.85	7.23	62 1/2
" 31	17.58	4.85	7.23	63 1/2
Sept. 1	Sunday.	No market.		
" 2	Holiday.	No market.		
" 3	17.55	4.85	7.29	—
" 4	17.55	4.85	7.29	62 1/2

### SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	53.81	56.25	July	52.57	60.67
Feb.	52.23	59.06	Aug.	52.17	61.32
Mch.	52.76	58.37	Sept.	52.43	...
Apr.	52.32	59.20	Oct.	53.37	...
May	53.31	60.88	Nov.	55.77	...
June	53.04	61.29	Dec.	54.85	...

### COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.29	14.09	July	12.47	17.19
Feb.	12.26	14.08	Aug.	12.41	17.49
Mch.	12.14	14.68	Sept.	12.20	...
Apr.	12.02	15.74	Oct.	12.19	...
May	11.99	16.03	Nov.	12.61	...
June	12.39	17.23	Dec.	13.55	...

### COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1910	141,766,111	244,961,280
January 1911	122,030,195	230,264,280
December "	111,785,183	164,151,680
January 1912	89,454,695	178,329,920
February "	66,280,643	153,820,800
March "	62,939,988	141,125,680
April "	62,367,557	137,806,000
May "	65,295,368	134,176,000
June "	49,615,643	117,801,600
July "	44,335,004	107,817,920
August "	50,281,280	113,285,760

### UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
July	112,167,934	56,982,582	74,880,658
August	125,493,667	59,935,364	69,885,660
September	115,588,950	57,311,584	50,824,011
October	118,255,442	64,068,656	60,084,349
November	111,876,601	68,039,776	67,049,279
December	122,896,697	65,988,474	79,238,716
Total for 1911	1,431,938,338	709,611,945	754,932,733
January 1912	119,337,753	62,343,901	80,167,904
February	116,035,809	56,228,368	63,148,096
March	125,694,601	67,847,556	58,779,566
April	125,694,001	69,513,946	53,252,326
May	126,737,836	72,702,237	69,485,945
June	122,315,240	66,146,229	61,449,650
July	137,161,920	71,093,120	60,121,600

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan. ....	4.48	4.43	July .....	4.50	4.71
Feb. ....	4.44	4.03	Aug. ....	4.50	4.54
Mch. ....	4.39	4.07	Sept. ....	4.48	....
Apr. ....	4.41	4.20	Oct. ....	4.27	....
May ....	4.37	4.20	Nov. ....	4.30	....
June ....	4.34	4.40	Dec. ....	4.45	....

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan. ....	5.45	6.42	July .....	5.70	7.12
Feb. ....	5.52	6.50	Aug. ....	5.95	6.96
Mch. ....	5.56	6.57	Sept. ....	5.86	....
Apr. ....	5.40	6.63	Oct. ....	6.10	....
May ....	5.35	6.68	Nov. ....	6.38	....
June ....	5.50	6.88	Dec. ....	6.30	....

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan. ....	44.60	43.75	July .....	48.00	43.00
Feb. ....	48.40	46.00	Aug. ....	50.00	42.50
Mch. ....	52.50	46.00	Sept. ....	47.50	....
Apr. ....	50.90	42.25	Oct. ....	46.12	....
May ....	46.50	41.75	Nov. ....	45.50	....
June ....	46.50	41.30	Dec. ....	44.50	....

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	41.25	42.53	July .....	42.40	44.25
Feb. ....	41.61	42.96	Aug. ....	43.32	45.80
Mch. ....	40.16	42.58	Sept. ....	39.75	....
Apr. ....	42.18	43.92	Oct. ....	41.18	....
May ....	43.11	46.05	Nov. ....	43.12	....
June ....	44.61	45.76	Dec. ....	44.65	....

Current Prices For Chemicals

(Corrected monthly by Braun-Knecht-Helmann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

## James Lewis & Son's Copper Report

During July, standard copper prices have been subject to market attacks, followed by the absorption of large quantities by leading dealers, and considerable covering of previous sales by operators. The result at the end of the month is a rise of 15s. per ton for cash, three months' prompt being unaltered.

From £77 6s. 3d. for cash on July 1, standard fell to £71 13s. 9d. on July 9; but rapidly recovered next day to £75 10s., on receipt of favorable American statistics. It again declined to £72 12s. 6d., and advanced steadily to £79 5s. on July 23, with a backwardation of 2s. 6d. per ton for three months. Prices have since dropped to £77 8s. 9d. for cash, and £77 11s. 3d. for three months prompt; but recovered to £78 12s. 6d. cash on August 1. English warrants available amount to only 27,200 tons, of which 1200 tons is in the form of wire bars and ingots.

European demand for refined copper has been but moderate, manufacturers' requirements being supplied from previous purchases, with a disinclination on their part to carry more stock than is absolutely necessary. A large demand was, however, experienced from American consumers last week, who are reported to have purchased over 10,000 tons of electrolytic copper at 17½c., leading producers being well sold for October and November delivery. Good orders for English manufactured copper have been booked, and the electrical industry continues very active, both in Europe and the United States, early delivery being unobtainable. There is every prospect of consumption of copper continuing to be very large for many months to come.

The consumption of foreign copper in Germany for the half-year is returned as 109,727 tons.

American shipments from northern ports for July are given as 26,561 tons. The total imports into England and France for the month have been 19,034 tons, and deliveries 17,056 tons fine copper. Chilean copper amounting to 1115 tons has arrived in England, and deliveries 858 tons; while from other countries the totals were 10,027 and 10,297 tons respectively. Liverpool and Swansea received from the United States 2290 tons of bars, 1058 of plate, and 11 of matte, equal to about 3336 tons of fine copper. In London 175 tons was received, and in France 6020 tons. The Chilean charters for the month are advised at 4000 tons, including 1675 tons for the United States. Exports from the former country to July 31 were 21,060 tons, against 18,749 for the same period of 1911.

## Metal Mining in Oregon

The value of the mine production of gold, silver, and copper in Oregon in 1911, according to Charles G. Yale, of the U. S. Geological Survey, was \$669,016, against \$700,676 in 1910. No output of lead or zinc was reported in either 1910 or 1911. The ore (and 'tailing') treated in 1911 was 94,353 short tons, against 82,132 short tons in 1910. The tailing treated in 1911 amounted to 44,246 tons, against 12,142 tons in 1910, so that the increased total tonnage treated in 1911 was not due to a larger production of crude ore. The production of gold decreased from \$679,488 in 1910 to \$633,407 in 1911. Gold output from deep mines decreased \$43,430, and that from placer mines decreased \$2651, compared with the output of 1910.

The production of silver increased from 39,978 fine ounces, valued at \$19,428, in 1910, to 45,221 oz., valued at \$23,967, in 1911. Of the silver, 34,011 fine ounces was derived from silicious ores, 9953 oz. from copper ores, and the rest from placer mines. The copper ore shipped to smelters amounted to 4205 tons, having a copper content of 93,136 lb., valued at \$11,642. This indicates an average recovery of 22.2 lb. of copper per ton. The average recovery of gold and silver from copper ores was \$3.32 per ton.

Baker county led in gold production, with an output of \$389,786, of which \$372,405 was derived from 74,558 tons of silicious ore and from tailing. Josephine county produced \$99,363 in gold, of which \$86,557 came from placer mines. Of the silver production of 45,221 oz., over two-thirds came from Baker county. Copper ores yielded the greater part of the 10,436 oz. of silver credited to Josephine county, which also produced about 90% of the 1911 output of copper in Oregon.

The combined output of gold from southwestern Oregon in 1911 was \$188,971, of which \$123,008 was placer gold. The placer gold production of this region decreased \$7095 and the deep-mine output decreased \$13,258. The mines of northeastern Oregon produced \$444,436 in gold in 1911, of which the placer yield was \$45,266 and the deep-mine yield \$399,170. The placers of this region showed an increase of \$4444 and the deep mines a decrease of \$30,172.

There were 40 deep mines and 136 placer mines operated in Oregon in 1911. Of the placer mines, 88 were hydraulic, 3 dredging, 9 drifting, and 36 sluicing properties.

PRIVATE PROPERTY in mining lands in Brazil is recognized, but ownership implies certain responsibilities. To the proprietor of lands beneath which mineral deposits are known to exist is secured the first right of exploration. Already known deposits may be registered by their proprietor, whereupon he is granted three years' exemption from taxation in which to begin work; at the end of this term a small tax is levied on the declared or estimated value of the property, which may be expropriated if not being worked. Licensed prospectors may prospect on public or private grounds, and discoveries made on the latter entitle the prospector to expropriate the estate for its surface value as declared by arbitration. Discoveries on public land entitle the discoverer to a grant of the land, with a reasonable period wherein to commence active work.

The number of productive mines in New Mexico in 1911 was 105, of which 20 were placers, as against 108 in 1910, of which 23 were placers. The average total recoverable value per ton of ore produced decreased from \$13.89 in 1910 to \$11.54 in 1911. There were 232,699 short tons of ore from New Mexico sold or treated in 1911, an increase over the output of 1910 of 40,834 tons. Of this total, 109,113 tons went to amalgamating and cyaniding mills, 59,622 tons to mills for concentrating only, and 63,964 tons went crude to smelters. Of the \$452,592 in gold and 771,014 oz. of silver in bullion produced in New Mexico in 1911, the cyanide process yielded \$370,472 in gold and 769,608 ounces of silver, the remainder being recovered by amalgamation.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**QUICKSILVER** to the extent of 35.12% was lost at the Alaska Treadwell mills last year.

**USE** of petroleum for fuel at numerous *oficinas* in the nitrate field has upset the balance of traffic between Europe and South America. Steamers that formerly took coal from England and Australia to the West Coast and to carry nitrate on the return trip, are now at a loss for out-bound traffic.

**CONCENTRATE** may be fed into an Edwards furnace by means of small screw conveyors working in a cast iron tube or barrel, bolted to the feed-end of the furnace. They may also be fed in by means of a slow-running belt about 14 in. wide, which drops them into a small hole in the top of the furnace at the feed-end. The belt may be fed from a storage bin by a screw or push conveyor.

**QUEENSLAND'S** gold yield for June was valued at \$590,000, a decrease of \$132,000, compared with the same month of 1911. This falling off was due to decreases mainly from Charters Towers and Gympie. For the first half of the current year the output was valued at \$3,618,000, a decrease of \$303,000 on last year. Dividends paid in June totaled \$288,500, of which Mt. Morgan paid \$240,000. The annual report of the mines department gives the charges for crushing ores at different mining districts in Queensland, the following being at the better known centres: Charters Towers, \$2.64 per ton; Chillagoe, \$2.88; Croyden, \$2.40; Etheridge, \$3; Gympie, \$1.68; Mt. Morgan, \$3.60; and Palmer, \$4.80 to \$6 per ton.

**PLATINUM**, according to the U. S. Geological Survey, was produced only in California and Oregon among the United States in 1911. The total output was 628 oz., valued at \$18,138, compared with 390 oz., valued at \$9507, in 1910. Importations of crude platinum sand in 1911, resulted in an estimated refined product of 27,500 oz. An additional amount was derived from imported ore and matte, so that the total refined platinum produced in domestic refineries was 29,140 fine ounces. The platinum imports for consumption in the United States in 1911 were valued at \$4,866,207, an increase of \$1,212,543 over those of 1910. Exports amounted to \$8139. The world's production of the metal in 1911 was 314,323 oz., compared with 286,952 oz. in 1910.

**DURING** the year ended December 31, 1911, the Han-Yeh-P'ing Iron & Coal Co., Ltd., produced 93,337 tons of pig iron and 24,216 tons of rails. Of the former, 4465 tons was exported to the United States, 5765 tons to Australia, and 58,535 tons to Japan. From the company's Tayeh iron mines 359,467 tons of ore was produced, of which 110,500 tons was exported to foreign ports during 1911. Owing to the revolution in China, the iron and steel works at Hanyang have been shut down since last October, but work will soon be resumed, the furnaces not having been so seriously injured as was expected by their being abandoned while charged. The iron mines were worked right through the fighting. All the foreign experts formerly employed have been discharged.

**ROASTING** a concentrate containing 20 to 30% sulphur in an Edwards furnace, an important factor in successful results is the free access of air on the hearth, and keeping the temperature of the feed end of the furnace as low as possible. It was found at the Horse Shoe mine that minute particles of concentrate became oxidized on the exterior, while the interior was practically unroasted. To remedy this defect, all the side ports were left open except

the last four on the finishing hearth, with the result that a greater roasting capacity per furnace, and a sweeter roast were attained. Additional air is also admitted to the furnaces by having all the rabble spindles, not water-cooled, hollow, so that a strong current of air is drawn down through each spindle, and on the concentrate being roasted.

**DRY CLEANING** of coal has been adopted in Franklin county, Illinois, and a process adapted from the anthracite region of Pennsylvania is in use. The coal is first carefully sized on a series of gyratory screens, and then by a spiral separator which makes three products: coal, bone coal, and 'slate.' The spiral separator consists of a centre column, with a series of spiral bands, down which the coal and slate slide. The coal maintains a fixed path as long as the friction of the coal on the chute and the centrifugal force balance. As the velocity increases, to where it overcomes the friction, the coal moves over the outer edge of the spiral plate and is carried off through a hopper. The slate, with a higher coefficient of friction, follows the regular path down the spiral and at the bottom goes into the refuse pocket. The bone coal takes a path between the two and slides to the outer edge of the spiral, but does not follow the coal over the edge. It is delivered at the bottom through a special gate, and may then be conveyed to the boiler house.

**GAS-ENGINES** of many makes are used to a large extent in Western Australia for driving mills, generators, and all types of industrial machinery, with generally satisfactory results. In the issue of the *Mining and Scientific Press* of August 3, in a paper on the Yuanmi mill, mention was made of the Crossley gas-engine driving 20 stamps, tube-mill, and slime plant. In the June issue of the *Chamber of Mines Journal*, W. R. Degenhardt gives full details of a test of this engine, the following being a few of the more important data obtained:

Horse-power at sea-level.....	200
Cylinder, inches .....	24 by 32
Speed, revolutions per minute.....	166
Hours run for month.....	734
Brake-horse-power (average) .....	147
Explosions per minute .....	83
Pounds of charcoal used per hour.....	147
Pounds of charcoal used per hp-hr.....	1
Cost per ton of charcoal delivered at generator....	\$14.16
Cost of charcoal per hp-hr., cents.....	0.63
Gallons of condensed water used.....	16.165
Gallons of lubricating oil used.....	147
Total costs per hp-hr., cents.....	1.38

**STOPING** by the 'rill' system it becomes necessary, in handling the broken rock, to make connections between levels by raising and winzing about every 100 or 150 ft. along the orebody. After the leading stope is taken off for the full length of a drift, the level is timbered. Single stulls up to 14-ft. width are put in. If the span is too great for stulls, set timbers or saddleback stulls are used. Stulls are lagged over with slabs or 4-in. poles, and wooden chutes are built at intervals of 50 feet. Ore passes are cribbed up through the filling directly above each chute, and are built of 7-in. round or 3 by 9-in. square timber, the passes measuring 4 by 4 ft. in the clear. Occasionally a double pass may be carried up, one side serving as a traveling way. Stoping is commenced off the winzes, and rills are gradually formed, one on either end of each winze. The rills are generally at an angle of 37° off the horizontal, this allowing for the boring of all water-holes. After the rill is cut through, and the ore, which gravitates down the rill to an ore-pass, is cleaned up, machines are shifted to another position of the stope, ore-passes built, and the stope filled. The filling, generally consisting of residue, is dumped down the winzes from the level above, and gravitates down the rill into position, although at the extreme points of rills, a certain amount of handling is required.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### CONFLICTING LOCATIONS

The location or extension of a mining claim upon ground within the marked boundaries of another valid and subsisting location is absolutely void for the purpose of founding a contradictory right, and it is immaterial that the overlapping locator was the first to make a discovery either within or without the overlapping area.

Becker v. Long (Alaska), 196 Federal, 721. June 4, 1912.

### CLAY NOT A 'VALUABLE' MINERAL

The Land Department is of the opinion, from an examination of standard authorities on cement materials and manufacture, that clay suitable for use in the manufacture of portland cement is so widely distributed that its value in a natural state in place constitutes such a small element of the cost of the manufactured product, and that its practical availability as a cement ingredient is so largely dependent upon the existence of certain extremely favorable artificial or natural conditions, it cannot properly be regarded in and of itself as a valuable mineral deposit within the meaning of the mining laws, and hence is not subject to location as a placer claim.

Bettancourt v. Fitzgerald (Land Department), 40 Land Decisions, 620. January 29, 1912.

### EXTRACTION OF MINERALS TO DETRIMENT OF SURFACE

A land-owner conveyed a certain tract to the plaintiff in this case, reserving all minerals under the surface. Subsequently the owner conveyed to the defendant all subsurface mineral rights, but in extracting the shale, which was the mineral in question, defendant greatly damaged and injured the surface of the ground. In a suit to enjoin further mining operations it was held: (1) that shale was a mineral within the meaning of the reservation clause in the deed, (2) that defendant acquired by the grant of mineral rights the right to sink shafts, slopes, drifts, or to make openings of a character reasonably necessary and convenient for mining operations, but where the stratum of mineral lies so close to the surface that it cannot be mined without destroying the surface in its natural state, the mineral so located cannot be mined.

Bibby v. Bunch (Alabama), 58 Southern, 916. June 4, 1912.

### MINING LAWS APPLICABLE TO ALASKA AMENDED

By an Act of Congress, approved August 1, 1912, the mining laws applicable to Alaska have been amended as follows:

1. No association placer-mining claim shall hereafter be located in Alaska in excess of 40 acres, and \$100 assessment work shall be done each year and until patent for each and every 20 acres or excess fraction thereof.

2. No person shall locate any placer claim in Alaska as attorney for another unless he has a duly acknowledged power of attorney on record in the recorder's office of the judicial division where the location is made. Any person so authorized may locate placer claims for not to exceed two other persons under his power of attorney for them, and not to exceed two placer claims for each of said principals during any calendar month.

3. No person may locate or cause or procure to be located for himself more than two placer claims in any calendar month, provided that one or both of such locations may be included in an association claim.

4. No placer-mining claim hereafter located in Alaska shall contain a greater area than is fixed by law nor which is longer than three times its greatest width.

5. Any placer attempted to be located in violation of this Act shall be null and void, and the whole area thereof open to location as if no such prior attempt had been made.

Act of Congress, approved August 1. (Not yet published.)

## EDITORIAL

WHY has not the Chinese Republic been recognized by the United States? Is this more of the "dollar diplomacy"?

CANANEA seems safe from the rebels for the present, as the Federal troops have been reinforced. Mexican troops have been allowed to cross United States territory, and it will be but an easy step from that, if need be, to allow United States troops to follow raiders across the border.

CAREFUL investigations of the coal and transportation problems of Alaska are under way. The new Alaska Railroad Commission has already sailed for Seward and a party of engineers from the Bureau of Mines is about to start for Katalla. Delay in passing the appropriation bills at Washington precludes much work being done this season, but, with large parties, something at least may be accomplished.

SEASONS are short at Nome, and work must move fast through the summer months. The first boat in and the last boat out are always crowded. Usually the last boat comes down late in October, after which communication is only by dog train to Fairbanks, and so out to the coast. By error we announced in our news columns last week that the last boat had already left for Nome. The well known *Senator* will, however, go up as late as October 7.

FROM a report made by an 'engineer,' the following sentences are culled: "The vein occupies a fissure of large extent horizontally and perpendicularly along the axes of an incline, with a strike north and south standing perpendicularly." \* \* \* "Working of this mine consists of approximately 8000 feet and a shaft 600 feet deep, originally operated as a tunnel to a depth of about 400 feet." Interesting food for reflection may be found in determining whether an incline "standing perpendicularly" is a greater natural wonder than a tunnel which has been plunged into the earth to serve as a shaft.

OUR circle of special correspondents has again been broken, this time by the death of T. Lane Carter, at Dillon, Montana. Our readers have received much both of pleasure and information from his writings, and join us, we are sure, in extending sympathy to Mrs. Carter. The affair is all the more tragic in that Mr. Carter's death occurred while they were on their wedding journey, in which business and pleasure had been combined. While details are still lacking, Mr. Carter is known to have lost his life while examining the Polaris mine. He was one of the young American engineers who first made a name for himself in foreign lands, and he was one who cultivated not only the art of doing things, but that of describing them as well. His work carried him to the queer places of Africa, Central America, and other countries, and he saw clearly the human as well as the technical side of mining engineering. We print elsewhere a brief account of his life.

**A**PPARENTLY Judge W. H. Pope thinks he has solved the old problem of how to eat your cake and still have it; at least he seems to have decided in the Stratton's Independence case that removal of ore from a mine does not cause an irreplaceable loss, and that therefore it is not to be charged to depreciation. The matter came up in connection with the United States excise law regarding income of corporations. Since that law went into effect there has been a fairly startling change in mine book-keeping and lively competition among operators to show their losses. Without having the decision before us, we are unable to say upon what ground Judge Pope directed a verdict against the company, but certainly exhaustion of ore reserve constitutes depreciation, if that word has any meaning. The case has been appealed to a higher court for final decision.

**L**AST week the sixth session of the International Association for Testing Materials assembled at New York. This is one of the most important international engineering societies, one that has pursued a consistent constructive program. Americans will be glad to welcome visiting members of the association. The meeting in New York at the same time as the International Congress of Applied Chemistry assured a good attendance of foreign scientists. Excursions, we understand, have been arranged to Washington, Pittsburg, Buffalo, Niagara, and other points. Incidentally there is to be an international conference of the directors of mining experiment stations at Pittsburg, and the engineers of the United States Bureau of Mines are to have the privilege of submitting their work and program to the disinterested criticism of foreign experts. Experimental work is expensive, and coördinate results only are reliable. Coöperation is therefore especially important in this field.

**T**RAINING miners, as distinguished from mining engineers, has received too little attention. In the old days there was in mining, as in other industries, an established system of apprenticeship. Under the pressure for men, incident to the rapid expansion of mining, the old system has gone and nothing has taken its place. In South Africa there is a chronic shortage of even the most unskilled labor, and the project of substituting in part of the work a smaller number of trained men, offers fascinating possibilities. Attempts in this direction have met with only moderate success, and there is a deep-seated belief that where white men and black men work in the mines, the former will not do any manual labor. This is not true in American mines, and, while the conditions are by no means parallel, the fact affords basis for hope. More efficient workmen are needed in the mines as badly as anywhere, and if the standard of living is to continue to rise, the standard of performance must also go up. Mr. M. W. von Bernewitz reviews elsewhere some of the efforts being made to meet this problem, but the outlook is evidently not particularly encouraging. It ought to be possible to devise a system that would train men to perform well the work before them and at the same time open the way of promotion to those showing especial ability and diligence. In the coal mines of the United States, where the influx of ignorant and untrained men has been especially large, multiplication of petty bosses affords some relief. The opportunity for study unfortunately is afforded almost entirely by correspondence courses conducted by private corporations. The American states, notably liberal in their educational work, have done practically nothing to help men already employed in their industries. In the West an exception must be made in favor of the Virginia City

School of Mines, where Mr. D. T. Smith gives, to a small number, individual practical instruction along lines helpful to miners, millmen, and prospectors. While perhaps an occasional graduate mistakes himself for a mining engineer, as does his fellow-graduate from more pretentious institutions, the main work of the school is good and helpful. If we are to keep pace with our competitors and with our own desire for increased luxury in living, we must frankly face this problem of training somebody to do the work of the world.

**A**NNOUNCEMENT that the Freeport Sulphur Company is about to begin production at Bryan Heights, Texas, attracts renewed attention to the curious domes of the Gulf Coastal Plain, from which gas, oil, sulphur, and salt are being won. Mr. Gilbert D. Harris has described these domes in much detail and has explained them as due to the upward thrust developed by salt crystallizing when deposited by artesian water returning to the surface along the intersections of crevices. The theory, which is substantiated by many detailed facts, is a very pretty explanation, and the whole subject of the domes is one of much interest to economic geologists. Credit for recognition of their economic importance is due Mr. A. F. Lucas, who, it will be recalled, was the moving spirit in pioneer drilling at Spindle Top, near Beaumont. Before others were ready to believe that these insignificant mounds, which rise but a few feet above the surface, had any structural significance, he became convinced that they were genetically related to petroleum. We are glad to know that an ample fortune was the reward of his clear thinking and courage. Mr. Herbert Frasch was another who by courageous work won fortune from these domes at the same time that he enriched his profession through development of the technology of the sulphur industry. Just how the Freeport Sulphur Company and the Union Sulphur Company are to get along remains to be seen, but the whole series of discoveries reinforces the old rule that even most insignificant topographic features may often be studied with profit by geologists and engineers.

**W**ORK of the giant converter at the Great Falls plant of the Anaconda Mining Company continues to be a source of both astonishment and satisfaction. Later results than those given in these columns August 7 show a production of 52.3 tons of copper in a single 'blow,' the total time required being 8.5 minutes per ton of copper, or 6.1 minutes actual blowing time per ton of copper. This is at the rate of over 200 tons of blister copper per day from a single converter. A better conception of this enormous converter may be derived from the statement that it is considerably larger than a good sized room, air is blown into it at the rate of three-fourths ton per minute, and a single charge yields a carload of blister copper. The advantages of the upright, or Great Falls, type of converter have been slow in finding recognition, but it is now being employed for new construction in a number of plants in the Southwest and Mexico. This 20-foot converter further demonstrates that, in addition to first securing a proper coating upon the basic lining, the essential feature of successful operation is temperature control, which is the more easily secured the larger the mass of hot material that is handled. The heat lost by radiation and carried away by escaping gases is of less importance in a large converter, while the opening at the mouth renders it possible to add unlimited quantities of cold material to keep the temperature down. Much of the trouble formerly experienced in the operation of converters was probably due to using too small a mass of material; just as, for example, a tack-hammer would be ineffective in hand-drilling.

**S**MELTING is an industry which exhibits many mutations as the supply of ore available changes in character by the working out of old mines and opening of new ones, or by alterations in composition due to increased depth of working. Transportation facilities are equally potent, and ores may become available through a decreased freight rate, or through a lower smelting rate made possible by increased facilities for securing cheap fuel and supplies at the smelting plant. Interesting examples of this are the changes during the past year at the smelting plants in operation at Tacoma, Washington, and Tooele, Utah. In former years the Tacoma plant smelted a considerable quantity of lead ore, derived from the Coeur d'Alene and from the Northwest generally, as well as copper ore, derived largely from British Columbia. Since the Alaska copper mines have become steady shippers and the mines upon the west coast of British Columbia have increased their output, the copper ore-supply of the Tacoma smelter has so largely increased that the plant is now in course of reconstruction under the direction of Mr. W. H. Howard, and a year from now will become one of the important copper smelting plants of the United States, while the lead ores will be diverted to the Selby plant, on San Francisco bay. The Tooele smelter was first built as a copper smelting plant and only recently have lead furnaces been added. The ore supply for these has proved so plentiful that the lead smelting now seems likely to overshadow the copper. As an example of how short the normal life of a successful plant may sometimes be, the Granby copper smelter may be cited. This plant was built twelve years ago and has been smelting ores from the mines owned by the company at the rate of over one million tons per year. Every mine has a bottom, especially when worked at so rapid a rate, and the known ore reserve is expected to last but five or six years more. Meanwhile the company is erecting a smelter at its recently-purchased Hidden Creek mines, and will take up smelting at Granby bay before the end comes at Grand Forks. Such is the isostasy of industry.

### San Francisco and the International Engineering Congress

Last winter preliminary steps were taken toward the organization of an international engineering congress to assemble at San Francisco in 1915. Representatives of the national societies, selected after conference with the officers of each organization, met and outlined a plan which has already been made public. It was proposed to hold a series of meetings at some convenient time in 1915, at each of which one of the national societies should act as host to foreign organizations of engineers in the same line of work. Local arrangements were to be in charge of a local committee, but invitations were to be extended in each case by one of the national societies. For example, the plan contemplated that the American Institute of Mining Engineers and the Mining and Metallurgical Society of America should meet at San Francisco at the same time or in quick succession and should extend invitations to that meeting to the Canadian Mining Institute, the Mexican Institution of Mining and Metallurgy, the Mining Institute of Japan, the Australian Institute of Mining Engineers, and others. As a preliminary step, engineers resident in California undertook to raise a general guarantee fund of \$10,000, and the Exposition officials offered to furnish a suitable auditorium and meeting rooms. A large part of the guarantee fund has been pledged and plans for the auditorium have been approved. Recent conferences between representatives of the local committee and the conference committee of the

national societies in New York, developed some differences of opinion as to the conduct of the proposed congress. The western representatives, Messrs. W. F. Durand and George W. Dickie, promptly made it clear that the Californians were not insistent upon any particular detailed plan, but were ready to work under any that was likely to produce good results. As finally agreed, the conference committee is to recommend to the societies represented, that the congress be under the control of a general committee of thirty, consisting of the president and secretary and four local members of each of the following five societies: The American Society of Civil Engineers; American Institute of Mining Engineers; American Society of Mechanical Engineers; American Institute of Electrical Engineers; and American Society of Naval Architects and Marine Engineers. It was further proposed that an additional fund of \$30,000 be raised, apportioned as follows: civil engineers, \$9000; electrical engineers, \$9000; mining engineers, \$5000; mechanical engineers, \$5000; naval architects and marine engineers, \$2000. This plan is to be referred to the societies concerned for acceptance, and in the meantime nothing can be done.

It will be noted that not all the national societies are included in this revised plan, and this, we believe, is a mistake. While the older societies may naturally be expected to take the lead, there are several young but vigorous organizations that should be invited to take part. For example, any one cognizant of the relative financial conditions of the American Institute of Mining Engineers and the Mining and Metallurgical Society of America, will at once recognize that the latter is in much the better position to give financial aid to the proposed congress. The money matter is, however, by no means the most important. If the congress is to accomplish all that is expected, the big engineers of the world must be brought together. That involves prompt issuance of invitations, since society programs are usually made several seasons in advance. Furthermore, a well considered program must be laid out and much preliminary work must be done. The best sessions of the International Congress of Geologists have been determined six years in advance, and the most important work, such as the world's conference on iron-ore resources that marked the meeting in Sweden, resulted from two or three years' work of international committees. The Canadians are preparing for next year's meeting a corresponding monograph on the world's fuel resources. What could be more appropriate as a general topic for the meeting of 1915 than the world's gold resources? California, first made known to the rest of the world through the discovery of gold, would be an especially appropriate place for taking stock of the known and suspected reserve still in the crust of the earth. Such questions as to whether the supply of gold may be expected to increase in ratio with the world's trade; whether we must look for increase to discovery of veins or improvement in process; whether 'scientific prospecting' will pay; whether the present land laws hinder or help development; all these are at once of world-wide and of intense local interest. The opportunity afforded by the proposed international gathering for a general survey and summing up of these problems is unique. With proper foresight, through coöperation of the American Institute of Mining Engineers, the Mining and Metallurgical Society, and the Geological Society of America, with the help of the affiliated and the foreign societies, a monumental piece of work may be accomplished. It is necessary, however, to act promptly, and we would respectfully call attention to the fact that at present the whole program is stalled for want of action by the societies having headquarters in New York.

## Gold-Dredging in the Boise Basin of Idaho

By JOHN H. MILES

The history of Idaho practically commences with the discovery of gold in 1862, in what is known as the Boise Basin, an area of some fifteen miles square. As many as twenty thousand people worked in the placer mines in the sixties. In '63 the output was reported as \$5,000,000; in '64, \$10,000,000, the amount being probably greater than these figures, as much was taken out of the district that did not pass through Wells-Fargo hands. Many estimates of the total output to date place it between one hundred and two hundred millions of dollars, and some

on Grimes creek, which used a Pelton wheel at high head. On commencing work it was found that the water-supply was insufficient to develop the necessary power, which fact accounts largely for the intermittent operation of the dredges and for the final cessation of work. The Moline Mining Co., operating a Risdon dredge by steam power, with wood as fuel, dredged near Placerville for five years, averaging eight months per season. By working three 8-hour shifts, 1400 cu. yd. was handled per day. The buckets were of the open-link type and 5-cu. ft. capacity. Operations ceased in the fall of 1911, as the ground became deeper than the dredge could handle.

In the fall of 1908 the Boston Gold Dredging Co., managed and owned largely by the late Charles Souther of Boston, built a 3½-cu. ft., open-connected Risdon dredge two miles below Idaho City. The dredge worked successfully until the fall of 1905, when it sank. It was then considered too old to be worth raising, and was abandoned after having worked over about 38 acres. A dipper dredge was built in 1901 near Idaho City. Although it was remodeled in 1902, in 1903, and again in 1904, it did not prove a success, and was abandoned the same year that the neighboring dredge sank, after handling only 11 acres. Both boats were steam operated, using wood as fuel.

Shortly after this the stock of the company was taken over by F. W. Estabrook, of Boston, who at that time was dredging in the California field. Under new management the ground was carefully re-drilled. Plans were made to secure a better and cheaper power supply, and the spring of 1909 saw the completion of a modern power plant about 22 miles from the dredging field. In July 1909, a 5-cu. ft. Risdon dredge was moved from California to the lower portion of the Idaho City property. This dredge has proved quite successful and is handling at present an average of 68,000 cu. yd. per month. The buckets were formerly of the open-connected type, but have been changed to the close-connected type.

A 15-cu. ft. California type dredge built by the Yuba Construction Co., of Marysville, for the Boston & Idaho Gold Dredging Co., on ground above Idaho City, commenced dredging in May 1911. This dredge

BOW OF DREDGE, WITH LADDER STOPPED FOR OILING.

claim even higher figures. In those early days much fairly good ground at creek level was left because of the expense of working it by hand, and many of these spots were covered by tailing from hillside claims. Later, elevators were used to some extent to work such places. Experience has shown that creek-bottom ground is best worked by dredges.

In the spring of 1898 the Bed Rock Dredging Co., a corporation owning 200 acres of land at Placerville, Idaho, constructed a dredge of the Bucyrus type, open-link, double-lift, with 5-cu. ft. bucket capacity. After a month's work in the second season, the dredge was shut down.

In the same year the Centerville Gold Dredging Co. built a dredge of the same type to work its property above Centerville. This dredge was operated all of the season of 1899, was remodeled in 1900, worked during the season of 1901, two months of 1902, and the season of 1903, when it ceased operations. The Bullion Dredging Co. also built a dredge and operated one season. The power for the operation of these dredges was supplied by a plant

(and also the smaller one) has worked continuously through the winter months, night and day, and except for minor repairs, has been in constant use up to the present time, notwithstanding the fact that at times the thermometer has stood as low as 22° below zero. From October 1911 to April 1912 the average width of the pond in which this dredge has dug was 720 ft., with an average depth of 32½ ft. The maximum run was made in October, when 361,876 cu. yd. was handled. For the past twelve months this dredge has handled an average of 307,628 cu. yd. per month at 80.1% running time. The ground carries a great deal of sand, and it is often necessary to run the top material dry. The company owns 680 acres on Moores creek and Elk creek. Although the lumber for both dredges came from the company's own mills and a material saving was effected, it has proved rather expensive to get other portions of the boats, the average railroad freight on the steel and castings being \$1.65 per hundred pounds, and team freight from the nearest railroad point (Boise, 36 miles distant) varying from ¾ to 1¼ cents per pound.

Power is supplied to the dredges from the company's plant on the south fork of the Payette river, where one of the highest rock-filled timber dams in the country was completed in 1909. Two pairs of Leffel Sampson water-wheels are direct-coupled to two 450-kw. generators that furnish 2-phase current at 500 volts and 30 cycles to the transformers, which step the voltage up by means of 'Scott' connection to 19,050 volts, 3-phase. A peculiarity of the system is that the neutral point of the 3-phase

side of the Scott system is grounded at the station, a special tap being provided on the transformers for this purpose. This arrangement permits the use of all of the 11,000-volt transformers first used by the company, by star-connecting them. A break in a single line wire has allowed the operation of considerable load, two wires and the earth completing the circuit to two transformers out of three. After passing over some 27 miles of line, the current is stepped down to 2200 volts, 3-phase, for use on the dredges, being finally taken aboard through armored cables. Owing to the fact that the new load due to the Yuba dredge would make the total load on the power-plant somewhat more than its kilowatt rating, it was decided that the power factor must be increased to avoid overheating the generators and to help the regulation of the system. Accordingly, the specifications were changed to have the 150-hp. induction motor operating the high-pressure pump replaced by a 275-kw. synchronous motor. Dredge engineers were reluctant to do this, fearing that it would prove too complicated and delicate a piece of apparatus for dredge work. However, the motor has proved entirely satisfactory, and has improved the regulation as expected. With leading current equal to the full capacity of the motor windings, the power factor at the plant varies from 97 to 99% lagging. It is possible to bring this motor to synchronous speed with the

TURNING OFF THE LOWER TUMBLER SHAFT FOR NICKEL STEEL SLEEVES, IN THE FIELD.

pump full and discharge-valve closed, but the method used in priming is to start the pump empty and admit a 5-in. stream from the priming pump to the suction pipe of the 14-in. pump, leaving the discharge-valve fully open.

The altitude at Idaho City is 4200 ft. Owing to the dryness of the climate and the intensity of the summer sun, some trouble is experienced through the rapid deterioration of rubber-insulated cables lying on the sand of the creek bottom, and cable-makers propose to furnish varnished cambric cables with waterproofed covering and outer armor for this service. Winter imposes severe mechanical strains on a cable, owing to the depth of the snow and heavy crust at times. The usual galvanized-wire armor, while necessary to the strength and protection of the cable, greatly increases its weight and adds much to the difficulty of handling it in winter. In general, aside from trouble at times with ice in the ponds in extremely cold weather, dredging in Idaho compares quite favorably with that in California fields.

MINING in Uruguay remains almost stagnant, owing to lack of transportation facilities, scarcity of labor, and insufficient legal protection. New railways under consideration should help the first difficulty. Two American geologists have been engaged to organize a geological survey. The total mineral exports during the first half of 1911 were valued at \$328,786. Boring for coal is under way, while graphite and asphalt are being mined. A cement factory with an annual capacity of 300,000 bbl. has been built at Sayago. The country contains a great variety of minerals in payable quantities.

# Geology and Ore Deposits of Creede, Colorado

By W. H. EMMONS and E. S. LARSEN

\*The Creede mining district is situated in Mineral county, southwestern Colorado, near the eastern border of the elevated region generally known as the San Juan mountains. In the eighties the upper portion of the valley of the Rio Grande was a route of transportation between Wagon Wheel Gap and the flourishing camps near Silverton and Lake City. This route passed very near the present site of Creede and nearer still to Sunnyside, a small camp about two miles west of Creede. Some of the Argonauts, halted on the way long enough to prospect the steep mountain slopes along the valley, and, finding encouraging indications, located several claims. J. C. McKenzie and H. M. Bennett located the Alpha, at Sunnyside, April 24, 1883, and with James A. Wilson pegged out the Bachelor claim, near the present site of Creede, July 1, 1884. Some prospecting was done in the middle eighties, principally at Sunnyside, and futile attempts were made to work the ores in arrastres. There is no record of any new discoveries from 1886 until August 1889, when N. C. Creede, E. R. Naylor, and G. L. Smith located the Holy Moses mine on Campbell mountain. The following summer Mr. Creede located the Ethel, and C. F. Nelson located the Solomon claim. The mining district that was formed was called the King Solomon district; it is east of and nearly contiguous to the Sunnyside district.

When it became generally known that Mr. Creede had sold an interest in the Holy Moses mine to D. H. Moffat, of Denver, prospecting was renewed with great vigor, and in June 1891 several prospectors from Del Norte discovered the Last Chance mine on Bachelor mountain. This was on the Amethyst or 'Big' vein, upon which the Bachelor claim had been located six years before, but the two locations were nearly three-fourths of a mile apart. Soon after the location of the Last Chance, Mr. Creede located the Amethyst claim, which joined it on the north, and within a few months the Amethyst vein was pegged for a distance of nearly two miles along its strike.

The railroad from Wagon Wheel Gap was extended to the district in 1891, and the first train arrived at Creede on December 16 of that year. The district has been producing almost continuously since the advent of the railroad. During some of these years silver was at a low price, but the mining operations were profitable, nevertheless. The production in 1910 was \$1,036,286. The total production cannot be stated accurately, but on the basis of data obtained from several reliable sources, the total production is estimated at \$37,500,000. This includes, in order of their value, silver, lead, gold, and zinc. About half this sum was paid as dividends, notwithstanding the low prices at which the metals were marketed.

## MINING AND TREATMENT OF ORE

The larger part of the ore of Creede was partly or completely oxidized. Such ore is not suitable for mechanical concentration and was shipped without dressing to smelters. The greater part of it went to the plant of the American Smelting & Refining Co. at Pueblo.

In the lower levels of the mines on the north end of the Amethyst vein, especially in the Amethyst and Happy Thought mines, large bodies of sulphides suitable for concentration were found. This ore was dressed in the Humphrey mill at North Creede. The Humphrey and Amethyst mills are of the same general type, the equipment including crushers, rolls, classifiers, jigs, tables, and canvas plants. The zincblende and galena are readily separated, giving clean and satisfactory concentrates, and the pyrite is not so abundant as to reduce the grade of zinc

concentrate greatly. Gold and silver are recovered mainly with the lead concentrate or in the slime. Two smaller mills, the Solomon and the Ridge, are situated on East Willow creek about 1½ miles above North Creede. The ore of the Solomon vein is very soft and is crushed by rolls without preliminary breaking in a jaw crusher. Only the Humphrey and Solomon mills were in operation in the summer of 1911, the Amethyst having been closed early in that year.

Conditions are favorable for cheap mining, as the veins are nearly everywhere of good width and have been subjected to very extensive fracturing and crushing since they were formed, so that much of the work has been done with pick and shovel. One of the largest stopes was milled from the bottom without preliminary blasting or breaking the ore. At present all the stoping is done by hand. Owing to the fractured condition of the rock, the miners find their labors lighter than in many neighboring districts.

The mines on the Amethyst vein and those on the Solomon are served by deep adits. The topography is so rugged that these gain depths of 1000 to 1400 ft. within comparatively short distances. The mines contain large quantities of water, which is drained through the adits and is used for milling. Although several deep shafts have been put down, all the mining is done at present through the adits.

## GEOLOGY

Creede lies within the great Tertiary volcanic area of the San Juan mountains, and, so far as known, no rocks other than the Tertiary volcanics are exposed within a

FIG. 1. GENERALIZED COLUMNAR SECTION OF ROCKS ON RIDGE EAST OF RAT CREEK, NEAR CREEDE, COLORADO.

radius of many miles. All the rocks of the area shown on the map of Creede and vicinity are thought to be included in the Potosi volcanic series, which is the third series of the Tertiary volcanic rocks thus far recognized in the region. The rocks of this area are naturally separable into several divisions, and most of these divisions

\*From a preliminary report in Bull. 503-E, U. S. Geol. Survey.

are separated by erosion surfaces. Each division is generally made up of two or more flows or other subdivisions. Fig. 1 is a generalized columnar section representing the succession of the rocks as seen on the ridge east of Rat creek. This section does not show the quartz latite of McKenzie mountain, which overlies a very irregular surface of the other rocks, nor the lake beds in the Rio Grande valley, nor the rhyolite near the Equity mine. The exact positions in the column of the latter two are not known.

The lavas in general dip gently to the north, but the lake beds south of Creede dip gently to the south. It is not known to what extent these structures are original or to what extent they represent actual tilting of the beds. Complicated block faulting is the most important structural feature of the region.

#### ORE DEPOSITS

The ore deposits are silver-lead fissure veins in rhyolite and fractured zones of silver ore in shattered rhyolite. The total production, except a few thousand dollars, has been obtained from the silver-lead fissure veins. These are strong fault fissures and are extensive both vertically and along the strike. They include the Amethyst, Holy Moses, Solomon, Alpha, Mammoth, and several smaller lodes. All of these strike in the northwest quadrant, and the majority dip west or southwest.

Brecciation and faulting have taken place on a large scale, as is indicated by slickensided surfaces with abundant movement striæ and at some places by a lack of correspondence of the rocks on the two sides of a vein. Some of the veins fill fissures along normal faults, and at some places in the hanging-wall blocks there are subordinate fissures which join the principal faults in depth. Such relations are thought to show that the hanging wall was shattered as it was drawn downward by gravity along the foot-wall.

Some of the veins have been opened by movement since the ore was deposited. The results of such movement in the Amethyst vein are very pronounced. The ore itself is crossed by striated slickensided planes, and locally the vein quartz with associated sulphides forms a friction breccia. The ore minerals include zincblende, auriferous galena, pyrite, chalcopyrite, and their alteration products. The gangue minerals include quartz, much of it amethystine, with chlorite, barite, and fluorite. The several veins show considerable differences mineralogically. Hydrothermal metamorphism is not pronounced a few yards away from the veins, but along the most productive portion of the Amethyst vein considerable alteration has taken place. It is attended by silicification and the development of adularia and some sericite. Ribbon quartz and banded crusts are common, indicating deposition in open spaces. At some places near the veins, however, the intensely altered replaced rhyolite constitutes good ore. For reasons which will be mentioned in a subsequent paper, it is thought that these veins have been deposited by ascending thermal waters. As they cut rocks that are probably of Miocene age, the deposits are Miocene or later. In some of the deposits secondary enrichment is pronounced. The rich secondary ores extend downward to great depths, owing to the high relief of the area and consequent ample head of the solutions and the open character of the veins, all of which facilitate a rapid downward circulation.

The fractured zones of silver ore in shattered rhyolite include the deposits of the Mollie S. and Monte Carlo mines. The fractures and joint planes of the rhyolite are filled with thin veinlets of green chrysoprase and other green copper minerals, and locally contain large amounts of silver. Argentite, cerargyrite, and native silver are plastered on the walls of the thin narrow cracks. Iron sulphides are not abundant. The rhyolite along the veinlets is apparently fresh and glassy and is not greatly affected by hydrothermal metamorphism. Deeper exploration has not exposed any body of sulphide ores, and it is possible that the rich ores of this class are genetically related to the present topographic surface.

#### AMETHYST LODGE

The Amethyst lode is the most important deposit of the Creede district. Its total production is estimated at about \$35,000,000 in silver, lead, gold, and zinc. It is developed for about 9500 ft. along the strike, and for the greater portion of this distance it has been exploited to depths of 1000 to 1400 ft. below the surface. Its strike is in general about N. 22° W. At the north end it strikes nearly north and at the south end it strikes about southeast. It dips southwest at 50 to 65°, or locally at greater angles.

The outcrop of the Amethyst vein is notably inconspicuous. The sheeting and crushing which are everywhere apparent along the lode have probably favored its disintegration, and it does not form a ridge at any place.

None of the outcrops, except the one between the Amethyst and Last Chance shafts, would perhaps be considered particularly promising. At this place only has the ore been worked at the surface, and at most places along the lode the stopes do not extend within 200 ft. of the apex. In view of the persistence and the great regularity of the workable ore in the deeper levels, these relations may reasonably be interpreted as indicating a leaching of the oxidized zone.

The great bonanzas of the Amethyst vein were oxidized or partly oxidized ore. This ore consisted chiefly of lead carbonate with some lead sulphate containing large amounts of silver. The gangue of the ore is quartz and silicified rhyolite stained with iron and manganese oxides. Gold was of subordinate importance in the richer oxidized or partly oxidized ores, although some of this ore contained several hundred ounces of silver to the ton. Some of the silver is present as the chloride, cerargyrite, with which is associated the lead chlorophosphate, pyromorphite. Much native silver was present in the ore mined from the upper levels. It occurred as sheets and stringers in the oxidized ore and as little balls of silver wire nesting in open cavities. A common occurrence is a red jasper with flakes and sheets of the native metal. Some selected specimens of this jasper contain as much as 10% of native silver. In cabinet specimens the sheets of silver exhibit a ribbon-like structure with combs of chalcedonic quartz, and both are intergrown and contemporaneous. Under the microscope the jasper is seen to be made up of quartz and finely divided iron oxide. Native silver and jasper are confined to the oxidized ore and were not noted in the lowest levels of the mines.

#### SULPHIDE ORES

In the lower levels, in general about 500 to 800 ft. below the apex of the vein, sulphides of zinc and lead become increasingly prominent. These are more abundant in ore found at higher elevations in the north end than in the south end of the lode. There is no sharp line of contact between the oxidized and sulphide zone, but along fractures the oxidation extends downward here and there to the adit level. Partly oxidized ore is found in several of the mines 1000 to 1400 ft. below the surface. In the lower levels of the Happy Thought and Amethyst mines the sulphide ore is cut in places by seams of black manganese oxide, and the amount of gold in parts of such ore is conspicuously greater. The minerals of the sulphide ore include pyrite, sphalerite, galena, and a little chalcopyrite; probably some argentite is present also. The sulphur compounds of arsenic and antimony have not been noted.

#### SECONDARY ENRICHMENT

In many deposits of copper, silver, and gold the ore near the surface is of relatively low grade and is unworkable. At greater depths richer ore is found, and at still greater depths such ore gives way to lower-grade sulphides. These relations are generally assumed to indicate that the metals have been dissolved out of the upper portion of the orebodies and have been redeposited lower down. The leached portions of the deposits are in general highly oxidized. The richer portions are only partly oxi-

dized, whereas the lower-grade ore in the deeper portions of the deposits shows comparatively little alteration. Briefly stated, many deposits may be divided into four zones: (1) an oxidized leached zone at or near the surface; (2) an oxidized or partly oxidized zone of richer ore below the leached zone; (3) a zone of rich sulphides below the rich oxidized zone; and (4) the lower-grade primary sulphide ore below the rich sulphides.

These relations are indicated by the vertical distribution of the richer ore of the Amethyst vein. The horizon of the richest ore is in general from 200 to 800 ft. below the surface, although such ore extended to the outcrop between the Amethyst and Last Chance shafts. The upper portion of the richer zone was highly oxidized, but a considerable number of nodules and masses of sulphide ore was present in the lower portion and the number of these increased in depth. The oxidized ore is valuable for silver, chiefly as the native metal and the chloride, and lead, as the carbonate and sulphate. The proportion of gold to silver increased greatly below the thoroughly oxidized ore, suggesting a transfer of gold by descending waters. The lode is very strongly fractured and considerable oxidation has taken place along fractures and seams as deep as exploration has gone, or more than 1200 ft. below the surface. Limonite, set free by the oxidation of iron sulphides, and manganese oxide, liberated by the weathering of amethystine quartz, were deposited along some of these fractures. The great bulk of the ore in the lower levels carries from 6 to 20 oz. of silver to the ton, 5 to 15% of lead, \$1 to \$2 per ton in gold, and a variable percentage of zinc. Some of it is well within the limit of profitable exploitation, although it is considerably lower in grade than much of the more highly oxidized ore in the upper levels.

#### EXTENSION IN DEPTH

As bearing on the possibility of profitable developments below the adit level, inquiry may be made respecting the position of this level in the zone of secondary enrichment. If the adit is below the bottom of the altered zone, any orebodies that may be found below the adit will be primary. If the adit is above the bottom of the zone of alteration, bodies of enriched ore may be expected. One would be bold indeed to prophesy in advance of development that such orebodies will or will not be found, yet there is some evidence that bears directly on this point.

With respect to the distribution of silver, it may be stated frankly that no bonanzas comparable to those which were worked in the upper levels of the mines have been developed within 100 ft. of the adit level. Stopes have been raised at many places from the adit, but they are small compared with those higher in the vein and, as already stated, the ore in them is generally of lower grade. The evidence of decrease in value alone, however, does not warrant the conclusion that the bottom of the zone of possible enrichment has been reached. The state of the ore with respect to alteration processes is important in this connection. At the southeast portion of the vein, in the Bachelor and Commodore mines, comparatively thorough oxidation extends to greater depths than in the mines on the lode farther north. At some places a considerable amount of oxidation has taken place in the Bachelor mine within 100 ft. of the adit, and on the Commodore claim, which lies just north of the Bachelor, a stope called the Wire Silver stope was raised from level E, which is just above the Commodore tunnel. The bottom of this stope is about 225 ft. above the Nelson drainage adit and about 1200 ft. below the surface. Although this stope was not accessible, the presence of wire silver in the ore is regarded as an indication of secondary alteration. A winze that was sunk below the adit in the Bachelor mine is now filled with water, but according to report some sulphide ore of shipping grade was developed.

The fracturing of the lode is very great, and the secondary fracturing is complicated, the ore being much more permeable at some places than at others. On the whole, however, the circulation of water from the surface

is exceptionally vigorous, owing to the highly fractured condition of the ore. These observations lead to the conclusion, therefore, that the adit level in the Bachelor and Commodore mines is probably not below the bottom of the zone which is marked by partial secondary alteration of the ore. Whether processes of enrichment have gone far enough to make exploration of this part of the lode profitable is a question which cannot now be answered.

The northwest end of the lode, as already stated, is not so thoroughly oxidized in the lower levels as the southeast end. Nevertheless, the sulphide ore in the lower levels of the Last Chance, Amethyst, and Happy Thought is crossed by numerous fractures in and along which limonite and manganese oxide have formed. Some of the ore which is cut by stringers of these oxides is low-grade concentrating ore. Locally, however, this ore contains considerable gold. There is not much doubt that the gold of this ore has been increased somewhat by secondary processes, for the association of gold with manganese dioxide is significant of such processes. For example, in the Happy Thought mine on the Amethyst vein between levels 7 and 8, a body of partly oxidized ore composed of galena, zincblende, copper carbonates, cerussite, and anglesite contains a conspicuous amount of manganese dioxide, which coats the older sulphides and occurs in fractures cutting the partly oxidized ore. A considerable tonnage of this ore concentrated in the Humphrey mill yielded \$20 in gold per ton, and some of it ran as high as \$100 per ton. This figure is of significant magnitude, for the average content of gold in the Happy Thought ore is about \$2 per ton.

In reviewing these facts, it is pertinent to inquire whether they warrant the expectation of any enrichment of gold below the adit level in the north end of the Amethyst vein. It has been shown that gold in these relations is found in stopes just above the adit level, but so far as is now known, the enrichment of gold due to secondary deposition at this level is not great. The present methods of concentration, however, permit the recovery of lead, silver, zinc, and gold, and in much of the ore the gold value is rather subordinate. Silver is comparatively low in these levels, but so far as is indicated by the data available, there is no reason to suppose that lead and zinc will be less abundant in the zone 200 ft. below the adit than in the zone 200 ft. above it, provided, of course, that the ore of the vein maintains an equal width.

In connection with the possibilities of profitable development below the adit level, certain considerations other than the changes in the character of the ore in depth merit attention. The amount of water which issues from the portal of the adit is very great, and most of it is collected in that part of the adit which is driven in or near the vein. No notable quantity of water is added in the portion of the adit that cross-cuts the country rock. In sinking a deep winze that was put down in the foot-wall in the Commodore mine, pumping charges were high, and they would doubtless have been higher if the cross-cuts had been run to the vein. Owing to the highly fractured condition of the vein, any project which contemplates deep exploration should provide for handling a considerable proportion of the water now draining from the adit. Some of this drainage could probably be kept out of lower workings, but extensive stoping below the adit would surely increase the flow.

THE annual report of the Chemical, Metallurgical & Mining Society of South Africa shows that there were 1229 members at the beginning of June. W. R. Dowling was elected president for the forthcoming year. Revenue from subscriptions amounted to \$7550, while the net cost of publishing the society's journal was \$4060. There was a deficit of \$1630 on the year's work. During the year 30 technical papers on all mining and metallurgical subjects were read by members.

STAMP-DUTY of Rand mines increased 0.69 tons per day in 1911, as against that of 1910.

## Training of Mine Employees

By M. W. VON BERNEWITZ

A good deal of attention is being directed to the better condition and education of men working in mining fields throughout the world, and on the Rand there have been several discussions on the subject of late. At the June meeting of the Chemical, Metallurgical, and Mining Society of South Africa, F. J. Pooler read a paper entitled 'The Surface Workers on the Rand and Their Technical Education'; at a meeting of the Society of Civil Engineers, H. Bromley read a paper on 'The Training of Artisans and Skilled Operators in South Africa'; and on 'The Training of South African Miners', Mr. Schumacher made some interesting remarks at a meeting of the Transvaal Chamber of Mines.

In the first-mentioned paper it is said that, since June 1909, the Consolidated Goldfields company has made an organized effort to employ young white men on its surface work; the experiment has so far justified itself as to become a settled policy. The Rand Mines, Ltd., also instituted a scheme on somewhat similar lines, a special 'White Labor Department' being created to deal with the matter. The paper dealt with the learners and apprentices who came under such schemes as the above, or who are working in the mines where no special scheme is in existence. In the conditions of service the learners are informed before applying for posts that the work they are called upon to do is hard, and therefore good physique and grit are a necessity. Mr. Pooler said that, from personal experience, he noticed this point had not been fully realized by some of those appointed during the past three years. Though work may commence in the mills, for those who have done well, after a reasonable period, other surface work of a less arduous nature is found. The following table should be of some interest, showing results at the Consolidated Goldfields mines:

	Number.	Per cent.
Total learners employed .....	220	
Still employed December 31, 1911.....	105	47.73
Employed in other departments, or groups .....	28	12.73
Left of own accord .....	73	33.18
Dismissed as unsuitable .....	14	6.36

Some dissatisfaction has been expressed as to the wages paid to learners at different mines, but this seems to be unfounded, considering the rates, per 8-hour shift, on the length of service as shown below:

	Months.	Wages.
Employed less than.....	6	\$2.08
" over .....	6	2.42
" .....	12	2.42
" .....	18	2.94
" .....	24	3.53
" .....	30	3.64

These figures show that this scheme offers a reasonable prospect of advancement to any youth who cares to do a fair day's work, and sink his personal dislike to dirty hands in his determination to succeed.

Mr. Pooler did not intend to discuss the relative merits of the technically trained and the practical man, as both are absolutely necessary for carrying out any work. A member of the Society had stated that there were not enough practical experienced men in charge of the underground operations; but it is certain that in reduction works there cannot be too many technically trained men, so long as these men are also conversant with the details of the processes they supervise. In April 1912 the *South African Mining Journal* drew attention to the regrettable fact that many of the more recent improvements in metallurgical practice had had their origin in America. It may be that the local younger generation is not taking as full advantage of the facilities provided by local institutions as might be reasonably expected. The white labor department of

the Rand Mines, Ltd., informed Mr. Pooler that, of 275 learners, there were only 30 attending the Transvaal School of Mines and Technology during 1911, but there were more during the present term. It is more than likely that, in future, regular attendance at one or the other of the technical classes will be an indispensable condition before a learner obtains promotion. From data supplied by the principal of the above institution, it appears that there were 131 students on the roll, of whom 62 were learners and apprentices. From official figures issued by the government inspector of white labor at the end of 1911, it appears that there were employed on the Rand 1493 mill-men (excluding litters), 1137 cyanide men, 309 samplers, and 174 assayers and assistants; a total of 3113. Of these, there were 261 mill and 223 cyanide learners and apprentices. From this comparison it is obvious that many men are not taking advantage of the facilities provided in the various grades of chemistry, metallurgy, and assaying. Besides the above classes, between 130 and 140 mine apprentices were attending preliminary classes of all kinds during the first term of 1912, some of these men being engineering apprentices.

In discussing the reasons for failure, Mr. Pooler asks, "Is one of the main reasons for this failure to take advantage of educational facilities, not due perhaps to a distrust of scientific method and theory of any sort?" Many inventions come from practical men, but how many more labor-saving devices might there have been if more of those who have risen from 'among the ruck' had known how to apply scientifically the many useful hints acquired in the day's work? This lack of interest in things scientific can scarcely be put down to the charge of the heads of the departments of the mining industry on the Rand. Mr. Pooler is inclined to think that more enthusiasm is shown for technical training by engineering students. Of course, men working regular shifts find it impossible to attend classes regularly, and even may not be in fit condition for so doing. Some are materially unfit to benefit by instruction, and many are not fitted to benefit because of deficiencies in their preliminary education. In conclusion, it is important to note that the exigencies of the labor market demand that white men technically trained shall be in charge of the surface work on the mines.

In the discussion following this interesting paper, W. A. Caldecott regretted the general attitude of workers. Position and pay at 20 years of age matter comparatively little, but at 40 they are all-important, hence the favorable conditions for acquiring knowledge and experience through study and varied training in the earlier years should be utilized. The Americans say: "Theory is worth nothing, practice alone is worth \$5 per shift, and the combination may be worth anything." Others who discussed the paper shortly, but effectively, were J. E. Thomas, E. J. Laschinger, S. Newton, and C. Toombs.

Mr. Bromley, in his paper read before the Society of Civil Engineers, contended that for the proper training of tradesmen, operators, skilled laborers, overseers, and unskilled laborers, it is essential to have: (1) compulsory education up to the sixth standard grade in the case of tradesmen, and up to the fourth in the case of others; (2) the indenturing of apprentices to the various trades; (3) the providing of local night classes or trades schools; (4) the providing of practical instruction from first-class tradesmen; (5) the opportunity for training tradesmen, skilled workers, operators, and laborers in the undertakings of the Union of South Africa; and (6) the rearrangement of the scale of wages to attract the class of men required.

Mr. Schumacher, speaking before the Chamber of Mines, said that his group of mines employed 603 learners on the surface and underground, and there were more underground learners at the Village Deep than at the Wolhuter school. The Crown Mines has 120 learners underground, of whom half are Dutchmen. Five years ago Mr. Schumacher was a member of the committee which reported to the Government on the question of establishing a training school. The Government was recommended to take an

entire mine, in which students should actually take over the work. On a basis of crushing with 60 stamps, there would be needed 420 apprentices after three years, thereafter putting out 35 trained miners every three months; that is, there would be an intake of 35 learners and an output of 35 trained miners every three months. The scheme failed for the reason that no suitable site could be obtained. He would again recommend the Government to test ground which had been opened, and believed that the mining companies would support them financially as they were prepared to do in 1907 and 1908.

In Germany every facility is afforded mine employees to study and better themselves, many companies insisting on men being technically trained to some degree before employing them. It has been said that every foreman at the Mansfield copper mines and plant had had a good scientific training. While indirectly connected with mining, the practice of the Brunner Mond Chemical Co. is of interest. This is probably the most skilfully managed chemical industry in Great Britain, and perhaps there is no industrial undertaking, even in Germany, more scientifically administered. Since its foundation there has been 'no resting on oars,' but an ever striving forward policy seems to dominate the officials, and even the workmen. The employees have every facility afforded them to study and improve their position. It is compulsory for apprentices, not only to attend evening technical classes, but those held during certain days as well. The company contributes to a sickness and maintenance fund, to enable men to retire in comfort. Sir John Brunner once said, "the men who make the profits should participate in them."

In most of the important mining centres of Australia and New Zealand there are good public primary and private secondary schools, continuation classes, technical schools, and schools of mines, especially catering to men working at mines and mills. The most important are at Ballarat, Bendigo, Charters Towers, Kalgoorlie, Thames, and Zeehan, while there are several others in smaller centres. The Mt. Morgan company has been liberal in its help to the local school in the town mainly supported by its operations. Beside these, Adelaide has a large school of mines, while Auckland, Brisbane, Dunedin, Melbourne, and Sydney have universities where mining in all its branches may be studied. To what extent are these schools of mines used in the mining centres? On the whole, they are attended to a fair degree, but not nearly what they should be. At Kalgoorlie there are about 5800 mine employees, and under 200 attend the local school of mines, which is large, well equipped for every class of student, caters to men working shifts, and offers, along with the Chamber of Mines, valuable scholarships and prizes. A large number of young people in the town, apart from mine employees, attend night classes. The wages paid and general conditions at Kalgoorlie have attracted a good class of workers, and their general efficiency is high, as is proved by the low costs prevailing in the district; lower comparatively than on the Rand with colored labor. From several years' observations, I must say that there seems to be a feeling of 'don't care' or 'cannot be bothered' among the majority of mine employees. They do their work in good style, but after it is finished there is little desire to read or to try to improve themselves. There are numbers of men who rarely read the daily newspaper; and many who do, only study the sporting page. Throughout Australian mining districts the sporting element is too prevalent altogether. Apart from these men, there are others, especially in mills, who take great interest in their work, read at work if there is spare time, and study at some technical school. Such men get on. Managers at Kalgoorlie are not slow in recognizing merit. There are two splendid libraries in the district, yet out of say 20,000 adults only about 1500 are members, and the majority of these are business people. Miners and millmen are comfortably provided. Each company has first-class change houses, and men can go to work in good clothes and after work can be thoroughly clean. Conditions of work are also decent on the whole. Of course, the summer

heat partly accounts for the careless attitude toward study. Nearly all the large mines generally make room for a few learners or cadets, and they are given as much assistance as possible. Cadets at some mining camps complain that they are kept in one department too long, and there may be room for objecting to being so placed. The trouble with some students is that they think they should take it easy, having been given employment under some influence or other. There have been cases where they got through the day's work and then gave themselves up to all sorts of enjoyments till late hours, further study being seldom thought of. This class of learner will never get on. On the other hand, there have been cases of hard and determined work, and such men are sure to advance. Every encouragement is given to employees of the Mt. Lyell and Broken Hill companies, and suggested improvements to plant are always carefully considered, and, if valuable, credit is given the man making the suggestion. Men in the Zeehan district of Tasmania have good opportunity to study at the local school of mines. In New Zealand, at the Reefton, Thames, and Waihi mining camps, many men have done well at the school, but many miners are too busy with labor troubles to bother about study.

In the United States there are many technical schools, and much has been written on sociological conditions at certain centres, and how large companies try to help their men to advance their position or make them more contented, but in many cases few bother themselves. In summing up, it might be said that although everybody cannot be in charge of mines and mills, yet a little effort on the part of mine employees would make work more interesting and life more satisfactory.

## Gulkana and Susitana Placers

The U. S. Geological Survey has just issued Bulletin 498, 'Headwater Regions of Gulkana and Susitana Rivers, Alaska,' by Fred H. Moffit, a report which deals primarily with the district including the Valdez creek gold placers, but also gives an account of mining developments during the past few years in the Slate Creek district, at the head of Chistochina river. Slate creek and its gold placers were visited by W. C. Mendenhall in 1902 and were described by him in Professional Paper 41. Mr. Mendenhall also visited Delta river in 1898, but the region west of Delta river, including the head of Susitna river has never been described geologically before the field work of 1910, on which Bulletin 498 is based, was undertaken. During the summer of 1910, D. C. Witherspoon, assisted by C. E. Giffin, made surveys for a topographic reconnaissance map to be published on a scale of 1 to 250,000, or about 4 miles to 1 in. This map is the base of the geologic map accompanying the report.

## Feldspar Production

The year 1911 showed the largest production ever recorded in the feldspar industry, the output being greater by 901 tons in quantity and \$20,064 in value than that of 1907, the year of maximum production until 1911. The production in 1911, according to a report on feldspar and quartz by Jefferson Middleton, just issued by the U. S. Geological Survey, was 92,700 short tons, valued at \$579,008, against 81,102 short tons, valued at \$502,452, in 1910. In 1911 deposits in California, Connecticut, Maine, Maryland, Minnesota, New York, North Carolina, Pennsylvania, and Virginia were worked. Maine led all the other states in quantity produced, with 25,976 short tons; New York was second, with 18,800 short tons; Connecticut third, with 16,497 short tons; Pennsylvania fourth, with 13,284 short tons; and Maryland fifth, with 12,694 short tons.

REVENUE of the Union Government of South Africa derived from mines in the Transvaal from May 31, 1910, to March 31, 1911, amounted to \$8,350,000. This was the result of government ownership and taxes on mining.

## A Mine Model

By MAXWELL C. MILTON

As models are becoming more and more a part of the working apparatus of large mines, a description of several made by the Copper Queen Consolidated Mining Co., of Bisbee, Arizona, may be of interest.

The ores of this mine occur in bodies of irregular shape, separated by greater or less intervals of waste, and are found distributed over an area of approximately two square miles. Practically all the ore is mined by the square-set system, the floors being 8 ft. apart, with levels at 100-ft. intervals. Filling is carried on contemporaneously with stoping and, in general, no attempt is made to rob the stopes of the timber used for holding the ground.

In the summer of 1911, fire was discovered in the filled

celluloid upon which each floor is carboned from tracings made from the stope maps. The floors are then cut out with a 10-ft. band saw, electrically driven. A little practice enables one to cut to a line, so that filing is necessary only to remove the saw marks. The paper is then removed from the celluloid, the parts assembled and cemented with the following solution:

Dissolve 1 part gum camphor in 4 parts alcohol.

Dissolve equal weight of shellac in the above solution.

This cement sets quickly and is very strong. Alcohol will also do as a cement. The sides of the stopes are painted with conventional colors to represent the different grades of mineralized ground left. The completed stopes are placed on the glass levels as the final step.

The model can be kept up to date easily, and the cost is not large, the principal item of expenditure being labor. There is some danger from fire, but experiments indicate that nothing short of a flame will start the celluloid blazing.

SECTION OF MODEL IN FRAMES.

ONE LEVEL FROM THE MODEL.

portion of a large orebody from which extraction was still going on. As the shape of this body was very irregular, a model was planned to aid in showing the best places for cutting off the burning sections from unmined ground, and in general to prevent the fire spreading. After some experimenting, celluloid was found to be the best material for use in the model. The information obtained and the results achieved by the use of this model, were so satisfactory that it was decided to show the most important portions of the mine in a similar way, as the method used shows very clearly the irregularities of the ore, and also correlates different orebodies on different horizons and sometimes gives a clue to possible ore extensions.

It was decided that the standard scale of the mine maps, 1 in. to 50 ft., would not only give sufficient size for showing the stoping work done in detail, but would save considerable labor in making working plans. With this scale, it was impracticable to make the model in one frame, so it was made in sections that could be placed side by side. A maximum size for easy handling was found to be 36 in. square. The frames were made with four 1-in. posts, set on pine foundations, 4 in. wide by 1½ in. thick. The centre of the foundations are occupied by ground glass for illuminating purposes. At proper intervals, ¼-in. iron bars are dove-tailed into the posts, for supporting the levels, the posts being grooved so that each level can be taken out of its frame independently. The posts are kept in alignment by oak strips joining the tops. All frames rest on a table fitted with electric light, so placed as to throw an even illumination on each model, from below.

Each level is represented by plate glass, on which drifts, claim lines, sill-floors of stopes, etc., are traced from the map. Ordinary drawing ink is used, the drifts, etc., being colored in solid. The tracings are given a coat of shellac to prevent them from flaking off when dusted. The stopes are cut from transparent celluloid, bought in sheets, of such thickness as to represent eight feet. Paper is pasted on the

The accompanying photographs show a typical level, and the assembled sections so far built.

GOLD has been found in its bedrock source in the slate area south of Valdez creek in Alaska and is present in some of the stream-gravel deposits within that area. Most of the placer gold from this district, however, has come from an old filled-in channel or canyon once occupied by Valdez creek and from the stream-gravels of that part of the present channel of the creek which lies below the point where the old and new channels intersect. The gold in the new channel is in large part a re-concentration from the rich auriferous filling of the old canyon. This old channel represents an earlier stage of the topography on which the present stage is superposed, the whole process being closely connected with the intense glaciation which this region has undergone and which is not yet completed. The old channel and the three or four creek claims below it on the present stream constitute an excellent example of the importance of re-concentration in the production of rich gold placers. The region was recently studied by the U. S. Geological Survey.

SLATE CREEK is 75 miles east of Valdez creek. It is the site of an older camp than Valdez creek, and with its tributary, Miller gulch, has been the greatest producer of placer gold within the Copper River basin, having yielded more than \$1,500,000. Its gold is derived from a mineralized area in slate. Diorite intrusive rocks are present, and in these respects the deposits resemble those of Valdez creek. It is believed, however, that the slate of Valdez creek is younger, although the diorite intrusives are probably of the same or nearly the same age. The richest gold deposits of Slate creek and Miller gulch are approaching exhaustion and the district has reached that stage where its future will depend on the introduction of more economical means of mining than have been used in the past.

# Comparative Method of Screen Analysis

By A. T. TYE

The standard method of screen analysis used at the concentrating plant of the Cananea Consolidated Copper Co. is the wet one. General samples from the fine jigs, Wilfley tables, and vanners of each of the four sections of the plant, are taken each shift. A certain weight of each of these samples is taken, and put in dust-proof, galvanized-iron boxes. Therefore, there are three samples of each tailing per day, or about ninety per month. At the end of the month, each of these composite samples is carefully cut down to about 1000 gm. A screen analysis is made, giving the percentage of weight and the assay of the material on each different screen. This method is followed year after year, and the results recorded in the office. The value of this method lies in the fact that results obtained by any new system of classification, or by an increase or decrease of size in the screen aperture of the Bryan mill, may be compared to the previous average monthly composite screen analyses over a long period, and the beneficial or detrimental results determined with great accuracy.

The Cananea screen analysis system is carried to a point which gives much additional information. As 100 gm. is taken as a sample for screen analysis, the percentage of weight is at once read off without any chance of error, and there is sufficient material available to make a careful panning test on the material remaining on each screen. The mere percentage of weight, and the assay of each screen size gives only part of the information wanted, and may be misleading, from the fact that each screen size contains some free concentrate mixed with the true clean tailing and does not give the lowest tailing possible on each screen. If, for instance, there should happen to be a larger amount of free concentrate in the coarse tailing than in the succeeding finer size, it would appear to show that the concentrate was included in the gangue and would require fine-grinding. By panning this material, however, the fallacy of this supposition is at once made apparent, as the produce would be a small amount of rich concentrate, and a tailing much lower in copper than the general assay for that screen size, and also lower than the next finer screen assay of clean tailing.

The screens used at Cananea for analysis are the Tyler standard testing sieves, and have the following apertures as given by the manufacturer and tested by micrometer:

Mesh.	Inch.	mm.
20 .....	0.0335 .....	0.8509
60 .....	0.0091 .....	0.2311
100 .....	0.0055 .....	0.1397
200 .....	0.003 .....	0.0762

The method of wet-screening analysis at Cananea is as follows: The first sieve to be used, say 240 mesh, is placed on a wire triangle over a deep copper bucket, and a kilogram of tailing is placed upon the screen. Clear water is added at one side, and the material in the immediate vicinity is gently stirred by the fingers, keeping the screen clear in that part, so that the slime may be carried through the screen as fast as possible. Gradually all the material is worked over in this manner until all the slime has passed into the bucket and only sand remains upon the sieve. After the sand is once free from slime, the screening goes on fairly rapidly. For certain trials it is preferable to add the tailing to be de-slimed in small amounts, de-sliming and removing the clean sand alternately for each lot treated. With coarse material, such as Wilfley and sand-jig tailings, the de-sliming may require only three minutes, whereas with vanner tailing, rich in slime, it may require ten minutes. The de-slimed sand is next placed on the coarsest-sized screen to be

used, say 20-mesh, and a small amount of water added while the screen is kept in motion. This carries through most of the material of finer sizes into the copper pan below, which is placed at one side and the screen placed in another similar pan and water added. Any additional sand passing the screen is removed from time to time and added to the sand first passing the screen. After the more easily screened sand has been removed, the screen is given a jiggling motion which is continued until no more sand will pass it. This point is sharply defined, as white sand shows up very distinctly through the clear water against the red copper of the pan. As soon as a fair quantity of white sand has passed the screen it is removed and added to that previously collected, so that the grains are not crushed under the rim of the sieve. The jiggling motion is continued with the frequent addition of clear water until no more sand passes the sieve. The sieve is then inverted and the sand remaining on the wires is carefully washed out upon a drying pan, 10 by 12 in. by 1 in. deep. The pan is placed in a drying oven heated by steam.

This method is very simple and gives exact results. Although the concentrators treat ores from different ore-bodies, yet the average mixture in 60,000 tons per month appears to be quite constant; so that, so long as no changes are made in the classifiers or screen system, the percentage of the same tailing remaining on any particular screen will give almost identical results every month. An ordinary screen analysis from 20-mesh to slime requires a little more than two hours, including time of weighing the screen size. On account of the large number of screen analyses required daily without increase in the number of operators, during tests on products of the Richards-Janney classifier, and comparative tests between the Hardinge and Bryan mills, it was decided to make experiments to determine if some other method or modification of wet screening would not give as accurate results in less time. The following results as to time and accuracy were secured. They are instructive in showing the composition of the tailing of the concentrators of the Southwest treating hard and soft ores.

## TRUE VANNER TAILING

Test No. 1.	Copper, %.		Weight, %.	
	Wet.	Semi-dry.	Wet.	Semi-dry.
On 100.....	0.33	0.28	2.76	2.52
On 200.....	0.29	0.35	7.64	9.14
On 240.....	0.35	0.37	11.15	9.02
Through 240.....	0.95	0.87	78.45	79.32
Time, minutes .....			105	50

The regular wet grading-analysis was made as previously described. On an equal amount of the same material a semi-dry screen analysis was made. This was done as follows: The tailing was de-slimed as in wet-screen analysis, but instead of continuing the process wet, the de-slimed sands were dried and screened dry. The small amount of material through 240-mesh obtained by dry-screening was added to that previously obtained by the de-sliming process.

The variations which may occur in the assay of the same sample of this material is about 0.05% Cu for the sand, and about 0.10% Cu for the slime, and this applies to all other assays given. This is the variation allowed in every-day work where several hundred assays are run.

## TRUE VANNER TAILING

Test No. 2.	Copper, %.		Weight, %.	
	I	II	I	II
On 100.....	0.39	0.28	3.12	2.95
On 200.....	0.24	0.27	7.80	8.50
On 240.....	0.41	0.39	11.50	9.75
Through 240.....	1.00	0.88	77.58	78.80

These wet-screen analyses were made on different days, but upon different samples of the same general sample of tailing, to learn of any variation in the daily work.

## TAILING FROM FINE SAND PLANT

Test No. 3.	Copper, %.		Weight, %.	
	Wet.	Semi-dry.	Wet.	Semi-dry.
On 100.....	0.27	0.29	12.62	14.42
On 200.....	0.27	0.31	17.74	18.05
On 240.....	0.56	0.51	15.00	13.05
Through 240.....	1.05	1.06	54.64	54.45
Time, minutes .....			120	70

This test was made on intermediate material, between vanner, jig, and Wilfley tailing, to secure a correct average and determine if the results found with the vanner tests agreed with the fine and coarse sand tests.

## WILFLEY AND FINE JIG TAILING (SOFT ORE)

Test No. 4.	Copper, %.		Weight, %.	
	Wet.	Semi-dry.	Wet.	Semi-dry.
On 20.....	0.45	0.44	9.05	9.27
On 60.....	0.44	0.47	36.20	36.22
On 100.....	0.39	0.39	20.65	22.54
On 200.....	0.43	0.47	11.90	11.07
On 240.....	0.99	1.07	5.35	5.50
Through 240.....	1.27	1.36	16.85	15.40

The average variation in weight between wet-screen analyses on the same sample was 0.97%, and the same in semi-dry analyses. The average variation in assays between wet analyses was 0.07% Cu, compared with 0.04% Cu in semi-dry work. Wet analyses took 120, compared with 75 minutes in the semi-dry method.

## WILFLEY AND FINE JIG TAILING (SOFT ORE)

Test No. 5.	Wet.		Dry No. 1.		Dry No. 2.	
	Wt.	Cu, %.	Wt.	Cu, %.	Wt.	Cu, %.
On 20..	4.85	0.40	6.12	0.43	6.00	0.47
On 60..	38.87	0.40	41.08	0.44	41.00	0.44
On 100..	24.45	0.40	26.68	0.40	27.20	0.43
On 200..	4.87	0.48	16.60	0.48	16.00	0.52
On 240..	7.35	1.07	1.20	0.88	1.52	0.73
Through 240..	20.68	1.27	8.32	1.33	8.28	1.32
Time taken, minutes..	130		30		25	

Taking the wet analysis as standard, the dry analysis shows an error of over 18% in weight with soft ore, and an average variation of 0.15 to 0.25% Cu compared to 0.07% Cu in wet analyses. On the other hand, the dry screening required only one-fourth the time necessary for wet screening.

## WILFLEY AND JIG TAILING (HARD ORE).

Test No. 6.	Dry.		Dry.		Wet.	
	Wt.	Cu, %.	Wt.	Cu, %.	Wt.	Cu, %.
On 20...	16.76	0.28	17.20	0.28	15.80	0.24
On 60...	49.72	0.28	49.48	0.28	48.90	0.24
On 100...	15.20	0.21	15.40	0.21	14.25	0.24
On 200...	8.80	0.24	8.92	0.24	7.45	0.21
On 240...	0.88	0.35	0.96	0.35	1.00	0.25
Through 240...	8.64	1.07	8.04	1.07	12.60	0.98
Time taken, minutes..	30		43		135	

The variation in weight between the ordinary dry-screen analysis, and the dry analysis with extra time on each sieve, gives a difference of only 0.84%. With hard ore the error in weight by dry-screen analysis is only 4.6%, instead of over 18% with soft ore, which slimes considerably. The assays show a difference of about 0.13% copper.

In conclusion, it may be said that semi-dry screen analysis gives almost identical results as complete wet-screen analysis, both as to weight and assays, and the former can be made in about half the time required for the latter. Duplicate dry analyses check each other quite closely, both as to weight and assays, showing that about the same amount of fine material remains with the coarser particle in each test. Thanks are due to F. J. Strachan, superintendent of the plant, for permission to publish the results of the above test.

ROCK-DRILLS numbering 4671 were at work in the Transvaal gold mines in 1911.

## Determining Pitch of Gears

By DOUGLAS WATERMAN

Having had occasion to determine the pitch of partly worn gears with a view to ordering new ones, I was confronted by a problem, the solution of which could not be found in any of the standard hand-books nor in the manufacturers' catalogues. While it is possible to forward the makers a templet of the gear, and this is recommended in the case of special patterns, it is not only more convenient but safer to specify the exact pitch of the gears. It is a necessity if the gears must be ordered by cable. The notes taken during a study of this subject and a description of the method finally adopted for determining the exact pitch of gears are given in the following text.

When ordering gears the important dimensions are: (1) pitch diameter; (2) pitch; (3) number of teeth; (4) face; (5) bore; (6) keyway in hub; (7) distance through hub (if space on shaft is limited); (8) backing (if gears are bevel, angle, or mitre).

A comprehensive definition of 'pitch circle,' 'pitch diameter,' and 'pitch' is given in Kent's 'Mechanical Engineers' Pocket Books,' as follows: "If two cylinders with parallel axes are pressed together, and one of them rotated on its axis, it will drive the other by means of the friction between the surfaces. The cylinders may be considered as a pair of spur wheels with an infinite number of very small teeth. If actual teeth are formed upon the cylinders, making alternate elevations and depressions in the cylindrical surface, the distance between the axes remaining the same, we have a pair of gear wheels which will drive one another by pressure upon the faces of the teeth, if the teeth are properly shaped. In making the teeth the cylindrical surface may entirely disappear, but the position it occupied may still be considered as a cylindrical surface, which is called the 'pitch surface,' and its trace on the wheel, or a plane cutting the wheel at right angles to its axis, is called the 'pitch circle' or 'pitch line.' The diameter of this circle is called the 'pitch diameter,' and the distance from the face of one tooth to the corresponding face of the next tooth on the same wheel, measured on an arc of the pitch circle, is called the 'pitch' of the tooth or the 'circular pitch.'"

'Circular pitch' and 'diametral pitch' are expressed in the following formulae:

$$\text{Circular pitch} = \frac{\text{Pitch diam. in inches} \times 3.1416}{\text{Number of teeth}} = \frac{\text{Circumference}}{\text{Number teeth}}$$

$$\text{Diametral pitch} = \frac{\text{Number of teeth}}{\text{Diam. pitch circle}}$$

Some makers design their gears to circular pitch expressed in even fractions of an inch, as: 1, 1½, 1¼, 1⅓ in.; others in diametral pitch, as: 3, 3½, 4 pitch. Gears designed on both these systems are frequently found on machines having two or more gears.

The relation between diametral and circular pitch is given by the following table, taken from Kent's 'Pocket Book':

Diam. pitch.	Circular pitch.	Diam. pitch.	Circular pitch.
1	3.142	2¾	1.142
1½	2.094	3	1.047
2	1.571	3½	0.898
2½	1.396	4	0.785
2½	1.257	5	0.628

In determining the pitch, either diametral or circular, it is necessary to know the diameter of the pitch circle. I found it impossible to measure the pitch diameter with any degree of accuracy, especially if the teeth are worn, owing to the difficulty of judging the point on the tooth through which the pitch circle passes. This will be seen from the figure, which shows the position of the pitch circles with respect to the teeth of the engaging gears. There is a way, however, of determining the pitch diameter that gives close

results. An example taken from my notes will serve as an illustration.

MOTOR HOIST			
Drum Gear.		Inter-Pinion.	
Total diam. gear...	33 5/16	6 13/16	
Depth of tooth....	7/8 scant (0.80)	7/8 scant (0.80)	
No. teeth .....	74	14	
Inter-Gear.		Motor Pinion.	
Total diam. gear....	20 3/4	7 1/4	
Depth of tooth ....	9/16	9/16	
No. teeth .....	81	27	

There are two measurements that can be taken accurately from the gear. These are the total diameter of the wheel, and the depth of the tooth. If then some relation can be found between the depth of the tooth and the portion outside the pitch circle, we can calculate the

diameter of this circle, which is smaller than the diameter of the wheel by twice the distance of that part of the tooth without the pitch circle. The required relation is shown in the table, also from Kent, in which the circular pitch is 1 inch.

Depth of tooth above pitch line...	0.35	0.30	0.37	0.33	0.30
" " " below " " ...	0.40	0.40	0.43	...	0.35
Total depth of tooth.....	0.75	0.70	0.80	0.75	0.65

This relation varies slightly with teeth of different depths and pitch, but a close approximation is found by multiplying the total depth of the tooth by the factor 0.46. The calculations are much simplified by converting the fractions of an inch into decimals.

The calculations for the drum gear would be as follows: The total depth of the tooth being 0.80, the part without the pitch circle, or the 'face' of the tooth, is found to be 0.37 (0.80 × 0.46 = 0.37). Twice this number subtracted from the total diameter of the wheel gives us the pitch diameter.

Pitch diam. = 33.185 - 2 × 0.37 = 32.44 in.

Substituting in the formula:

$$\text{Circular pitch} = \frac{\text{Pitch diam.} \times 3.1416}{\text{Number of teeth}}$$
$$= \frac{32.44 \times 3.1416}{74} = 1.377 \text{ in.}$$

Examining the table to see if this corresponds to a standard diametral pitch, and finding that it does not, one judges it to be 1 3/8 in. circular pitch (1.375), which varies only in the third place from the one that has been calculated.

The inter-pinion which engages it must have the same pitch, and here there is a check on our calculations. The inter-gear and motor pinion are found to have a pitch diameter of 20.25 and 6.75 in., respectively, and by inspection we see at once that it must be 4 diametral pitch, since

$$\text{Diametral pitch} = \frac{\text{Number of teeth}}{\text{Pitch diam.}} = \frac{81}{20.25} = 4$$

and

$$\frac{27}{6.75} = 4$$

The full specifications for ordering these gears would be as follows:

MOTOR HOIST	
Drum Gear.	
No. teeth .....	74
Pitch diam. ....	32.38 in. (corrected)
Pitch .....	1 3/8 in.
Bore .....	2 7/16
Face .....	3
Keyway in hub. 5/8 by 1/4	
Inter-Gear.	
No. teeth .....	81
Pitch diam. ....	20.25 in.
Diametral pitch ...	4
Bore .....	1 13/16
Face .....	2 7/8
Keyway in hub.....	1/2 by 1/4
Inter-Pinion (double shrouds).	
No. teeth .....	14
Pitch diam. ....	6.1 in. (corrected)
Pitch .....	1 3/8 in.
Bore .....	1 13/16
Face .....	3 3/8 (bet. shrouds)
Keyway in hub. 5/8 by 1/4	
Motor-Pinion (raw-hide double shrouds).	
No. teeth .....	27
Pitch diam. ....	6.75 in.
Diametral pitch ...	4
Bore .....	1 5/8
Face .....	3 (bet. shrouds)
Keyway in hub.....	3/8 by 1/8

It is to be regretted that manufacturers do not in all cases stamp the pitch and diameter on their gears, thus avoiding all danger of a mistake when ordering spares. Much time may be saved by the management if all important gears are listed for future reference, and the purchasing agent furnished with a copy; each gear being designated by a code word.

Prospecting in the Yukon

The 'chechaco,' or newcomer, entering the Yukon to prospect should receive a little preliminary instruction before launching into the wilderness. He cannot start into the Yukon to spend the winter without enough money to defray the cost of a winter's outfit. If he leaves Whitehorse in the summer, the trip down the Yukon river may be made by steamer or in small boat. It always is easy to arrange accommodation. By buying in a Canadian town, goods entering the Yukon will not be subject to duty, but it is best, all things considered, to buy an outfit in Dawson; or, for one not coming into Dawson, to buy at Whitehorse. By buying in this territory, he has the benefit of experienced and scrupulous traders, who know just what is adapted to this region, and who will assist in selecting the best for the peculiar work to be undertaken.

The prospector should leave Dawson in August or September. At this time the summer floods are over, flies are less troublesome, and game and fish are plentiful. Whenever possible, the prospector should go by boat. For shallow, swift, and narrow rivers, a boat 30 ft. long, of 26-in. bottom, and 22 in. deep is the best. Having procured his boat, 150 ft. of 1/2-in. hemp rope, and a pair of rubber boots, the prospector next selects and loads his provisions, always bearing in mind that articles less likely to be damaged by water should be placed in the bottom of the boat.

The outfit for twelve months should comprise the following: Flour, 500 lb.; rolled oats, 150 lb.; cornmeal, 50 lb.; beans, 7 lb.; sugar, 125 lb.; Lubeck potatoes, 60 lb.; butter, 50 lb.; apricots, 25 lb.; prunes, 25 lb.; apples, 25 lb.; milk, two cases; cream, two cases; ham, 25 lb.; bacon, 50 lb.; salt, 15 lb.; pepper, 1 lb.; syrup, 5 gallons; baking powder, 2 lb.; baking soda, 2 lb.; yeast cakes, 6 boxes; soap, 12 lb.; best pilot bread, 30 lb.; candles, two boxes; tobacco; best woolen underwear, three suits; thick over-shirts, 3; thick woolen sox, 12 pairs; German sox, 2 pairs; woolen pants, 1 pair; overalls, 3 pairs; felt shoes, 1 pair; rubber shoes, 2 pairs; moccasins, 3 pairs; insoles for moccasins, 6; snowshoes, 1 pair; pack straps, 1 set; eye-glasses, colored, 1 pair; good field-glasses, 1 pair; reliable

[\*Writing in the Dawson Weekly News, Robert Henderson, discoverer of the gold in the Klondyke valley, makes such pertinent and detailed suggestions regarding outfitting for prospecting in Yukon Territory, that we reproduce the letter entire.—EDITOR.]

compass; fur robe; fur cap; canvas jacket; sweater; axes, 2; small camp axe; auger,  $\frac{1}{2}$ -in., 1; cross-cut saw, 4 ft.; whipsaw; jack-plane; nails, 15 lb., 10-penny; clawhammer; flat files, 2; sheath knives, 2; three-cornered files, 2; sharpening stone; picks, 2; shovels, 3; gold-pans, 2; Yukon stove with oven or drum; .30-.30 Winchester rifle; good shotgun; 200 rounds for shotgun; 200 rounds for rifle; frying pan; knife, fork, and plate; small pots, 4; large enameled mugs, 2.

The outfit should include a small medicine chest, among the contents of which should be one box of carbolic salve and a half-pint bottle of peroxide of hydrogen or other equally good antiseptic. One gallon of concentrated lime-juice should be taken along to make a pleasant and invigorating drink, and it will be a most effectual preventive of scurvy. The tent should be 10 by 12 ft. in size. It serves, when not in use, to cover the outfit, a precaution that should never be neglected either in the boat or in camp.

The prospector will have no difficulty in providing himself with fresh meat. The country abounds with moose, bear, caribou, mountain sheep, geese, ducks, ptarmigan, partridges, and grouse, and cranes and swans alight on the bars of the upper rivers by the thousands. Beaver, land otter, marten, lynx, wolf, fox, wolverine, and other fur-bearing animals are plentiful around the upper reaches of Yukon side streams.

On the trail in severe weather, always make camp while there is plenty of daylight. Never travel in foggy or stormy weather; always have matches and dry birch-bark ready to make a fire quickly. Eat regularly, even if you are not hungry. Keep your hands and feet dry, and—don't forget your tobacco.

It is well on a trip of this kind to take two or three good dogs and a Yukon sleigh. The dogs cost little to feed in a game country. The sleigh can be packed in the boat and will be useful for moving camp from creek to creek. Make a good warm shelter for the dogs and feed them at night.

To keep the outfit while in camp, cut four trees a few feet apart, and 12 ft. from the ground. Pick off the bark, and build a platform on top and let it extend about three feet on each side beyond the supports. Place supplies on top and cover with canvas and spruce boughs. They are in this way protected from animals.

In building a cabin, make it big enough. It takes little longer to build a cabin 16 by 12 than one of less dimensions, and this is large enough for all requirements. Level off the ground, and let the first logs be imbedded in it. Cover well with moss and lay the next log on top, and so with each log until the walls are six feet high. The logs forming the gable must be pinned together with  $1\frac{1}{2}$ -in. wooden pegs, and the ridge-pole laid in place. A smaller log on each side of the ridge-pole further supports the roof, which is made of poles three or four inches in diameter, laid side by side and covered with moss and earth. Whipsaw a few boards to make a door. Pieces of moose skin make good hinges, and a clean flour sack steeped in melted tallow or oil makes a good substitute for glass.

Your partner on a prospecting trip should be a man with whom you are well acquainted, and of jovial and optimistic disposition. Avoid arguments, especially of a religious or political nature, and the golden adage, "A kind word turneth away wrath," is no where so forcibly realized as in the wilderness.

CAMP BREAD is easily made by the Lake Superior rule: one spoonful of baking powder for each cup of flour with one spoonful of salt for the batch. Mix in water with the least possible stirring and bake quickly.

## Lead and Zinc Production by Regions

By B. S. BUTLER and J. P. DUNLOP

\*The productive lead and zinc territory in the central states naturally falls into seven regions, three of which are not limited to any single state. For practical purposes it seems desirable to compile the production by the natural regions irrespective of state lines.

The seven regions are as follows in order of importance of output: (1) The Joplin region, comprising the district in southwest Missouri, southeast Kansas, and northeast Oklahoma; (2) southeast Missouri, containing the great disseminated lead deposits; (3) the upper Mississippi Valley region, including all the lead and zinc mines in southwest Wisconsin, Iowa, and northwest Illinois; (4) the Kentucky-Illinois fluorspar region in southern Illinois and northern Kentucky; (5) central Missouri (owing to the small output from this region for convenience it has in this report been included in the southeast Missouri region); (6) northern Arkansas; (7) the Arbuckle Mountain region in southern Oklahoma.

The Southeast Missouri region produced 78% of the lead

PRODUCTION OF LEAD AND ZINC IN THE CENTRAL STATES IN 1911 BY REGIONS, IN SHORT TONS

Region.	Concentrates.				Metal.				Total value of metal.

<sup>a</sup> Includes both galena and lead carbonate concentrates.

<sup>b</sup> Includes sphalerite, zinc carbonate, and zinc silicate concentrates.

<sup>c</sup> Includes a small production from the Central Missouri region.

output of the central states and about 35% of the production of lead from domestic ore in the United States in 1911. The Joplin region produced 19% of the lead and 78% of the zinc of the central states in 1911, and was much the largest producer of zinc in the United States, yielding about 50% of the total zinc production. The Upper Mississippi region produced 2% of the lead and 20% of the zinc produced in the central states in 1911.

L. VOGELSTEIN & Co. report the following figures of German consumption of foreign copper for the months January to June 1912:

	Tons.
Imports .....	107,944
Exports .....	5,072
Consumption .....	102,872

These figures may be compared with consumption during the same period in 1911 of 86,188 tons. Of the above quantity, 93,523 tons was imported from the United States.

LUCKY GULCH, a small branch of Valdez creek, contributed an important amount to the gold production of the district, and Rusty creek promises to become a producing stream also. Mining on Valdez creek has been carried on under difficulties arising from high cost of transportation and labor, shortness of working season, and other troubles such that it could not have been profitable if the gravel had not been remarkably rich. The gold production of Valdez creek, including that of 1910, is probably not far from \$275,000.

\*From Advance chapter 'Mineral Resources of the United States, 1911,' U. S. Geol. Survey.

## Western Australia Gold Output

The June gold output was valued at \$2,271,000, the principal returns being as follows:

Name.	Tonnage.	Yield.	Profit.	Div.
Gt. Boulder Proprietary.	18,336	\$230,830	\$120,640	\$328,120

## Hand Drilling v. Machine Drilling

A unique drilling contest took place at Calumet, Michigan, August 24, when one man with a 'Butterfly' rock drill defeated a three-man team of hand-drillers. Each party was allowed 15 minutes of actual drilling; at the end of that time the hammer and drill team had drilled 49 in., breaking their record set a few weeks previously at the miners' picnic, by a quarter of an inch. The man with the machine-drill holed through the rock, 60 in., with one minute to spare, winning the prize of \$50. The hammer and drill team was composed of the winners of the hand-drilling contest held at the miners' picnic, William Billadeau, Matt Kramerich, and Charles Seppala; the man with the machine drill was John Becker. The rock-drill used was an Ingersoll-Rand, Butterfly valve, one-man machine. Two other contests were held at the same time, which were essentially trials of speed in 'rigging-up' one-man and two-man machines. Each team was required to 'rig-up' its machine, drill for two minutes (to show that the job was a satisfactory one), and then put in a new drill steel.

In the two-man contest there were 20 teams entered, practically every mine in the copper country being represented. The Ahmeek team, composed of Patrick Dunnigan and Archie Paulson, won the first prize of \$100, and did the work in 3 min. 42 sec., taking only 1 min. 42 sec. to 'rig up' and put in the drill. The Calumet & Hecla Amygdaloid team won the second prize of \$50; the Wolverine team won the third prize of \$25.

In the one-man drill contest there were 17 teams entered. The Calumet & Hecla Amygdaloid team won the first prize in 4 min. 33½ sec., John Bosio constituting the team. Allouez took second, and Wolverine third. The prizes were the same amounts as in the two-man contest. The two-man drill used was of Ingersoll-Rand make; the one-man drill was an Ingersoll-Rand Butterfly machine. The contests in rigging-up drill machines are in line with the recent policy of the Calumet & Hecla M. Co., which is conducting a thorough campaign in efficiency engineering in underground work. The company has coöperated with rock-drill manufacturers to secure the construction of a light one-man ma-

chine to be used in drifts which will equal or exceed the speed of a two-man machine. It is reported that the expense of changing from the two-man to one-man machines will aggregate a quarter of a million dollars, but such astounding reductions are being attained in cost of driving and stopping that this sum will be made up in the saving of the first year or two. The innovations were first tried out in the Superior mine and were so successful there that they are now being introduced in the other mines of the company.

## Guggenheim Exploration Company

A circular recently distributed gives interesting details regarding this company, which was organized June 5, 1899, for the exploitation of mining properties, and it holds large interests in many of the most important mining concerns in the United States. The company's authorized capitalization is 880,000 shares with a par value of \$25, making \$22,000,000. Of this there is outstanding 831,732 shares at \$25, or \$20,793,300. The par value of the stock was changed on April 17, 1912, from \$100 to \$25, and the number of issued shares increased from 207,933 to 831,732. The company has no bonded indebtedness. The assets are as follows:

American Smelters Securities Co. 'A', 154,000 shares at \$95 .....	\$14,630,000
American Smelters Securities Co. 6% bonds, par .....	1,500,000
Utah Copper Co. stock, 404,504 shares at \$3.50.	9,693,736
Alaska-Yukon properties and equipment, at cost	1,170,230
Miscellaneous investments at cost.....	24,438
Cash and demand loans as at December 31, 1911	7,721,933
Chino shares, 36,600 at \$34.....	1,134,600
Total .....	\$60,549,681

This is equal to about \$73 per share on the present outstanding capital. Since the formation of the company, results have been satisfactory and earnings have steadily increased. The full effect of operations at the Utah Copper, Yukon, and Chino properties has not been felt, as they have yet to reach their maximum productions. In the past three years profits of the Guggenheim company have increased from 11 to 17.7%, as the following table will show:

Year Ended	Surplus.	Profit.	Dividends	Profits in excess of dividends.
Dec. 31, 1909...	\$13,857,064	11.0	\$2,074,840	\$ 213,376
" 1910...	15,124,589	16.1	2,079,330	1,267,524
" 1911...	23,474,178	17.7	2,079,330	1,602,440

The officials of the Guggenheim company include the following: President, Daniel Guggenheim; vice-president, Morris Guggenheim; directors, D. Guggenheim, M. Guggenheim, I. Guggenheim, S. R. Guggenheim, L. Friedrich, C. K. Lipman, P. Yeatman, H. P. Whitney, G. S. Field, J. H. Hammond, and O. B. Perry; treasurer, Leopold Friedrich; secretary, C. K. Lipman; assistant secretary, D. A. Crockett; purchasing agent (New York), H. K. McGowan; general manager and consulting engineer, P. Yeatman.

## Copper Producers' Association Report

The Copper Producers reported September 9, the copper stock on September 1 to amount to 46,701,374 lb., as compared with 50,280,421 lb. August 1. Production in August was 145,628,521 lb., while in July it was 137,161,129 lb. Domestic deliveries amounted to 78,722,418 lb., as against 71,094,381; and foreign deliveries 70,485,150, as compared with 60,121,331 in August. Total deliveries were 149,207,568, against 131,215,712 in July. This is the smallest surplus reported this year, save on July 1, when it was 44,335,004 pounds.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Genesis of Lead-Silver Ores in Wardner District, Idaho

The Editor:

Sir—In the August 3, 1912, issue of the *Mining and Scientific Press*, F. L. Ransome has entered a protest against the form of expression used by me in referring, in my paper under the above title,<sup>1</sup> to the work of himself and F. C. Calkins. I had no intention of antagonizing the United States Geological Survey or any member of it. Realizing that anyone who took the trouble to compare my map with that portion of Mr. Calkins' map which covers the same area, might gain a misconception of the cause of the great difference, I undertook to intimate that it is a question largely of the time spent by each of us in the district, using, therefore, the statement that, "Mr. Calkins found that the structure in the Wardner district is too complex and obscure to enable him to do any but very generalized mapping in the time that he could give to the work." I believed I was warranted in this statement because on page 66 of Professional Paper No. 62,<sup>2</sup> Mr. Calkins says: "The structure is most complex and also most obscure in the quartzitic rocks near Wardner. Here the mapping must be considered as greatly generalized." Surely Mr. Ransome cannot object to my suggestion that Mr. Calkins' map would have been more detailed had he been able to give more time to the district.

Mr. Ransome seems to have taken especial exception to my use of the word "visited" in referring to his examinations in the district. I used the word deliberately, not with any intention of disparaging his work, but because I believed its use was accurate and proper. Soon after beginning work underground in the Bunker Hill mine, I learned, that in the upper workings accessible to Mr. Ransome, the fault, which had earlier in the history of the Bunker Hill, Stemwinder, and Tyler mines, been known as the 'Wardner foot-wall,' diverges from the foot-wall toward the east and downward, so that the foot-wall of the broad vein is made up of two faults of widely differing ages. This is a simple, clearly established, and important fact in the Wardner mines, but, if recognized by Mr. Ransome, there is no intimation of it in Professional Paper No. 62. Furthermore, he seemed to have overlooked abundant and clear evidences that the orebodies were formed in several stages, associated with different sets of fractures. Now I have for some years considered Mr. Ransome one of our strongest economic geologists; I, naturally, jumped to the conclusion that he did not make a detailed study of the Wardner mines, but that his investigation was of the nature of a reconnaissance underground, such as one would make on a prolonged visit. But if Mr. Ransome prefers, I will withdraw the term and replace it with *study*, though I will continue to deny that it was a *detailed study*. If he spent two weeks in the district, he must have covered the accessible underground openings at a rate of more than a mile a day which, in such a complex region, is a mere reconnaissance.

My paper as published was extracted from a much larger paper in which I had proposed to treat the geology of the Wardner district from every standpoint, giving due credit to the work of others. I concluded to cut it into several smaller papers, one of which should treat the faults at length from the standpoint of 'pure geology', and an-

other, the bearing of geology on the mining operations of the Coeur d'Alene district; hence, I cut the economic paper down to bedrock. But I could not very well avoid some reference to the published work of the Government geologists. The men who really are entitled to have a grievance against me are the geologists and engineers whose work I have not mentioned.

I would have been delighted to have had Mr. Ransome's company while I was giving "leisurely attention" to the geology of the Wardner district. During the first 40 days I climbed about 120,000 ft., an average of 3600 ft. per day. I do not believe it is discreditable to me for having spent many days wrestling with those "soil-mantled and brush-covered slopes," thus evolving a system which is being successfully used in the search for new orebodies in the mines of the district.

The Coeur d'Alene region is the most difficult for geological field-work in which I have ever studied, because there is so little lithologic contrast between several of the formations, and especially between the surface debris from these formations. I can make, in a week in the desert country, a map more satisfactory to myself than I can in six months in an equal area in this country; hence, no one can better appreciate the value of the work done by Ransome and Calkins. I have always felt that Mr. Calkins' subdivision of the rocks was as good as could be made; my further subdivision of several of the formations in the Wardner district is only locally practicable. But Mr. Calkins frequently could not distinguish his own formations. For instance, I began work with a copy of his map in hand, to familiarize myself with the characteristics of the different formations. Later, I had to unlearn much. A number of small areas that were mapped as St. Regis I found are so related structurally to undoubted Burke rocks that they must be early Burke in age. At first I was strongly inclined to criticize him, but after leaving some of his Burke in the St. Regis for several years because of its purple color and being obliged to reclassify it as Burke because underground work failed to develop a fault between the purple rock and undoubted upper Burke, I feel more lenient. In a few places where small areas of a certain formation have been mapped, there is nothing remotely suggesting it, though the vicinity usually yields something that may have been the origin of the mapping. I have generally attributed this to the difficulty of inexperienced assistants determining their position with reference to the topographic map. I believe the same statements apply, though in lesser degree, to the entire Coeur d'Alene district. In the eastern portion of the district, where the structure is simple, the mapping is fairly good, but where Mr. Calkins has mapped faults there are usually others of equal structural importance; at least that has been my experience. Mine-owners and other geologists are learning that the details of the map are in many places useless for their purposes, if not even harmful. In making this statement I have no intention of arraigning Mr. Calkins. It was a physical impossibility for him to make, in six months of field-work, a map of a country like this, approaching to accuracy in detail. My map of a very small fraction of the Coeur d'Alene district, made public after several years of work, I do not consider beyond criticism. I expect in time to change some of its details as underground work is extended. Mr. Calkins' map is useful when properly understood. But I think that when a man is sent out to cover in two seasons a difficult and exceedingly complex region like the Coeur d'Alene district, the Survey should insure that the report shall clearly impress on the reader that the time given to the work was not sufficient to attain to any high degree of accuracy in the details, so that mine-owners and the general public will not place too implicit confidence in it. It is not to be supposed that the Survey can afford to carry on, in any one of the many mining districts demanding its attention, such an intensive study as the Bunker Hill & Sullivan Mining & Concentrating Co. has had conducted by myself and other geologists, and therefore I am not criticizing it for issuing Profes-

<sup>1</sup>June 1, 1912, pp. 750-753; June 8, 1912, pp. 786-790; and June 15, 1912, pp. 825-827.

<sup>2</sup>'Geology and Ore Deposits of the Coeur d'Alene District, Idaho.' U. S. Geol. Surv., Prof. Paper No. 62, 1908.

sional Paper No. 62 after the limited amount of field work that was given to the district, but I am endeavoring to defend myself against Mr. Ransome's implied charge of unfairness for having intimated an explanation for Professional Paper No. 62's treatment of the Wardner district.

The general tenor of Mr. Ransome's communication indicates that he questions the existence of many of the faults which I have attempted to map and the practicability of dividing them into nine systems, each representing a distinct period and stress; he asks how I establish "so definitely that the nine systems of faults are of different ages and that each system has associated with it a distinct type of mineralization." I can show an attrition gouge or breccia for each of over 75% of the faults, and the others are necessary to explain the juxtaposition of formations which were originally not in contact. I never put a fault on the map when it is possible to explain the observed facts otherwise. I determine the relative ages of faults under the simple principle that where one fault has cut and displaced another fault, the displaced fault is the older; or, in some cases, by the fact that one fault has cut and displaced a mineralized zone whose mineralization is clearly younger than some other fault. When a number of faults appear to be of about the same age and to be due to a stress acting in the same direction, I group them into a system. That I have been able to do this so elaborately in the Wardner district is simply a proof of the advantage of time in geological work. The relative age of the faults having been determined, the recognition of different stages of mineralization followed as a matter of course. It is not very difficult to determine the age relation between a fault and a mineral deposit. Incidentally, I may say that the paragraph in which Mr. Ransome refers to "12 distinct and successive periods of 'mineralization'" indicates careless reading of my paper. The chief argument that I can offer in defense of the system which I have worked out is that it is meeting the critical test of development work and is aiding in the discovery of new orebodies—it is probably wrong in some details, but the principle is good.

My statement that "normal faulting made stronger gouges than reverse faulting" referred to the Wardner district, and was based on the observation of over 75 gouges; as Mr. Ransome has seen very few of these gouges, he is not qualified to question it. For stating that "gouges were distinctly inimical to the deposition of mineral" without crediting the idea to Professional Paper No. 62, I hereby make humble apology.

As to the disseminated siderite, the "conclusion previously introduced in the field," that it is not older than, but was derived from, the monzonite magma, studied in the light of all the statements in Professional Paper No. 62, amounts to no more than an *impression* on the part of Mr. Ransome. He does not present any evidence directly connecting it with the monzonite batholith, but does show that ferrous carbonate was not deposited, by solutions emanating from the batholith, in the contact metamorphic zone. To this I add evidence that the metamorphic silicates, in at least one place, replaced a carbonate which was disposed in the manner characteristic of the disseminated siderite. He states that Mr. Calkins finds that siderite "is most abundant where the rocks have been most folded and fissured," but this in nowise necessarily points to the monzonite as its source. In view of this fact, I think I am entitled to have the "impression" that the oldest form of siderite in the district is too widely disseminated to be reasonably referred to the action of the monzonite magma, and that it antedated the intrusion. The metamorphism to which I referred as being older than the dissemination of siderite in its present form is the regional metamorphism discussed by Mr. Calkins on pp. 74-75 of Professional Paper No. 62.

Tourmaline, it appears, is widely distributed in the sedimentary rocks of the Coeur d'Alene district. While "it is most abundant where the rocks have been most disturbed," Mr. Calkins shows that the tourmaline in the contact metamorphic zones "forms stouter individuals than commonly

occur in the rocks not altered by the monzonite." May not the widely disseminated finer form be the product of the regional metamorphism referred to above?

That any of "the materials for the orebodies as they were successively formed were leached from older deposits" I am unable to prove, although I gave some evidence suggesting the derivation of at least some of the Blue Bird type from the disseminated lead-zinc mineralization. I suppose most of the leaching to have occurred far below the present deepest level in the Wardner mines. The idea was merely an "impression" on my part, gained from a study of the distribution of the mineralization in the various stages.

I now come to the one matter of real importance at issue between us—the question of the source of the lead, zinc, and silver of the Coeur d'Alene district. That "the ore constituents, inclusive of the siderite but probably exclusive of some of the quartz, were given off as emanations from the deep-seated portions of the slowly crystallizing batholith" of quartz monzonite is an assumption which is unsupported by any decisive evidence. "Among the facts adduced" by Mr. Ransome in support of this conclusion "was the mineralogical connection, through deposits of intermediate character, of the orebodies of the Wardner type with others in the same region that are genetically connected with contact metamorphic action." As he has shown, the district contains several ore deposits, notably those at the Granite and Sixteen-to-one mines, which are unquestionably of a contact metamorphic character. The lead and zinc sulphides were in large part deposited contemporaneously with the garnet and other contact metamorphic silicates. These silicates were formed while the sediments adjacent to the intruded mass were highly heated; in other words, at about the time of the intrusion. After the monzonite had crystallized to the depth of several thousand feet, the zone which was sufficiently heated and compressed for the formation of the metamorphic silicates had probably subsided beneath the contact metamorphic deposits; hence, the orebodies in the two mines mentioned above must have formed before the crystallization of the magma had reached its deep-seated portions. I have always understood the magmatic theory to imply that the gases emanating from the magma were expelled at the moment of crystallization; also, that as the solidification proceeds the portions remaining in solution becomes richer in the metallic elements. I do not understand that Mr. Ransome asserts that the ore constituents were to any extent derived from the upper portion of the monzonite, particularly from the monzonite off-shoots that reach the surface in the district.

No evidence is presented in Professional Paper No. 26 that lead and zinc-bearing gases rose through a great thickness of the liquid monzonite. There is, therefore, nothing known directly connecting the ores in the Sixteen-to-one and Granite mines with the deep-seated portion of the monzonite magma. All that these deposits demonstrate is that lead and zinc salts were accessible to the gases that emanated from the magma at or near the time of maximum intrusion, or to waters or vapors heated by proximity to the magma. They may just as well, and, in fact, with a little more probability, be held to have come from the sediments. It may be significant that the only typical contact metamorphic ore deposits in the district occur near the line of division between the Prichard and Burke formations, which is approximately the horizon at which I suppose the lead and zinc minerals may, originally, have been disseminated. Furthermore, it is not impossible that the lead and zinc sulphides had been subjected to concentration before the intrusion of the monzonite. The presence, in other mines, of contact metamorphic minerals, diminishing in strength of development away from the monzonite area, simply indicates their relation to the typical contact deposits. That there is a gradation to what Mr. Ransome calls the "Wardner type" means only that different mines present different mineralogical combinations. It does not prove that all these "gradations" were formed at

the same time or represent the same stage of mineralization. It does not prove that all the commercial orebodies or any of them, in the Wardner district, are of the same age as the contact metamorphic deposits in the basin of Nine Mile creek. To which stage in the Wardner district does Mr. Ransome apply the gradation? After the upper portion of the magma had solidified, he assumes that lead and zinc-depositing solutions continued to rise from the deeper portions of the batholith, but he does not present any evidence to show that these emanations came through the minute pores of the thick shell of crystallized monzonite, and does not point to any fissures in the monzonite as avenues of escape for the waters or gases. It is merely a working hypothesis; I endeavored in my paper to show that there may be another working hypothesis of equal value; that the source of the lead and zinc minerals may have been in a certain portion of the sediments. There is nothing inherently improbable in this, as it is fairly well established that the lead and zinc minerals in the great mining districts of the Mississippi basin were originally disseminated through the sediments. I did not pretend to prove my hypothesis and did not ask for its "general acceptance." The weak point in it is that I am not able to point to any one stratum in the sediments and give the amount of lead and zinc in invisible form that it may contain. I have always assumed that the laboratory at which my assays are made is not equipped to make the delicate determinations necessary in the case of a content as low as a few thousandths of a per cent. But I favor the hypothesis because it seems to explain the distribution of the vast majority, if not all, of the mines and prospects from the upper portion of the Prichard formation upward and to suggest an explanation for the fact that commercial zinc deposits are practically confined to the Prichard, whereas there is not sufficient mineralogical contrast between the formations to account for it as selective precipitation. I may finally adopt Mr. Ransome's magmatic theory, but at present the other appears to me to have the stronger support. I am searching for evidence.

In conclusion, I will say that I have been greatly and unpleasantly surprised at the tone of Mr. Ransome's communication. In several instances he misrepresents my position and then waxes eloquent in denunciation of it. My references, in the first part of my paper, to the work of himself and Mr. Calkins were not intended as a disparagement of their work, were not unwarranted by the facts, and have not justified the character of his protest. In the latter part of my paper I exercised the privilege which is due any geologist of dissenting from the opinions of another geologist. I did it without lack of respect to Mr. Ransome. His reply, however, has placed me on the defensive, and I have had to adopt his style to a certain extent. I will be pleased to continue the discussion, but along impersonal lines.

OSCAR H. HERSHEY.

Kellogg, Idaho, August 26.

### Railroad Mineral Lands

The Editor:

Sir—In your issue of August 24 appeared a letter from 'Prospector' relative to the miners interested in the mineral belt of northern California and southern Oregon, as affected by the claim of the Central Pacific Railroad Co. to mineral lands therein. The Miners' Congress held at Yreka, July 18 and 19 last, which was noted by you editorially and which was participated in by the miners and mining men of the whole region, gave the situation consideration. Two resolutions, which were passed by the Congress, will fully justify publication in your valuable columns. One deals with the railroad company's claims directly, and the other approves the work of the Forest Service and seeks to have investigations as to the mineral character of the disputed lands conducted with the aid of its officials. These resolutions are as follows:

Ever since the prospectors of forty-nine blazed the trails

over the Sierras and opened to the world the wealth of our gold mines, the policy of the United States, in recognition of their splendid service, has been to keep open to their class the mineral lands. This policy, incorporating as it has the miners' rules adopted at miners' meetings, into the laws of the land, after half a century trial has proved both its wisdom and its fairness. The prospector is still the greatest individual benefactor to the world's development. The 'grubstake' is still the most patriotic investment.

Contravening this policy and denying to the prospector these long unquestioned rights, the Central Pacific Railway is now claiming practically one-third of the great mineral belt, extending through Jackson and Josephine counties, Oregon, and Siskiyou, Trinity, and Shasta counties, California. This claim is in defiance to the express terms of its grant, and is against the very language of its patents. Believing this claim to be without right and that its blight upon the mining industry should be removed, not by driving the miner to engage at his own expense in litigation with that powerful corporation, but by government action without expense to the miner, just as is being done in case of the oil lands today; therefore, be it

*Resolved*, That the miners of southern Oregon and northern California, in this Congress assembled, do hereby respectfully request the proper federal and state authorities to take immediate steps within this mineral belt to have the mineral lands therein covered by claims or patents to the Central Pacific Railway Co. or its affiliated corporations or its predecessors in interest, exempted and segregated from said claims and patents and restored to public domain and to the right of the miner to prospect for and locate claims thereon; be it further

*Resolved*, That copies of this resolution, properly certified, be sent to the attorney-general of the United States, the director of the Bureau of Mines, our congressmen and United States senators, and the state mineralogists of Oregon and California; be it

*Resolved*, That it is the sense of this Congress that the Forest Service has proved an efficient agency, not only in preserving for the prospector the undiscovered mineral deposits in the district, by preventing their acquisition through non-mineral entries, but in facilitating their location, enjoyment, and patenting by good faith mineral claimants in accordance with laws passed in the interests of miners; and be it further

*Resolved*, That it is the sense of this Congress that the Forest Service employees in the field should be authorized to investigate, in connection with the miners, the lands covered by railroad grants and other non-mineral patents in the mineral belt, preparatory to government action in having such lands as are mineral exempted and segregated from lands properly held under such grants as non-mineral patent.

It is plain that where the railroad company accepted patents wherein appears the very plain reservation clause, "excluding and excepting all mineral lands should any such be found in said tracts," that it is as fully bound by the interests reserved as the Government is by the interest granted, and when the future tense is used, should any such be found in "said tracts," it is equally plain that probable subsequent segregation was in contemplation by both the Government and the company at the time the patent passed. It is also clear that if good faith has been and is to be observed between the Government and the railroad company, the fairest method of effecting the segregation will prevail. A thorough geological investigation is the first step demanded. This investigation should also be supplemented by tests by prospectors and miners. The segregation should be first done in the field, and it probably should be an arbitrary segregation, then very little will remain for the courts unless there is a resisting party, and if this resisting party is the most powerful corporation in the state of California it will not be quite fair to invite the prospector or miner to take up the gauge of battle. The Government should be the plaintiff.

Fully justifying suggestions have been made in the recent case of *Van Ness v. Rooney*, 169 Cal., 131, wherein the supreme court of the state approved the clear reasoning of Judge Bartlett of Trinity, who held that when patent was issued to the railroad company, containing the reservation clause quoted, that a mining claim within said tracts was specifically exempted from the grant of the patent, and title to it remained in the owner of the claim.

JAMES F. FARRAHER.

Yreka, August 27.

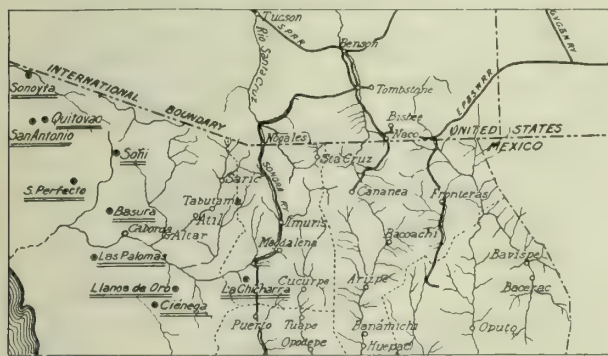

## Special Correspondence

### NEW YORK

LAKE COPPERS MERGE.—MEXICAN SITUATION.—COPPER AND THE RAILROADS.—COPPER MINE NEWS.—EL PASO CON.—NIPISING.—GUGGENHEIM DIVIDENDS.

An important consolidation is announced in the Michigan coppers. The Keweenaw is to absorb the Phoenix Consolidated Copper Co. and the Washington Copper Mining Co. The merger, as at present outlined, contemplates the taking in also of the Arnold Mining Co., the Ashbed Mining Co., and the Meadow Mining Co. The two latter concerns are controlled by the Keweenaw interests, and their absorption amounts only to a matter of bookkeeping. The Washington stockholders are to be given one share of Keweenaw for each twenty shares of stock now held, and the Phoenix shareholders are to come in on a basis of ten for one. The enlarged company will have something over 5000 acres of land on what is known as the Ashbed lode. As estimated by engineers, mining costs are about \$1, milling and smelting costs 50c. per ton, and with 14 lb. of copper per ton of rock it is figured that at 17c. the company's ores will yield a profit of 88c. per ton. The stockholders of the Keweenaw are being assessed \$2 per share to provide a treasury fund incidental to the merger.

The Mexican difficulties continue to be one of the chief deterrent factors in the mining situation. The beleaguering of the Phelps-Dodge plant at Nacozari, where the

NORTHERN SONORA, SCENE OF TROUBLE.

company's Moctezuma mine is situated, and the disorders at Cananea, where peace has prevailed until recently, give to affairs a more serious aspect than at any time heretofore. There are a great many questions being asked as to how and through whom the insurrectionary forces in Mexico are being sustained. The impression seems to be growing that some unseen figures are playing a prominent part in fomenting and continuing the troubles. The State Department at Washington is apparently impressed with the idea that anything like intervention on the part of this country would solidify all the country south of the Rio Grande in opposition to the rule of the *gringo*. At the same time it is hard to see how the disregard of personal and property rights of Americans can be tolerated much longer. There is a rather interesting story to the effect that sinews of war for the insurrectionists are being furnished by a syndicate of deposed Latin-American rulers, including Castro, Diaz, and Zelaya. The theory is advanced by Señor Herberto Barron, commercial agent of Mexico, who has just returned to New York after a six-months stay in his home country. Señor Barron was at one time a candidate for the presidency of Mexico. There are some ugly rumors afloat as to the part played, or supposed to be played, by 'big business' interests in Mexico and Nicaragua. Both in New York and London, mining markets are suffering from the present conditions. Issues such as El Oro, Santa Gertrudis, Esperanza, and

others that are traded in in London have marked time for more than a year. Notwithstanding the unfavorable conditions prevailing in Mexico, the Mexican Mines of El Oro has declared a dividend of 6 shilling per share, payable September 27.

There has been a great deal of discussion provoked by the announcement that the railroads were experimenting with a new formula for steel rails to contain 0.6% of copper. The statement was made that the St. Paul road had ordered some 5000 tons of steel rails to contain this amount. At present the statement cannot be verified, but there is a good deal that is of interest to be said concerning the use of copper in the manufacture of steel. At the present time there is only one regular steel product turned out by the United States Steel Corporation that contains any copper. Some time ago the Steel Corporation began making *terne* plates, for roofing purposes, containing a certain percentage of copper to give the steel additional weather-resisting qualities. These sheets are manufactured by the American Sheet & Tin Plate Co. A good deal of copper is used in various kinds of steel wire—piano wire being copper coated—and for this and similar purposes the Steel Corporation at present uses annually some 65,000,000 to 70,000,000 lb. of copper. One of the chief things to be considered in any experiments of this nature is the fact that the use of copper in railroading or similar purposes requires some years to complete satisfactory tests. The railroad companies can only arrive at any satisfactory conclusions after the compilation of carefully kept records extending over a period of time greater than that of the life of the regular rails now in service, and which are credited with an average life of from 11 to 13 years. While the possible new use of copper in this direction is extremely interesting, it is not a demand that can be created suddenly.

The insurgent crowd in the Stewart Mining Co. was unable to make any dent in the Heinze line of battle at the recent meeting held in Wallace, Idaho. The discontented shareholders, led by E. J. Carter, were recently soliciting contributions from shareholders for the purpose of paying court costs and expenses incidental to a suit for receivership. Evidently they were unable to accomplish anything within the company's breastworks and will be obliged to carry on their battle—if it is continued—from the outside. The shareholders of the Tuolumne-Copper Co. are a rather disgusted lot. August smelting returns show a production for the Tuolumne of less than 250,000 lb., which, in view of conditions prevailing in the metal market, is not satisfactory. The president, Edward Hickey, is quoted in a recent interview as saying that the mine has developed a great deal of first-class ore, but that he considers it good practice to get rid of a large amount of second-class ore that can be worked now at a profit; that dividends will be resumed soon, and when resumed will be continued. A new contract has just been made by the Tuolumne with the Washoe smelter providing for the handling of the second-class ores of the mine, and under the new arrangement the Tuolumne tonnage output should be trebled.

W. B. Thompson, who is head of the Inspiration Copper Co., returned this week from a protracted vacation in Europe, and in an interview stated that copper conditions abroad are everything that can be desired; that there is no copper in storage on the other side, and that Europe is watching the copper situation in the United States carefully. He also says that one firm of bankers in Paris has accumulated 250,000 shares of Utah Copper and is still in the market. English and Continental investors have long ago been taught to appreciate the possibilities of mines that can be turned to manufacturing propositions. It is undoubtedly because Utah Copper is such a shining example in this class that its shares have such support in France, where frugality and safety of investment are always the prime consideration.

The movement which has been proceeding in El Paso Consolidated is evidently preparatory to a wide campaign

of distribution. It is announced that a deal has been made whereby the minority holdings of 400,000 shares of stock have been purchased by a syndicate, thereby removing all opposition to the management of Mr. Burris, the president. These minority shareholders have been fighting the present management for some time, and it is presumed that with this opposition out of the way, the plans for taking some of the adjacent properties in Cripple Creek will be carried through. A meeting is to be held in Denver next week for the purpose of increasing the par value of the stock of the company.

The Nipissing Mines Co. is taking advantage of the primary market for silver in London, and is making its shipments direct to England. Some of the silver sold during last month netted more than 64c. per ounce. Nipissing is one of the Cobalt companies that is in a strong position financially, and notwithstanding the fact that its new mill for treating its low-grade ores has all been—or will all be—paid out of earnings, the company still has a surplus larger by \$100,000 than the surplus in the treasury this time last year. The new low-grade mill will go into commission in November, and thereafter the Nipissing will be a shipper of silver bullion only.

Hayden, Stone & Co. announces that the shares of the Alaska Gold Mines Co. were greatly oversubscribed at the initial offering, and allotments were generally cut down. The list of Guggenheim dividends, including Guggenheim Exploration, Yukon Gold, Utah Copper, and Nevada Consolidated, has been declared as usual without increase. It is expected that this line of securities will increase disbursements for the next quarter, and within a short time there will be some added dividend-payers. When Braden, Chino, Ray Consolidated, and Alaska Gold Mines are added the Guggenheim enterprises will have a very formidable front.

### LONDON

MOUNT MORGAN REORGANIZED.—BURMA MINES, LTD.—  
MEXICO MINES OF EL ORO ISSUES FAVORABLE REPORT.

The Mount Morgan Gold Mining Co. has been passing through a critical period during the past twelve months, but, owing to the fact that the bulk of the shares are held in large blocks by Australian owners, little has been heard of the crisis here, and not much in Australia. The trouble apparently began when the smelting of the auriferous copper ore was inaugurated, but it became acute when the pyritic ore from Many Peaks was substituted for the barren ironstone flux previously brought from Iron Island. The services of A. L. Dean, of the Mount Lyell mine, were requisitioned, and Robert S. Sticht has also been on the spot. The smelting plant has been organized, and the celebrated 'mundie works', where the pyritic gold quartz has been chlorinated for years, is to be abolished. It has never been known outside the works whether this chlorination process was an economic success or not, for no figures relating to the original content or percentage extraction have been published. Two years ago the gold ore of the oxidized and leached zone was exhausted, so in future the ore is to be treated solely by smelting. A great deal has been said from time to time about the high costs at this mine. For instance, during the last financial year the yield of gold and copper was worth 53s. 3d. per ton and the cost 44s. 5d. With the new management it is hoped to vastly increase the margin between these two figures. We are now informed that G. A. Richard has resigned as general manager and that Robert S. Archer, previously chairman of the board of directors, has been appointed managing director. Though copper has been an important factor in the output of recent years, and though in future the ore is to be treated by the methods of copper smelting, the mine is still a gold mine. During the past twelve months the gold output was 133,867 oz., and the copper output 4520 tons. This was from the Mount Morgan ore itself. In addition 2068 tons of copper and 718 oz. of gold were obtained from the Many Peaks fluxing ore. The ore re-

serve has been re-estimated, with the remarkable result that the gold content is now given at a substantially higher level. The figures on May 31 last were: 1,499,000 tons averaging 3½% copper and 10 dwt. gold, and 2,207,000 tons averaging 2½% copper and 5 dwt. gold per ton. A year previously the figures were: 1,543,000 tons averaging 3½% copper and 8 dwt. gold, and 2,070,500 tons averaging 3¼% copper and 2½ dwt. gold.

The company called 'The Burma Mines, Ltd.' is one of the most interesting projects in London. It was formed by Bewick, Moreing & Co. in 1906 for the purpose of acquiring ancient silver-lead mines and slag heaps at Bawdwin, near Lashio, in Upper Burma, not far from the frontier of China. The mines had been worked previously by the Chinese for the silver content of the ore, and the lead was an unconsidered item, to judge by the fact that the slag averages 45% in that metal. These workers had confined their attention to the oxidized zone, and the sul-

EASTERN AUSTRALIA, SHOWING POSITION OF MT. MORGAN.

phides disclosed through development by the present company contain a large proportion of zinc. Two years ago I mentioned that the expectations on flotation had been by no means realized, and that the company had had to be reconstituted on a new basis by drastically reducing the nominal capital, and at the same time assessing the shareholders. The affairs of the company are still being arranged with the object of putting it on a sounder basis. The smelter has been removed from Mandalay to the vicinity of the property in order to save the expense of transport; a refinery is being built so as to extract the silver and sell the lead in the Eastern markets, while prospecting and development have been actively prosecuted so as to give the company a source of ore instead of being dependent too much on the old slag heaps. The ore disclosed in the developments consists of mixed sulphides, running high in lead and zinc, with some iron and copper, and containing much silver. The ore varies greatly in content, but taking an average of the samples quoted in the report, it may be said to contain 8 to 20% lead, 10 to 33% zinc, 1 to 10% iron, 0 to 5% copper, and 5 to 25 oz. silver per ton. The gangue is mostly quartz. In view of the changed conditions due to the nature of the sulphide, large lots of the ore have been sent to London

for the purpose of determining the best methods of beneficiation.

As usual, the annual report of the Mexico Mines of El Oro affords interesting reading. The company used to be in control of the Exploration company. It was formed in 1904 to acquire from the Mexican Gold & Silver Recovery Co. a group of gold-mining claims situated to the north of the Esperanza mine, which in its turn is to the north of the El Oro Mining & Railway Co.'s property. The same vein, the San Rafael, is found on the property of all three companies. In 1910 the control passed from the Exploration company owing to the opposition of the Pearson and French groups of shareholders. Before the change of control, the Exploration company had issued several gloomy reports prophesying a diminution of the grade of the ore and a reduction in the amount of ore raised. The yearly reports subsequently published have not so far confirmed these warnings, but have shown a maintained production and increased ore reserves. André P. Griffiths is consulting engineer and Fergus L. Allan is manager. The report for the year ended June 30 shows that 142,205 tons of ore was raised and sent to the mill, averaging 9 dwt. gold and 6 oz. silver. The bullion recovered was worth \$1,555,095 or \$10.89 per ton, being an extraction of 87.3%. The English accounts show an income from the sale of bullion of £317,329. The working cost in Mexico was £128,029 or \$4.37 per ton; other current expenses absorbed £46,300. On capital account £14,985 was spent, and £10,000 was placed to reserve for income tax. The dividends absorbed £144,000, being at the rate of 80%. On June 30 Mr. Allan reported the ore reserve as 295,100 tons, assaying 9.14 dwt. gold and 5 oz. silver per ton. This is an increase of 76,000 tons as compared with the figures a year ago, and 110,000 tons more than at the end of June 1910. During the year a seventh tubemill was added, and the drag-classifier has been adopted in place of the cones.

### BUTTE, MONTANA

**ELECTRIFICATION OF BUTTE, ANACONDA & PACIFIC.—BUTTE & SUPERIOR MILL.—DAVIS-DALY CO. FINDS ORE ON NEW LEVEL.—AIR-HOISTS DISPLACING STEAM.—‘RUSTLERS’ TO BE ABOLISHED.**

Along the line of the Butte, Anaconda & Pacific railway the poles are now up, but wiring has progressed no farther than from Anaconda to the Silverbow county line. At this point the workmen demanded for this work the wages which prevail in Butte. As these are higher than the wages paid by the mining companies for linemen around the mines, the work was stopped and the men are on strike.

D. C. Jackling, general manager for the Butte & Superior Copper Mining Co., accompanied by George Bradley, mechanical engineer for the Utah Copper Co., F. J. Janney, F. J. Janney, Jr., T. B. McCormick, and R. W. Salisbury, all of Salt Lake City, are in Butte on a tour of inspection of the company's property. The concentrator will soon be in shape to run at its full capacity of 2000 tons per day, but the mine will be unable to deliver this amount until the new hoisting-engine, now being installed, is ready. This will mean a delay of about two months. It should be remembered that the name ‘copper company’ as applied to this organization is misleading, as the mine is developing zinc sulphide ores almost entirely. At Mr. Jackling's suggestion, some of the jigs in the mill have been replaced by Garfield tables.

The Davis-Daly Copper Co. has cross-cut one of its known orebodies on the 1900-ft. level. The orebody is of about the same width and grade as on the 1700-ft. level above.

The Anaconda Copper Mining Co. is rapidly displacing its steam hoists by those operated by compressed air. Twelve hoists of the new type for use in the manway compartments of the shafts have recently been ordered, and one of them has just been installed at the Tramway mine. Nearly all of the big hoists for handling ore are

already of the air type. The 12 new engines are of Nordberg manufacture, direct-acting under air-pressure of 85 lb. per square inch. As the air-pressure is about 25 lb. less than that for the old steam-engines, the cylinders are of larger diameter, being 28 by 48 inches.

A common sight in the past around the foremen's offices of all the mines has been the long line of ‘rustlers’, or men looking for employment, who collect around the surface workings waiting for the appearance of the foreman, thus delaying surface operations and frequently endangering their own persons. Furthermore, the system which permitted each foreman to select his own men has been unquestionably subject to abuse in certain instances, the men securing employment having to pay various ‘rake-offs’ to those instrumental in employing them. These objections are to be overcome shortly by the establishment of a centrally placed employment bureau for all the mines, where applicants will register. The foremen will then secure their men from this office.

### KALGOORLIE, WESTERN AUSTRALIA

**STAMPEDE TO KURNALPI.—LAKE VIEW IMPROVES.—GREAT FINGALL LOSES IN AFRICA.—LABOR UNIONS AND ITALIANS.**

Renewed interest has suddenly been centred on the Kurnalpi field, situated some 55 miles northeast from here, from the fact that three weeks ago two prospectors, Routledge and Graham, deposited in the Western Australian Bank at Kanowna, 718 oz. of gold won from a narrow vein at a depth of 40 ft. A week later excitement was increased when Geissner and Huffa deposited 400 oz., said to have been got at a depth of 4 ft., from a similar lead 2½ miles north of the previous find. In the first-named consignment there was one slug of 46½ oz., and in the latter another of 230½ oz. A big rush immediately set in, and already some 70 claims, comprising 1500 acres, have been applied for, on which the Government has drawn some \$3500 in rents and fees. In addition to this, nearly four times the area has been staked, the owners playing a waiting game, before the legal ten days expire, during which they must pay up or quit. As the journey by motor car can be done in three to four hours from here, it is needless to say all the mine managers around, beside hundreds of other speculators, including all doctors who own their motors, have been out and staked claims. There are fully 500 men on the spot, most of whom are camped in the old postoffice and police barracks, which have been vacant for ten years. The solitary hotel, which would have been vacated in another fortnight, is doing a roaring business in drinks, beside supplying 100 meals two or three times a day. The ground in question was well prospected in 1896-97 by the Octagon Explorers, Ltd., a London company, which has a cash working capital of \$250,000. Eight shafts were sunk to various depths down to 100 ft., and a lot of cross-cutting done, but without any profit. R. S. Black, now general manager at the Kalgurli mine, was in charge at that time. No work is being done at present, not even by the prospectors, but this state of things cannot last much longer, as work must start 30 days after application has been made. Of course this regulation can be dodged, as was the case at Bullfinch, by two or more parties staking the same ground, or at least overlapping each other. In such cases work must be suspended till the ground is surveyed, which may mean a respite of anything up to six months. It is impossible to predict how the field will turn out, but the general impression is that it will never be any good except to small operators; in fact, that there is little chance of any big profitable lodes, such as those at Kalgoorlie, ever being discovered.

The Lake View & Star is now earning a profit of \$200,000 on its nominal capital of \$1,000,000, or 20% per year, and dividends of 15% per year are foreshadowed for some time to come, and any surplus is to be retained as a reserve fund. The company is now running its treat-

ment plant by electricity provided by the Kalgoorlie Electric Light & Power Co., and it is estimated that by erecting a suction-gas plant and producing its own electricity, a saving of \$30,000 per year could be made, which would pay for the plant in two years. However, nothing is to be done immediately. Ore reserves are estimated at fully two-years supply on present output with large probable reserves. This can easily be seen, as in the Star mine no ore below 400 ft. is included, although three lodes aggregating 50 ft. in width have been partly opened down to 1100 ft. The main shaft on the Lake View, which has been at a standstill for seven years, has been re-started, and levels will be opened at 2000 and 2100 ft. when these points are reached. Since the mill was overhauled and extended a year ago, the duty per stamp has been increased from 5.58 to 7.18 tons per 24 hours, and costs reduced from \$4.52 to \$4.27 per ton. Even in the upper levels of the Lake View mine new orebodies have been discovered,

THE GOLDEN MILE.

since H. E. Vail, an American engineer, took control two years ago, and prospects have vastly improved since then.

The directors of the Great Fingall showed very poor judgment when they invested \$375,000 of the company's money three years ago in the Tarkwa Main Reef, a West African mine, which had been fruitlessly run by a London company for nine years without producing any gold. After exploiting this mine for three years, they now tell shareholders that they have had to use a portion of their profits from the Great Fingall mine to write off the West African investment as a bad debt. Judging from results, Bewick, Moreing & Co., the consulting engineers of the company, have done badly in all their ventures since the early days of Coolgardie. With regard to the Great Fingall, the mine has been opening up well after being a blank for 450 ft. between the 13th and 16th levels. At the 17th level there is a shoot 308 ft. long by 60 in. wide, worth \$9.30 per ton, and at the 18th level the shoot is 316 ft. long by 50 in. wide, worth \$11.25. This can only be mined through a blind inclined-winze from the 13th level, which makes it wholly unprofitable. It is reckoned that an expenditure of \$100,000 will be required to get over the difficulty. The company's balance is still \$390,000 in spite of other ventures.

Although the labor unions must give notice next month as to whether the current wages agreement is to continue or be abrogated after September 30, they appear to have taken no definite steps in the matter so far. At least the rank and file appear to have no inkling as to what is to occur, and naturally the Chamber of Mines is lying low. The latest phase of the Labor party's madness is to legislate against more than a fixed proportion of Italians and Austrians being employed on the mines. The question has been brought up in Parliament, and a letter was also written to the Chamber of Mines on the subject, but got no encouragement. A meeting was convened by the mayor of Kalgoorlie, to be held in the town hall, but ended in a fiasco, as none of the responsible leaders of the party would face the music. There is no question that the best Australian miner has no superior in the world, but an industry which employs 16,000 men must have a

large percentage of 'ne'er-do-wells' and wasters, and these howl longest and loudest. All the best men are employed at Kalgoorlie, and little is heard of the Italian here, but elsewhere they must be employed wholesale or the industry will be paralyzed, as it has been at Lawlers and Lancefield. It is practically moribund at Laverton. The Sons of Gwalia, after every pay-day, has several machines stopped owing to men not returning after their fortnightly spree. If at such times Italians are employed, there is a cry against foreigners taking the bread out of the mouth of the Australian. The slackness of a small percentage of the latter is the cause of the whole trouble, and if the present Labor Government legislates on behalf of these wasters, they will do irreparable damage to the mining industry. Even the wood-chopping industry, which is almost monopolized by foreigners, is to be included in the restrictive legislation suggested by the malcontents, although no self-respecting Australian will go 100 miles or more into the bush, as all have to do now to chop wood.

During its past financial year, the Kalgoorlie Electric Power & Lighting Co. made a profit of \$121,000, against \$90,000 for the previous term. The cyclone which blew down the transmission lines, cost the company \$15,000 for repairs. No dividend was paid on ordinary shares.

## BOSTON

SILVER MINES OPENING.—BUTTE CENTRAL PLANS.—ALASKA GOLD MINES.—BRASS TRADE ACTIVE.

The high price of silver is becoming an important market factor. Recently there has been good buying of Nipissing with a substantial advance in the price, attributed to investors looking for an increase in the dividend. In Butte there are said to be over 100 abandoned silver mines and workings, many of which the higher price will bring back to a producing basis. The Butte Central Copper Co. is hurrying the first two units of its new mill to completion this month. The Butte Central mill is exclusively to treat the low-grade silver ore capping the copper vein. The constructor, John Rothwell, of Denver, expects by concentration to recover from these ores 63.9% of the gold and 39.44% of the silver. By cyanidation he expects an additional recovery of gold and 43.35% silver, making the total extraction 99.22% of the gold and 82.79% of the silver. Should Mr. Rothwell's estimate hold good, the interests behind Butte Central expect to go largely into the treatment of low-grade precious metal ores in Butte.

Boston has to date paid little or no attention to silver properties, but now that it has taken up zinc and gold issues supplementary to copper, interest even in silver is expected. Not long ago Nevada Hills was listed on the Curb here, but it has not yet attracted the attention it has in other markets. Premature trading on the Curb in Alaska Gold Mines Co. stock, pending the allotment of subscriptions by the banking house having the campaign in charge, has resulted in a number of shorts being confronted with the probability of a squeezing. The subscriptions for this issue were unprecedented in mining annals, coming from all over the United States, together with England, France, and Germany. The amount of stock represented in the preliminary offering was subscribed for many times over, and fully 2000 shareholders were enrolled. The success of the Alaska Gold Mines flotation is following the success of the Butte & Superior as a zinc issue, and has started Boston toward becoming a general mining-share market.

At the present time the unprecedented activity of the brass manufacturing business is easily the leading factor of the copper trade. The American Brass Co., which is the largest consumer of copper in the world, is said to be short 1000 operatives. As the result of the strong domestic demand for copper, recently reinforced by renewed buying from Europe, Boston speculators look for 18c. copper this fall, with the strong probability of 20c. before the end of the year.

## General Mining News

### ALASKA

#### VALDEZ

It is reported that the Tyee Smelting Co. of Ladysmith, British Columbia, is to re-start its smelting plant, and send a man to Alaska to contract for ore. This plant was shut down two years ago. The production of copper ore from Prince William Sound in Alaska is increasing. The Kennicott Mines Co. is building a mill; the Great Northern Development properties near Kuskulina will soon be ready to ship ore; the Beatson mine at Latouche is shipping steadily; and the Ellamar mine will have an output of 3000 tons per month when improvements are finished. The Fidalgo-Alaska company has 250 tons ready, and W. A. Dickey is shipping about 500 tons per month from his property on Landlock bay. News comes from Iditarod of a new find of dredging ground in the Kuskowim country, 90 miles above Bethel, opposite the Tuliesak river. It has been staked everywhere, and the gravel is only two to eight feet to bedrock, but is very wet. On Cleary creek, near Fairbanks, 35 men are working and doing fairly well.

### ARIZONA

#### COCHISE COUNTY

The Copper Queen company will probably take up its option on the claims of W. Reid, of Tucson, and also make payments on the Ramsdell, and nine claims of the Leatherwood, all being near Apache Camp. The August output of the Calumet & Arizona was 4,514,000 lb. of copper, against 4,748,000 lb. in July. In the latter mine two good discoveries of ore have been made on the 1300 and 1500-ft. levels of the Junction shaft. During the past year the Shattuck-Arizona company did 4942 ft. of development work. Important work was done on the 400 and 500-ft. levels. The carbonate of lead deposit is between the 300 and 400-ft. levels, while copper ore, high in silver, has been opened at these levels. It is proposed to add a lead furnace to the new smelting plant to be built at Douglas. During the year, ore shipments were valued at \$213,654, while development and ore shipping cost \$152,103; office expenses and taxes, \$17,118, leaving the gross profit at \$48,465.

#### GILA COUNTY

(Special Correspondence.)—The Miami Copper Co. produced in August 4322 tons of concentrate assaying close to 36% copper, which will yield about 2,900,000 lb. of fine copper. The mill recovery is reported to be 70%. There was mined during the month 97,890 tons of ore, and 4802 ft. of development work was done. About 30% of the ore came from development work, 25% from the shrinkage stopes, 35% from square-set mining next to the capping, and 10% from the stock-pile. The second 500,000-gal. mill-water storage tank has been erected, making a total capacity of 1,000,000 gal. A 600-hp. Babcock & Wilcox water-tube boiler is being installed in the powerhouse at Miami, making a total of 2400 boiler horse-power. When the installation is complete, the second 4000-cu. ft. Nordberg air-compressor will be operated. Foundations are being laid for the new steel and concrete change-house, and the construction of the new hospital, jointly with the Inspiration company, has been started. It is designed to accommodate 40 patients, and will be equipped with the most modern appliances. Two churn-drills are steadily at work developing the northeastern part of the property, and diamond-drilling continues on the 570-ft. level.

About 600 men are employed at the Inspiration Consolidated mines in underground development and construction work. Mine development is proceeding through five shafts and two adits, and two main working-shafts are being sunk. The main east shaft is over 180 ft. deep and was sunk 172 ft. in August, which is claimed to be the record for a standard 3-compartment shaft in the United

States. The main west shaft is over 350 ft. deep and was sunk 146 ft. in August. They are being sunk on contract by J. Harrington, who is working three shifts, five men on a shift, in each shaft. The company has made a contract with the U. S. Reclamation Service to take 7500 kw. of electric power from the Roosevelt dam, about 40 miles distant, and survey for the transmission line has been started. The Government does not guarantee a continuous service, however, and the company will build an emergency steam-power plant capable of generating 7500 kilowatts.

Churn-drill holes 6, 7, and 8, at the Southwestern Miami, are 925, 927, and 880 ft. deep, respectively, and are to be enlarged by under-reaming preparatory to drilling deeper, so that it will be a week or two before further depth is made in any of them. Hole No. 8 is reported to be yet in chalcocite-bearing schist, which it first cut at 720 ft. and which was reported to be of a profitable grade at 820 ft. Hole No. 7 is in silicified, iron-stained schist, and hole 6 is in schist slightly mineralized. Churn-drill hole No. 3, at the South Live Oak, is over 425 ft. deep in leached, silicified schist, the silicates and carbonates of copper no longer appearing, though some samples show small amounts of native copper. It is proposed to acquire a second churn-drilling machine and drill three more holes before the end of the year, near and in line with the one now being drilled. John Gibson, superintendent for the Globe-Ray Mining Co., of the old Independence mine, 12 miles southwest of Miami, has just completed the shipment of three cars of ore containing gold, silver, and copper to the Old Dominion smelter at Globe. The ore was carried on burros three miles to the summit of Pinal mountain, thence 9 miles by wagon to Miami, whence it was shipped 9 miles to Globe over the Arizona-Eastern railroad. It is estimated to average 7% copper, 4 oz. silver, and \$4 in gold. The mine workings are badly caved and mining has been discontinued.

W. D. Fisk and Henry Snell have taken a lease on the Black Warrior mine near Miami, and will start work immediately. The Warrior has been a famous producer of copper silicate ore, averaging over 10% copper, and was last worked by the Warrior Development Co., a Hovland-Smith corporation. Ore is exposed on the fifth or lowest level. Mr. Fisk promoted a deal whereby the Magna Copper Co. acquired the now famous Queen mine at Superior, and Mr. Snell is a mining engineer with long experience in this district. The Copper Hill shaft at the Arizona Commercial is now completely retimbered and enlarged to three compartments, from the collar down to the fourth level, where a pump has been erected, and is being operated by compressed air from the Old Dominion powerhouse. The shaft and workings below that level are now being unwatered, preparatory to retimbering and enlarging the shaft below the 400-ft. point. At the Iron Cap mine, on Copper hill, the drift east from the Williams shaft on the 650-ft. level has for the last 20 ft. been in a shoot of ore about 4 ft. wide and is reported to average 8% copper and 50% iron. A car is being loaded preparatory to shipping to the Old Dominion smelter at Globe.

Globe, September 5.

### CALIFORNIA

#### CALAVERAS COUNTY

The Calaveras Copper Co.'s smelter is nearly finished and will be started as soon as fuel oil can be delivered. The mill is temporarily shut down. At present shipments of ore are being sent to the Kennett smelter. The railroad survey from Chinese Camp has been completed, and a line can be constructed at low cost.

#### MODOC COUNTY

(Special Correspondence.)—It is said that the Modoc Mines Co. is contemplating sinking its 75-ft. shaft to a depth of 500 ft., according to apparently authentic statements. Three feet of pay-ore has been opened so far.

The company is composed of Chicago people, headed by William Wrigley, Jr. L. H. Patrick is manager. The 10 stamps of the Consolidated mill are crushing ore from the Sugar Pine claim. It is claimed that the extraction has been increased from about 47 to over 65% by alterations to the plant. It is expected to increase the efficiency of the mill by a few minor changes. R. R. Binns is in charge of the plant. Development continues in the Mountain View and Sugar Pine claims, and results are said to be encouraging. About 30 men are working. A. J. Cummings is manager. The Spearmint Gold Mining Co. has secured the Lucky Dutchman lease on the Yellow Jacket. It is stated the consideration is on the basis of part cash and part stock in the new company. The lease was originally operated by Mack and Schrott, and ranks among the best in the district. The Spearmint people also con-

BIG FOUR MINE, HIGH GRADE.

trol the Spearmint claim and Yukon group. A recent run on low-grade ore was made by the Big Four mill. The shipment averaged about \$8 per ton and it is said that the extraction was 75%. The ore regularly going to the stamps from Big Four workings ranges from \$25 to \$40 per ton. Several finds have been recently reported by lessees, but all of these were made near the surface. Most of the companies are making preparations for the winter season, which sets in early here.

Ft. Bidwell, September 6.

#### SIERRA COUNTY

Work has been stopped for the winter by Manuel and Cadman on their gravel claim south of American hill.

#### SISKIYOU COUNTY

(Special Correspondence.)—William Werst and G. W. Nickerson are developing the Sugar Hill quartz claims near Callahan. The main 120-ft. adit is being extended 30 ft., and from this point a cross-cut will be driven across the vein to the old 60-ft. adit. The vein is reported to be over 90 ft. wide, assaying \$4 to \$8 per ton. The owners intend to erect a crusher and cyanide plant next spring. The same men own the Sugar Hill placer property on Fox creek. Derricks and pipe-lines have been placed in position and everything is in readiness for two giants to operate with the early rains. It is rumored that negotiations are pending for the transfer of the Beaudry hydraulic mines to a syndicate of San Francisco, Oakland, and New York capitalists. The price involved is said to exceed \$200,000. The property embraces about 3000 acres and was located about 50 years ago. It has been intermittently operated of late. Equipment includes two complete placer-mining plants. The Shasta Mining Co. is developing a massive orebody in its property five miles southwest of Callahan. In places the lode is said to be 100 ft. wide, worth about \$5 per ton. A new adit is being driven 175 ft. below the old levels. James McKeene is superintendent. The Foster mine continues to produce 15 tons per day. Arrangements are being made to increase the working force, as conditions are said to be par-

ticularly encouraging. The vein ranges from three to five feet wide, and is worth about \$20 per ton. The mine lies in the Trail creek region. Most of the hydraulic mining companies are busily preparing for the winter season. The water has been low during the past few weeks, and save in favored localities, little placer mining is going on. Yreka, September 7.

#### TRINITY COUNTY

The Trinity Dredging Co.'s dredge, costing \$125,000, was started on the river five miles above Lewiston, last Sunday. This work has been under way for about two years. Chico people are much interested in the undertaking.

#### COLORADO

##### CLEAR CREEK COUNTY

(Special Correspondence.)—A shipment of 50 tons of ore, averaging \$40 per ton, was made this week from the Boston mine to the Linn mill, and as a result the Kelly mill will be started next week. Work has been resumed on the Lake property on Lincoln mountain, W. Aldred having been awarded a contract to drive 50 ft. The old Shively mine on Brown mountain is again being developed. The shaft will be sunk 100 ft. to connect with the adit-level. On an average, two cars of heavy lead ore are being shipped each week to the Salida smelter from the Santiago mine in East Argentine, the average grade of the product being \$60 per ton. Brammer and party, lessees at the Gambetta mine, started a 100-ton shipment of zinc ore this week which will be treated at the Mineral Chief mill. Ramonde and party, lessees at the Seven-Thirty mine, have uncovered an 8-in. vein of silver ore assaying 250 oz. per ton. Shipments have been started. Work has been resumed on the Hidden Treasure mine in East Argentine, owned by Carl Johnson. The Geneva property, on Alpine mountain, is receiving attention. A small vein of \$90 ore is showing. A 3-in. streak of glance assaying high in silver has been uncovered in the Harris mine near the top of Argentine pass.

Georgetown, September 4.

##### GILPIN COUNTY

Drifts are out 100 and 132 ft. respectively, east and west, from the 400-ft. level of the Castle Rock. On the latter drift there is 6 in. of smelting ore, and 36 in. of mill ore, assaying 1.2 oz. gold, 6.6 oz. silver, and 20% of lead. On the east side the lode is 12 in. wide. On the 1300-ft. east level of the Topeka, an ore-shoot has been opened 200 ft., for 48-in. width, worth \$10 per ton. Water is receding in the Phoenix-Burroughs group at the rate of 9 in. daily. The Chase mine shipped, during August, 41 tons of ore for net returns of \$1068. Another lot from the 600-ft. level is ready. The Pittsburg mine made five shipments. A machine is working on the 1000-ft. level, and two electric pumps are lifting 60,000 gal. of water daily.

##### LAKE COUNTY (LEADVILLE)

Shipments for the month of August amounted to several thousand tons more than in July. The Western Mining Co. hoisted about 12,000 tons, while there were increases from the Yak, Iron Silver, and Colonel Sellers. L. F. Miller, professor at the Golden School of Mines, has been in Leadville observing work in the mines, mills, and smelters, in order to arrange his lectures in a practical way. He has already visited Pueblo, Salida, Florence, and Breckenridge, and will next visit other important centres.

##### OURAY COUNTY

(Special Correspondence.)—During July the mill at the Wanakah mine worked 29.5 days and treated 1246 tons of ore with an extraction of 91%. The net value of the concentrate was \$19,472, and of 213 tons of crude ore shipped, \$4551, making a total of \$24,024. Operating expenses were \$7287, leaving operating profit at \$16,736. Development covered 225 ft. during the month.

Ouray, September 7.

There are 90 men working at the Revenue mine. Low-

grade ore has been milled in the past, but better ore is expected to be treated. Work at the Sweepstakes is being pushed as fast as possible to be ready for winter. The Telluride Power Co. is erecting poles for the transmission line. California people have purchased the Humboldt, and \$60,000 will be spent in general work. The Red Mountain Railroad, Mining & Smelting Co., owning 100 claims, which has been in the hands of a receiver for a year, was sold for \$175,000 to J. F. Thompson. At the Congress mine, once worked by T. F. Walsh, F. C. Goudy and H. B. Maris have cut six feet of ore assaying 30% copper, on the sixth level, or 410 ft. below the surface. Work is progressing with machines on two shifts. A raise will be driven to connect with upper workings, and regular shipments made.

#### TELLER COUNTY (CRIPPLE CREEK)

Water has been reached in the Mary McKinney mine at 118 ft. below No. 9 level, and a pump is being fitted to allow further sinking. During August 40 cars of ore were shipped, 34 from the company averaging \$35 per ton. On No. 9 level ore has been opened for 600 ft. in length, and nine machines are working. From the Elkton mine 3000 tons was shipped worth \$50,000; while the C. K. & N. sent out 25 cars worth \$20 per ton; the Victor mine, 35 cars of medium-grade ore; 25 cars of \$20 ore from the Ajax on Battle mountain; 75 cars of \$25 ore from the Granite; and 20 cars from the Jerry Johnston. There are 25 sets of lessees at the Granite, employing 170 men, and 37 machine-drills are at work on the property. Lessees on block 239 of the Stratton estate have cut rich ore at 150-ft. depth. One ton was settled at 44 oz., while another lot brought 72 oz. per ton. One carload recently averaged 2½ oz. per ton. A syndicate of New York and foreign capitalists has bought 400,000 shares in El Paso company.

#### IDAHO

##### COEUR D'ALENE

(Special Correspondence.)—Notwithstanding that he was blocked in his effort to make an amendment to the article of incorporation which would permit the purchase of stock in other companies and disposing of stock, F. A. Heinze is satisfied with the result of the annual meeting of the Stewart company. The judge, before whom the receivership question is to be heard, stopped Heinze's efforts in this direction. It is understood that W. O. Allison, of New York, will become president, and M. W. Bacon will continue as secretary and general manager. The auditor, engaged by E. J. Carter to examine the company's books, may be able to make a statement in about 30 days. The company's earnings for July were \$49,350, and net profits \$43,600.

Wardner, September 5.

#### MICHIGAN

##### HOUGHTON COUNTY

Shipments from No. 1 shaft of the Allouez mine average about 800 tons per day. Stopping is being done from levels 9 to 13; and 25 machines are working from levels 8 to 17. The Osceola is hoisting 500 tons per day from No. 4 Kearns shaft. The cross-cut on level 34, at the Hancock, is in ore 640 ft., the last 130 ft. carrying copper. The shaft is down 3860 ft. in trap-rock. At the Franklin, underground workings are capable of producing 1200 tons of ore per day. No. 1 and 3 shafts are to be connected at level 23, the latter now being down to level 17, and a drift is to be started from level 23 of No. 1 shaft to the latter. It is reported that the Calumet & Hecla company has decided to erect an electrolytic plant, in connection with the smelting works at Hubbell. The building will be about 150 by 250 ft., and should be finished early in 1913.

For August the following outputs of copper are published: Baltic, 1,970,000 lb.; Champion, 2,196,000 lb.; Tri-Mountain, 950,000 lb.; Franklin, 414,000 lb.; Mohawk, 1,251,000, and Wolverine, 930,000 lb. When present plans are carried out there will be 18 tube-mills for the Cham-

pion, 15 for the Baltic, and 12 for the Tri-Mountain. These mills will be fed with certain tailing which contains copper that cannot be profitably extracted by present methods. Wilfley tables will deal with the tube-mill product. The mills will be driven by motors, which derive their power from a 2000-hp. turbo-generator driven by exhaust steam from the stamps at the Baltic mill.

#### MISSOURI

##### JASPER COUNTY

The trend of zinc ore prices was downward during August, starting with \$60, the month closed at \$56 per ton for best grades of blende. Calamine prices did not vary so much, the average for the month being \$30.41. During five weeks a total of 27,732 tons of blende was shipped, and 2262 tons of calamine. Shortage of cars has been felt to some extent. Lead ores shipped averaged 822 tons per week.

#### MONTANA

##### CASCADE COUNTY

Montana coal miners and operators are in conference at Great Falls, and will sign a working agreement for the next two years. There are no signs of changes in the wage scale or any serious differences. Local capital has been organized to drill for oil under the town of Great Falls, and plant has been ordered.

##### SILVERBOW COUNTY

(Special Correspondence.)—Production of the Anaconda company for the past two months has been lower than usual, owing to improvements at the Washoe smelter. No. 1 section has been completed, and the September output should be 27,000,000 lb. of copper, compared with 24,800,000 lb. for July and August. North Butte production will not be increased, but there may be an increase from the Tuolumne. The East Butte continues with a yield of about 1,125,000 lb. The St. Louis company will erect a cyanide plant of 1100-ton capacity. This property is situated in the same district as the Piegan-Gloster mine, recently bought by the Barnes-King company, and includes the old Drum Lummond mine. There is renewed activity in the district, and all companies have made an arrangement with the Missouri River Power Co. to use electric power from its plant.

Butte, September 6.

#### NEVADA

##### ESMERALDA COUNTY

(Special Correspondence.)—The estimated production, in August, for the Goldfield Consolidated company is 32,480 tons yielding bullion worth \$426,000. Operating expenses were \$195,000, leaving net profit at \$231,000. At the meeting of the board of directors of the company, held at Reno on September 3, the regular quarterly dividend of 30c. per share was declared, payable October 31, to stockholders who are of record on September 30.

Goldfield, September 5.

At Goldfield, development of the Blue Bull, Booth, Combination Fraction, and Sandstorm-Kendall mines is under the supervision of K. M. Simpson. Enlarging and re-timbering the old main shaft of the first-named has been finished, and sinking is under way to 700-ft. depth. From this point cross-cuts will be driven to explore the Blue Bull, and the eastern half of the Victor claim of the C. O. D. Consolidated. The shaft of the Sandstorm-Kendall is down 500 ft., and opening out will be started from here. The debt of the property has been reduced to \$35,000, and cash on hand at July 31 totaled \$8136. Chicago capitalists are to sink the shaft 1500 ft. deep at the Silver Pick. It is now down 350 ft., is in good condition, and fairly well equipped. Lodes exposed by the old lessees on the 250 and 350-ft. levels, averaged \$16 per ton.

##### LYON COUNTY

The Nevada-Douglas company has finished sampling the Bluestone mine, and results are satisfactory. The price put on this property is \$1,500,000, but there is a large

quantity of 3% copper ore opened. The Thompson smelter is running one furnace at present, while the other is being enlarged by 60 in., and should soon be started, when the first one will be enlarged by 120 in. in length, giving the whole plant a daily capacity of about 1900 tons. A number of small mines along the Southern Pacific line will soon be shipping ore to the smelter.

#### NYE COUNTY

During August the Tonopah Extension mill treated 4767 tons of ore for bullion valued at \$64,800; 878 ft. of development was done in the mine, and the new main shaft sunk to 545-ft. depth. The condition of the mine is highly satisfactory. At the Montana-Tonopah, 4808 tons were

MONTANA-TONOPAH MILL.

treated yielding 34.5 tons of concentrate, and 56 bars of bullion shipped. This is a record production to date. The West End Consolidated treated 3650 tons, but details are not yet published. The mine hoist is to be increased from 75 to 100 hp., and the compressor plant of 10-drill capacity will be added to by another of 5-drill size. The cross-cut from the 600-ft. level is out 50 ft. to the lode; and the station is being enlarged. Last week the Belmont shipped 68 bars of bullion weighing 118,372 oz., to the Selby works, at San Francisco. The mill is now treating 500 tons daily. A 25c. dividend has been declared, amounting to \$375,000, making the total to date \$3,593,000. On its 970-ft. level, the Tonopah Merger has cut ore in a cross-cut 60 ft. from the shaft. The new electric hoist will be at work next week, and also the new two-stage, 100-hp. compressor. The MacNamara sent out bullion valued at \$17,000, being the result of 19 days' run of the mill.

#### STOREY COUNTY

An inspection of the pumping situation at the Comstock has been made by members of the Pumping Association from San Francisco. They went down to the present water-level at 2150 ft. in the Ward shaft, and then saw the temporary pumping plant at the C. & C. shaft. The pump and motor are doing good work. Eventually there will be three pumps in the sump of the shaft, and they will be lowered as it is cleaned out to the 2500-ft. level, when opening out will be started from that point, with permanent gear. The general situation at the north end of the lode is held to be more favorable, especially as co-operation is assured along the line.

### UTAH

#### JUAB COUNTY

A mill is to be erected for the Knight mines in the Tintic district, and will be large enough to deal with ore from other mines. It will have a capacity of 100 tons and will cost \$35,000; but it is intended to increase the plant to 500-ton capacity. This will enable low-grade ores to be treated locally, instead of going to the smelters. The Iron Blossom mine will hold back its low-grade ore on this account. The Opohongo mine sent out 24 cars of ore during

August. On the 400, 500, and 600-ft. levels there is plenty of ore averaging 3 to 12% copper, \$2 gold, and 12 to 15 oz. silver per ton.

#### SALT LAKE COUNTY

(Special Correspondence.)—Close relationship between the Utah Copper Co. and one of the principal consumers of the red metal, the General Electric Co., is shown in a recent deal in which the two interests are closely associated. Hayden, Stone & Co., bankers for the Utah Copper, have joined with General Electric interests in the purchase of control of the Telluride Power Co., and the new control is planning extensions and developments throughout the entire intermountain region. One of the possible results of this transaction is the electrifying of the Bingham & Garfield railroad and the supplanting of steam by electricity in the shovel work at the mine in Bingham. Furthermore, the Utah Copper Co. has an expensive steam-plant at Garfield generating electricity for the Magna mill, and the prospects are that this will be abandoned for electric power, which has always been used at the Arthur plant. As a preliminary step toward the adopting of electricity at the mine, one of the steam-shovels has been equipped with a motor and is being operated by this power instead of by steam. Thorough tests will be made of the two methods, and if the new way is found satisfactory, the electrification of the entire equipment will follow. The steam-plant at the Magna mill was erected when the Utah Copper Co. could not agree with the Telluride Power Co. as to rates, and this has always been the foundation for criticism by opponents of the present management. It was claimed that the cost of generating power by steam was higher than the rates offered by the Telluride Power Co. Now the Utah Copper interests and associates have bought control of the power company and can fix their own rates.

That the market in Salt Lake City for mining shares is 'not dead but sleeping' is shown by the response to the call for subscriptions to the Alaska Gold Mines Co. Immediately after the public was invited to subscribe, Salt Lake City offered to take over 200,000 shares at \$10 per share, or more than \$2,000,000 of the stock. Great was the disappointment, and in some cases anger, of the Salt Lake people when word was received from Hayden, Stone & Co. to the effect that 'insiders' would take the entire original offering, and that the public would have to pay a premium to get in. Salt Lake people followed D. C. Jackling into Utah Copper, Nevada Consolidated, Chino, and Ray Consolidated, and there is something of an uproar over the failure to get into Alaska Gold Mines, which is recommended by Mr. Jackling and A. F. Holden, both Salt Lake men.

Optimistic reports are being given out in regard to Ohio Copper Co. It is stated that the mill recently has been handling 2700 to 2750 tons per day and is steadily improving. This, however, means an occasional spurt, and does not as yet represent steady production, the average being nearer 2000 tons per day. The second payment on stock in the reorganization is due September 16. When this is paid the company hopes to be clear of floating debt and to have about \$350,000 in the treasury for working capital. Salt Lake shareholders are generally anxious to eliminate the Heinze interest, but they are not very hopeful on that score at present. W. G. Sharp, A. F. Holden, and other officials of the United States S. R. & M. Co. have recently made an inspection of the company's new coal properties in Utah. They predict that early next year the properties will be producing at the rate of over 1,000,000 tons of coal per year.

Salt Lake, September 5.

#### SUMMIT COUNTY

The mines in the Park City district shipped 201 cars, or 7020 tons of ore during August, of which the Silver King contributed 2474 tons, the Daly-West 2226, and the Daly Judge 1523. In its summary of this district, the U. S. Geological Survey report shows that it is situated at an eleva-

tion of 7200 ft., in the Wasatch range, 25 miles from Salt Lake City. The district was discovered in 1863, and has since produced about 100,000,000 oz. of silver and 300,000 tons of lead, beside much gold, copper, and zinc, production of the last named having increased rapidly of late.

## AUSTRALIA

### NEW SOUTH WALES

During July the Broken Hill Proprietary treated 18,621 tons of crude ore from the mine and 16,964 tons of dump tailing, producing 4255 tons of lead concentrate and 4670 tons of slime. The flotation plant produced 7107 tons of zinc concentrate, assaying 46.62% zinc, 6.97% lead, and 12.90 oz. of silver. The slime flotation plant yielded 1756 tons of concentrate, assaying 35.96% zinc, 16.62% lead, and 35.65 oz. of silver. The sulphuric acid plant yielded 414 tons of strong acid. At Port Pirie, three blast-furnaces were worked, and a fourth has just been blown in; also three Ropp roasters and five Dwight-Lloyd machines were in operation. The Hegeler roaster is doing good work. Six zinc-distillation furnaces were under fire for the month. The refinery produced the following products:

Silver from company's ores.....	128,564 fine oz.
Silver from purchased ores.....	217,318 fine oz.
Lead from company's ores.....	2,160 tons
Lead from purchased ores.....	5,018 tons
Antimonial lead .....	35 tons
Contents of 7107 tons of zinc concentrate:	
Silver .....	92,324 fine oz.
Lead .....	495 tons
Zinc .....	3,313 tons

The capital of the company has been increased to pay for the iron and steel works to be erected. Block 10 mill, at Broken Hill, treated 7674 tons of ore, assaying 11.5 oz. silver, 12.7% lead, and 14.5% zinc, for 1039 tons of concentrate worth 38 oz. silver, 64.7% lead, and 6.9% zinc. The Sulphide Corporation's central mill treated 17,446 tons of ore for 2887 tons of lead and 5247 tons of zinc concentrate. The Cockle Creek works yielded 847 tons of lead, containing 3785 oz. gold and 79,959 oz. silver. The Amalgamated Zinc Co. (Da Bavay's) flotation plant dealt with 45,280 tons of tailing, which produced 11,881 tons of zinc concentrate assaying 48.8% zinc, 6.6% lead, and 9.6 oz. silver. The estimated value from all sources was \$170,000, and profit \$64,000.

### QUEENSLAND

During July the Mt. Morgan smelters treated 32,116 tons of ore yielding 847 tons refined copper and 9907 oz. gold. The gold reduction works (chlorinating plant) yielded 1285 oz. gold. The estimated value of the whole output was \$489,000.

### TASMANIA

At the Mt. Lyell works during July, 22,432 tons of ore was smelted with a yield of 432 tons of blister copper, containing 427 tons copper, 29,685 oz. silver, and 576 oz. gold. The Briseis Tin Mining Co. removed 46,000 cu. yd. of overburden at the Ringarooma, sluiced 4500 cu. yd. of drift from there; and 21,000 cu. yd. of drift and overburden from the Briseis, with a yield of 45 tons of black tin. At its Wallace property in Victoria, 118,000 cu. yd. was dredged, yielding 865 oz. of gold.

### KOREA

The June output of the Oriental Consolidated was valued at \$140,255, from 28,483 tons of ore treated. The new cyanide plant at Taracol is working well, and treated 2228 tons of concentrate for bullion worth \$50,237, the extraction being 90%. Screen analyses show that 90% of the ground material will pass a 200-mesh screen. The circulating pumps for the Merrill precipitation presses have been speeded up, in order to get a more complete contact. A. E. Drucker expects 94% extraction when all is in proper order; if not, the time of agitation will be lengthened. Erection of the Chosen mill has been suspended pending further work underground.

## MEXICO

### MEXICO

For the year ended June 30, the Mexico Mines of El Oro treated 142,844 tons of ore averaging \$9.02 in gold, and 6.1 oz. of silver per ton, from which bullion totaling \$1,555,095 was recovered. The extraction averaged 87.30% of the gross contents. Working costs, including 91c. per ton for development, 48c. for state and Federal taxes, and over \$10,000 for repairs and renewals, totaled \$4.37 per ton. Four dividends, amounting to \$710,000, were paid. Ore reserves now stand at 295,000 tons valued at \$11.65 per ton.

### SONORA

(Special Correspondence.)—The rebel invasion of Sonora has not been a successful campaign. The railroad is open

A FIELD OF MAGUEY, IN SONORA.

again to San Blas, and up the Yaqui as far as La Dura.

Tucson, Arizona, September 4.

The July production of the Cananea Consolidated smelter was 6,100,000 lb. of copper, and for August it will be nearly 7,000,000 lb., due to the two new converters of the Great Falls type being at work for part of the month. The Democrata smelter has been shut down temporarily. The new 250-ton capacity smelter should be at work in about 40 days. The incline shaft at the Calumet & Sonora is being widened from the surface to the 400-ft. level, to permit working another skip. Both the wet and dry mills are working one shift each.

It is reported that platinum ore in fair quantities has been discovered by A. Jahnke, four miles west of Nacozari.

### ZACATECAS

The Mezquital mines in this state have been bonded by Philadelphia people, and it is also said that the Amparo company, of the Etzatlan district, is interested.

## PHILIPPINE ISLANDS

### MANILA

The steamer *Sotolongo* brought a shipment of gold valued at ₱43,000 from the Colorado mine at Aroroy, Masbate. Of this amount ₱30,000 is from an ordinary fortnight's run, the balance being in slag, which goes to San Francisco. This mine has been a steady producer since the mill was put into commission seven or eight months ago.

### PERU

Interviewed at Lima during the latter part of August, W. F. Stevens, manager of the Ferrobamba mines, stated that development progress for the past six months had been far greater than in any similar previous period in the company's history. There has been about 8300 ft. driven in adits, beside churn-drill holes. About 9 miles west of the main camp, extensive deposits of copper and iron sulphides are being opened. Prospecting is being carried out along a range of hills which run west from Ferrobamba, about 13 miles long. As a lack of sulphide ore has been a drawback to the success of the mines, this discovery is very important, and work is being concentrated on that section.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HOWARD D. SMITH has gone East.

A. E. BARLOW is in British Columbia.

T. INOUE was in New York recently.

CHARLES KIRCHEN was down from Tonopah.

R. C. BENNER was in Ontario through August.

J. M. BELL is expected at Porcupine, Ontario.

R. B. LAMB has returned to Toronto from London.

JOHN G. KIRCHEN was in San Francisco this week.

H. C. HOOVER has taken a house in San Francisco.

W. L. FLEMMING is back in New York from Cobalt.

R. M. THOMPSON has returned to New York from Stockholm.

HOWLAND BANCROFT is examining properties in western Colorado.

J. MORGAN CLEMENTS is in the San Juan district of Colorado.

ADOLPH KNOPF is in Inyo county for the United States Geological Survey.

J. D. HUBBARD returned to California from Korea on the *Nippon Maru* this week.

F. L. GARRISON has returned to Philadelphia, but expects to come West late in September.

R. K. CLANCY, general manager at the Craig mine in Trinity county is very ill at his home in Berkeley.

C. V. GROHOVSKY, general manager for the Upper Amur G. M. Co., was in San Francisco and has gone to Nome.

YUSHIO TSUBOI and YOICHI KATSURA, of the Fujita company, have been at Butte and have gone to Utah and Colorado.

OLIVER B. FINN, general manager for the Pan-American M. & E. Co., is spending September at the property of the company in Quebec.

R. J. PROVINCES has returned to Grass Valley from Inyo county, California, where he has been in charge of the Renard Mining Co.'s mill.

NORMAN B. ROPER, formerly with the Cerro de Pasco M. Co., but now with Backus & Johnson Co., Casapalea, Peru, is visiting the United States.

WALTER J. RADFORD, elder son of W. H. RADFORD, has joined a large exploration company and is on his way to Brazil to do extensive work.

J. A. L. HENDERSON sailed from England on the *Laurentic*, August 31, for New Brunswick, Canada, where he will be engaged for about three months.

HENRY H. ARMSTEAD has finished his inspection of the properties of the Colmena M. Co., at Guanajuato and has gone to New York. He will return to Mexico in November.

## Obituary

THOMAS LANE CARTER, who died while examining the Polaris mine near Dillon, Montant, September 3, was born in Louisiana and graduated in engineering from Tulane University. He began his professional work on the staff of the Crown Deep at Johannesburg, and later went to the Robinson Central Deep. He spent some time in Central Africa in exploration, and from 1905 to 1908 was manager of the French G. mine, one of the Eckstein properties. Later he was in Nicaragua and other Central American countries, and at the time of his death was a member of the firm of Osgood, Carter & Co. of Chicago. Mr. Carter was an easy graceful writer and found time not only to contribute frequently to the literature of his profession, but to write an interesting series of sketches of life in Africa. He was one of the valued members of the staff of special correspondents of the *Mining and Scientific Press*.

## Market Reports

### LOCAL METAL PRICES

San Francisco September 12.

Antimony.....	11-11½c	Quicksilver (flask).....	42.50
Electrolytic Copper.....	18-18½c	Tin.....	50-51½c
Pig Lead.....	5.35-6.30c	Spelter.....	8-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, September 12.—Copper remains quiet but firm. There is fair domestic demand, but European buyers are still holding off. Lead is strong and advancing. Spelter firm. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Sept. 5.....	17.55	4.85	7.35	62½
" 6.....	17.55	4.85	7.38	62½

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**HIGH EXPLOSIVES.** By W. R. Quinian. 209 pp. Critchley Parker, Melbourne, 1912. For sale by the *Mining and Scientific Press*. Price \$8.

This is a posthumous volume, its author, who had spent many years in the study and manufacture of high explosives, having died shortly after the preparation of his manuscript. Though written in treatise form, it is scarcely that, being rather a collection of essays, some of them profoundly theoretical, on high explosives. During 16 years as superintendent of the California Powder Works and later (since 1900) as general manager of the Cape Explosive Works, Ltd., Mr. Quinian devoted much time to the study of the theory of high explosives, as well as to the more practical phases of their manufacture, and in this volume the amount of knowledge the reader is supposed to possess is so great that the general reader will be likely to find the plane of the discussion above his head. But to the members of the chemical engineering profession who specialize in the field of high explosives this little volume will be of the greatest interest.

**MODERN COPPER SMELTING.** By Donald A. Levy. 243 pp.; ill. Chas. Griffin & Sons, London, 1912. For sale by the *Mining and Scientific Press*. Price \$3.50.

In one of Stockton's delightful stories a young woman continually discoursed upon the desirability of each person cultivating his own individuality, and the results of the too literal application of the doctrine serve to contribute to the humor of the tale. A desire for individuality must have inspired Mr. Levy in his appropriation of a title used by Peters many years ago, and a similar characteristic appears in his rendering of the names of persons and places and of titles of papers. The volume is so amateurish that it would be hardly worth while to attempt a review of it, were it not that, like the curate's egg, it is quite good in places. The general outline and method of treatment is good, and much of the data included is recent, but it is unfortunate that the execution is so poor; many of the statements are inaccurate, and others give inaccurate and misleading impressions because only incompletely stated (and apparently incompletely understood) by the author. Mr. Levy is evidently quite unfamiliar with the mineralogy of the ores of copper and repeats the common misstatement that "chalcopyrite is by far the most widely distributed ore of copper and furnishes the greater proportion of the world's supply," and is evidently of the impression that the ore of the Butte district is chalcopyrite. As is well known, chalcopyrite is quite subordinate at Butte, the copper occurring in the form of chalcocite and enargite. Chalcocite, to which the author attaches also Nicol's old and unused name of redruthite, he says "is much less important," as indeed it would appear to one unaware that about three-fourths of the production of the Butte district and a large part of the production of Utah, Arizona, and Nevada is derived from that mineral, while enargite and chrysocolla are not even mentioned. A similar lack of complete information is exhibited by the succeeding chapters, and in the descriptions of equipment and practice the author does not clearly distinguish between what is antiquated or obsolete and what has been recently developed. A totally disproportionate amount of space has been accorded to Anaconda smelting practice which, though excellently adapted to Anaconda conditions, can scarcely be considered to cover the whole field of copper metallurgy. The chapter on the converting of copper matte is a compilation of recent articles on the subject, so badly compiled as to be of little value. The good features of the volume indicate that in five or ten years from now Mr. Levy might produce

an excellent treatise; it is to be regretted that he did not wait that long before issuing his first edition.

T. T. R.

**THE HYDROMETALLURGY OF COPPER.** By Wm. E. Greenawalt. 494 pp.; ill. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$5 net.

There can be little doubt that one of the most important metallurgical developments of the near future will be the use of wet methods for the treatment of low-grade copper ores and tailing. Such methods are attracting general attention, and Mr. Greenawalt's book is correspondingly timely. The author is well known to the metallurgical profession by his work on roasting and chlorination, and is able therefore to add much material from his private notes to what would otherwise be largely a compilation of existing material. Unfortunately, he displays throughout the common fault of inexperienced authors in introducing material that has no apparent bearing on the topic under discussion, thereby causing the reader to lose whatever thread of argument may exist. Thus chapter III is largely composed of descriptions of experiments on the roasting of the gold telluride ores of the Cripple Creek district; an interesting subject, but one which has no visible bearing on the hydrometallurgy of copper. The style of the author is peculiarly obscure, both as to single sentences and whole paragraphs; thus the chapter on fuel conveys to any ordinary mind that the best practice in roasting consists of the use of bituminous fuel in gas-producers, burning the resulting gas in the roasting-furnace. This will come as a surprise to most metallurgists, as will the suggestion that, "If wood has to be transported any considerable distance, it might be profitable to convert it into charcoal at the forests and then burn it in the roasting-furnace, after having converted it into producer-gas." To still be able to burn wood after having converted it into gas is certainly a feat that should produce high fuel economy. Looseness of expression frequently leads to erroneous statements, as that on page 82 that the current in a thermocouple is proportionate to the heat applied. It is too much, of course, to expect any metallurgist to spell the name of McDougall correctly, but a higher average of correct renderings of the other proper names throughout the book ought not to present unusual difficulty. Indeed, to find a reference to the "Bayone plant of the Oxford Copper Co." in a book published in New York City, makes one wonder if proof-readers are no longer necessary. Typographical errors in a journal have some excuse, but the more leisurely preparation of a book ought to eliminate the more obvious ones, at least. The general principles of metallurgical operations have already been adequately treated in any one of several texts that are generally available, and Mr. Greenawalt might well have omitted Part I of his book and devoted a correspondingly greater amount of attention to the study of hydrometallurgical processes for the extraction of copper, in Part II. This part is good and will be of much service to all who are interested in the hydrometallurgy of copper but have neither time nor facilities for going through the scattered literature of the subject. While the subject is in so uncrystallized a stage as at present, it would have been well to make the treatment as comprehensive as possible, and at least brief references to the Mackay, Braxeres, and other processes might have been made, though the number already covered is very great. Not only the various processes for the extraction of copper are given, but also the extraction of precious metals from copper ores, the treatment of zinciferous ores, of nickel ores, and the precipitation of copper from mine waters. The concluding chapters deal with the refining of copper precipitate, making of bluestone, apparatus and appliances, power data, and economic considerations. The second part of the volume is as admirable as the first part is faulty, and readers who begin at the middle of the book will be most grateful to Mr. Greenawalt for his timely treatise.

T. T. R.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice or mining, milling, and smelting.

**VENEZUELA** provides in its present mining code that one-third of the net proceeds of a mine should go to the owner of the surface ground; this has deterred investment of foreign capital in development of mines. At the suggestion of the Attorney-General, the Supreme Court of Cassation has rendered a decision, in which articles 40 and 42 of the Mining Code, the ones containing the above provisions, are declared to conflict with the National Constitution. It is expected that this decision will awaken more interest in mining.

**FLUORSPAR** is used in the manufacture of glass and enameled and sanitary ware, the electrolytic refining of antimony and lead, the production of aluminum, the manufacture of hydrofluoric acid, and in the iron and steel industries, where it is used as a flux in blast-furnaces and in basic open-hearth steel furnaces. It is estimated that about 80% of the American fluorspar output, mainly in the form of gravel spar, is consumed in the manufacture of basic open hearth steel. The use of fluorspar is increasing in practically all these industries.

**QUARTZ** occurs in many different forms, such as sand, tripoli, sandstone, and quartzite. In some forms, such as rose and smoky quartz and amethystine quartz, it has a gem value. Massive crystalline quartz and flint are used in the manufacture of pottery, paints, and scouring soap and as wood filler. Considerable quantities of ground quartz are used in the manufacture of paint, in some cases as much as one-third to the total pigment consisting of this material. Quartz crushed and graded to various sizes is used in the manufacture of sandpaper, sand belts, as a scouring agent with sand-blast apparatus, etc. Blocks of massive quartz and quartzite are used in the chemical industry and as a flux in copper smelting. Ground quartz is also used in filters and in tooth powders and by dentists as a detergent.

**MICA** is used principally at present in the manufacture of electric apparatus. In the early days of the industry in this country the chief demand for mica was for use in glazing, principally in stoves. This is now one of the less important uses. The value of good sheet mica that is suitable for glazing is greater than that of the material suitable for electric purposes. The demand for glazing mica is insufficient to use all the sheet mica produced, so only the best quality and larger sheets are used for this purpose. 'Micanite,' or built-up mica board, for the manufacture of which much smaller sheets can be used, is an amply good substitute for large sheet-mica in much electric work. Waste and scrap mica when ground have a wide application in the manufacture of wall-paper, lubricants, and electric insulating material.

**DRILLING** contests of an unusual character took place at Calumet on August 24. Eleven mine captains acted as judges, and prizes were from \$25 to \$100. In the machine contests eleven rules governed the rigging of machines and drilling. The Ahmeek team won, taking only 1.42 minutes to assemble the machine, and 3.42 minutes covering the two minutes' drilling and assembling. The Calumet & Hecla Amygdaloid team took 3.43½ minutes, and a team from the Wolverine finished in 3.47 minutes. Twenty teams entered, and an Ingersoll-Rand machine was used. Seventeen men entered the one-man contest, which was won by Calumet & Hecla in 4.33½ minutes, Alluez second, in 4.42½; and Wolverine third, in 4.45 minutes. In the contest between a hammer and drill team, and a one-man 'butterfly' machine, drilling in granite for 15 minutes, the former drilled 49 in., and the latter 60 in., with one minute to spare.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### OIL PIPE-LINE—DAMAGE FROM LEAK

Where an oil company so defectively constructed its pipe-line that oil leaked therefrom, and mingling with the percolating waters on adjoining land, rendered a well thereon unfit for use, the oil company is liable to the owner of the well for the damages he has suffered during the time he was deprived of its use and resulting from such deprivation.

*Texas Co. v. Giddings*, (Texas) 148 Southwestern, 1142. May 25, 1912.

### IRON MINES—FLOWAGE OF ADJOINING LANDS

Where defendants were operating an iron mine, and so negligently constructed, arranged, and allowed the embankment about the slush pond into which the refuse from the iron washers passed to remain of insufficient height and thickness, that the embankment gave way and plaintiff's adjoining land was flooded, defendants were held liable for damages measured by the difference in the value of plaintiff's land just before and just after the injury.

*Gloss-Sheffield Steel & Iron Co. v. McCulloch*, (Alabama) 59 Southern, 210. June 4, 1912.

### COAL MINE LEASE—CONSTRUCTION

Where, under a coal mining lease, the lessee agreed to pay a fixed minimum royalty if the minimum tonnage were not mined by him each year, provided that the charge should not apply if the lessee were prevented from mining by reason of strikes, lockouts, fires, floods, or any other cause beyond the control of the lessee, the fact that the mine became so dangerous to operate that the lessee could not secure miners willing to undertake the risk, would not excuse him from payment of the minimum royalty.

*New York Coal Co. v. New Pittsburg Coal Co.*, (Ohio) 99 Northeastern, 198. June 5, 1912.

### PATENT CONCLUSIVE AS TO COLLATERAL ATTACK

Where a non-mineral patent has been issued to a railroad company, and the land was subsequently alleged to be mineral in character in a petition for the institution of a suit to cancel by the United States, it was held that the land department has no jurisdiction to inquire into and determine the rights of one claiming adversely to the patentee. Any proceeding instituted after patent by the Department being solely for its own information to determine whether proper ground exists for a suit to cancel the patent, one claiming adversely to the patentee is not entitled to be heard in such a proceeding. Such a suit will not be advised by the Land Department unless it appears that some interest of the Government, or of some party to whom the Government is under obligation, has suffered by the wrongful issuance.

*Heirs of C. H. Creeciat* (Land Department), 40 Land Decisions, 623. March 21, 1912.

### OIL PLACER WITHIN NATIONAL PARK—INSUFFICIENT DISCOVERY

A placer mining location within the limits of lands withdrawn from the Glacier National Park, upon which no discovery had been made at the date of the act of May 11, 1910, creating said park, was invalid and did not except the land covered thereby from the operation of the act. A small seepage of oil upon the surface of a spring of water, and a slight flow of natural gas, insufficient for commercial purposes and without value, from a drilled well, which failed to develop oil, are not sufficient to constitute such a discovery of oil as would support a placer location. Permission to prosecute further development work with the object of making a discovery denied. The claims being invalid at the date of the act creating the park, the lands embraced therein became a part of the park, and a later discovery of oil would be of no avail.

*Butte Oil Co.*, (Land Department) 40 Land Decisions, 602. March 25, 1912.

## EDITORIAL

NATAL is worried by the high cost of living, and commodity prices in Durban are said to have increased 25 per cent in the last few years. "Oh for a lodge in some vast wilderness."

COINAGE of gold has been resumed at the mint at Medellin, Colombia. The adjacent region is one that has been productive of gold for many years by native methods, and the development of dredging operations by American and French capital is now well under way.

AMONG our new exchanges is *The Nation's Business*, published in the city of Washington by the Chamber of Commerce of the United States. Its opportunity to furnish a comprehensive survey of the constructive progress of the nation is a great one. It is to be hoped that it will be devoted to "progress and organized promotion," rather than 'big business.'

TROUBLE is on foot in the affairs of the Crown Chartered Gold Mining Company, of Porcupine, and a writ has been issued charging the directors with conspiracy to dispose of valuable claims belonging to the company. Of the true merits of the affair we are not informed, but the incident serves to indicate that directors do not always keep clearly before their minds the elementary conception that their true function is to serve as trustees of the interests of shareholders.

KATALLA oilfields were described by Mr. Arthur Thompson, in our issue of August 10. Since then the Amalgamated Development Company has found a flow of oil in an 850-foot well, recently drilled, 40 barrels of oil having been bailed out in one day. In another well, which has reached a depth of 80 feet, a rotary drill is being used and an increase in depth of one foot per hour obtained. The outlook is decidedly encouraging and the citizens of Katalla are properly jubilant.

WORK of the Bureau of Manufactures and the Bureau of Statistics, of the Department of Commerce and Labor, has been consolidated as the Bureau of Foreign and Domestic Commerce. In addition to the former activities of the old Bureaus, the new one will undertake investigations of the factors which enter into the cost of production of articles at home and abroad. If the investigation is made sufficiently comprehensive and is carried out by competent men a useful service will be performed.

TELEGRAPH rates in China have been materially reduced. Messages to any part of the republic are now transmitted at the rate of 5½ cents per word, and at half that rate for press messages. Messages within a province are transmitted at half the national rate. It may surprise many to learn that telegraphs extend to all parts of China, and are supplemented by the telephone in all important cities. The service, developed by the Imperial Maritime Customs, is now under Chinese supervision, and is excellently managed and well patronized.

**C**OPPER and copper manufactures imported into and exported from the United States are expected to reach a value of \$150,000,000 in 1912, almost  $2\frac{1}{2}$  times that of a decade ago. Nearly three-quarters of this sum will represent exports, the imports chiefly consist of blister, matte, and ore sent to the United States for smelting and refining. Europe furnishes the great market for American copper, Germany alone taking nearly 160 million pounds in the 9 months ended March 1912. Copper is fifth among the articles of export in the United States, being exceeded only by raw cotton, iron and steel, meat and dairy products, and breadstuffs.

**L**OW costs are easily made when no limit is set to capital account, but many a good venture has been wrecked by failing to pay a fair part of expense out of earnings. Rand companies are just now loud in their protests over the impossibility of raising additional capital and explain decreased profits as due to the resulting necessity of charging to earnings much that had formerly been paid from capital. On the other hand, the International Smelting & Refining Company, which it will be remembered has paid dividends from the start, has announced that additional construction amounting to \$2,000,000, equivalent to 20 per cent of the capitalization, will be paid for out of earnings. At the Alaska Treadwell mines the new central shaft and hoist, as all other improvements, are likewise financed out of earnings. Too great dependence upon the capital account is the easy road to "phantom profits."

**S**UBSCRIPTIONS to the land fund of the American Institute of Mining Engineers are being made by many who can afford to give but small amounts. One young engineer writes: "I have given \$10 and am prepared to repeat the subscription next year, provided most of the outside members subscribe this year. I regard this as an assessment of an extra year's dues and would rather pay a few such assessments than to have dues permanently increased to \$15." This point of view is reflected in other letters. In case the total of subscriptions and of funds made available by the proposed economies in administration does not meet the payments as they are due, an increase in dues will be necessary. We believe that a small temporary addition will be approved by the membership, provided that the time and amount be definitely stated and the funds applied only to the one purpose. In the meantime no one need hesitate to subscribe because he can not give a large sum. Not much is needed if every member will give.

**T**HE lead market is one of the most interesting in the list of metals just at the moment. Pig lead is selling at about 5 cents per pound at St. Louis; notwithstanding the duty of  $1\frac{1}{2}$  cents per pound, pig lead is selling here and abroad at about the same price. If foreign quotations are based on fundamental conditions, a further rise in lead prices may soon be expected, as the price abroad would be equal to about 6.35 cents here. There are several elements that go to the making of increased activity in the lead market. One of its principal uses is in paint, and while the high price of linseed oil has been an adverse factor for the past two or three years, present indications are that there will be a bountiful crop of flaxseed, which will make oil paints relatively cheaper; at the same time lumber has advanced so greatly in price that its preservation by means of paint becomes much more necessary, making a larger increased consumption of lead. Evidently lead producers are about to experience a boom, and mining districts, such as Joplin, Baxter Springs, and the lead producing regions of Oklahoma, may look to see a much better market for mining properties.

**A**LONG the Mexican border the acute situation continues to affect mining adversely. It was reported this week that Mr. Walter Douglas, son of Mr. James Douglas, of the Phelps-Dodge company, had been captured by rebel forces at or near Nacozari. It was later learned that Mr. Douglas got through to Douglas safely, but had a very exciting trip from Nacozari in a motor car. While newspaper despatches have been sensational, the price level in such enterprises as Phelps-Dodge and Greene-Canea has not suffered, and evidently the private advices do not portray so serious a state of affairs as a reading of the newspapers would warrant one in believing. Notwithstanding the disturbed conditions, the Phelps-Dodge company made a new high record at the Montezuma mine in August, turning out 3,229,389 pounds of copper. The Douglas smelter made a high record of 11,270,263 pounds, this including ores from the Copper Queen, the Montezuma, and custom ores. The entire output of the Phelps-Dodge properties for the month was 13,152,552 pounds, which has never been exceeded except once, in December 1911, when the output was larger by about 40,000 pounds.

**B**OLIVIAN goldfields are a sore subject with some engineers and prospectors just now. In a private letter a prospector now in the country relates some further complications which have arisen. The prospector and his party had taken up 200 *pertenencias* on the Negos river in Caupolican, and were proceeding to develop it. Meanwhile the Bolivian Government had taken in charge a party of American miners, brought in by the misleading Ferguson letter, and sent them out with a guide to take up 10 *pertenencias* each along the Negos river in Muñecas, but the guide led them to the larger river of that name in Caupolican, where the alluvial ground is much richer. While negotiations were in progress two agents of one of the most influential men in Bolivia arrived, together with the *superfecto* of Muñecas province, the justice of the peace, and the *corregidor* of the nearest town, and a squad of soldiers, and proceeded to take possession of the Negos and adjoining rivers. The original locators had no redress, as they had not taken possession of the river, and were glad to sell their equipment to a neighboring enterprise and leave the district. With the buoyant spirit of the prospector, the writer concludes, "Our consolation is that we are now headed for God's country."

### Wet Methods of Copper Extraction

Perhaps the most confidently expected advance in the art of metallurgy is the devising of a wet method for the extraction of copper from its ores upon a large scale and at a good profit. Legions of methods have already been devised, but none which meet the governing conditions of applicability upon a large scale, and yield of a satisfactory profit. How great a demand exists for such a method can be readily realized from the fact that in Utah 4,500,000 tons of material carrying 10 pounds of copper per ton is escaping through the tailing launders of the copper concentrators, in Montana an equal amount of even richer material is similarly escaping, while in Nevada, Arizona, and other states the losses probably serve to bring the total up to 200,000,000 pounds of copper annually run to waste in the tailing from ore-dressing plants treating sulphide ores. Ore dressing is a highly developed art, but it is one that is not well adapted to extract small quantities of a valuable mineral from a large quantity of gangue unless the valuable mineral is free from the gangue and of much greater specific gravity, as in the case of gold-bearing gravel. Metallic ores are commonly intimately associated

with the gangue, the difference in specific gravity is often not great, and, most unfortunately, ores are frequently so friable as to yield, during crushing, considerable amounts of material which is in so finely divided a state as to bid defiance to all ordinary ore-dressing methods. While it may be reasonable to hope that the losses in tailing may be decreased, for example, from 10 pounds per ton to 6 pounds per ton by improvement in ore-dressing methods, there can be little doubt that the ultimate 5 or 6 pounds of copper in the tailing from the concentration of sulphide ores will forever continue to resist all efforts for its recovery by mechanical concentration.

The ease with which a part of the copper in ores can be extracted by wet methods has stimulated efforts to discover a commercial method, and in a few cases success has been attained. But, as a general statement, it is safe to say that wet methods for the extraction of copper from its ores have not yet been successfully applied on a large scale. Some of the difficulties are those common to all wet processes, others are peculiar to the treatment of copper minerals. Before the cyanide process had reached its present development the hope of ultimate success was much more slender than now. The cyanide operator has largely solved the many mechanical problems incident to the handling of crushed ore and solutions, and their separation, and the metallurgist who wishes to treat copper ores by wet methods has, therefore, an accumulated fund of experience and achievement which forms an invaluable asset. Cyanidation experience cannot be applied *en bloc*, however, for the richest silver and gold-bearing material which has been treated by cyanidation carries only 85 ounces of precious metal per ton. Treating material worth \$1.50 per ton carrying 160 ounces of metal offers a decidedly different problem from the treatment of material worth \$500 per ton and carrying 85 ounces of metal.

The chemical problems involved in solution methods for the extraction of copper are the most baffling. The tailing previously mentioned consists largely or entirely of sulphides, and no feasible method has yet been devised for the treatment of raw sulphides. The material must first be roasted, and even where this can be accomplished for less than 50 cents per ton, it forms a heavy addition to the total cost of treatment of material worth only about \$1.50 per ton. After roasting, the ore may be treated by solutions of alkaline cyanides, sulphites, sulphates, or chlorides. The alkaline cyanides have the advantage of extracting the precious metals present along with the copper, but the consumption and mechanical loss of cyanide, and the cost of the heat required in boiling out the ammoniacal copper solution has so far proved a bar to its successful use. Similarly, in the case of sulphurous acid and sulphites, the dilute solutions obtained and the difficulty in securing complete precipitation of the copper are serious disadvantages. The use of sulphuric acid or sulphates is perhaps the most promising of the chemical methods. It is not practicable here to go into the difficulties involved in the various special cases in which this method has been tried. But, speaking generally, the action of sulphuric acid on the bases other than copper present in the ore, the difficulties due to the formation of -ous and -ic compounds, the difficulty of securing complete solution and precipitation, and the whole group of problems centring around mass action, have so far prevented the profitable operation of the many processes which have been devised for the use of sulphuric acid or sulphates as a solvent for copper. The use of chlorides offers many of the same problems in accentuated form, since the other bases present are more easily attacked by chlorides than by sulphates. A mechanical difficulty of all such chemical processes not shared

by the cyanide process is the attack by solutions upon the apparatus used. Iron and steel are the common materials of construction, and chemicals which will attack copper will more vigorously attack iron. Possibly some chemical will be found that, like potassium cyanide, is more effective in dilute solutions, but so far it has been found necessary to use strong solutions which are chemically active toward the vats and pumps necessary for treatment. None of these difficulties are insuperable, but each adds to the cost of treatment and the margin for profit is perilously small.

After the copper has been taken into solution, its precipitation and subsequent conversion into marketable form is a necessary operation that cannot be performed without cost. Elsewhere in this issue reference is made to the precipitation of copper from mine water at Butte by the use of scrap iron, and its precipitation at the Besshi mine with iron and coke. Pig iron costs  $1\frac{1}{4}$  to  $1\frac{1}{2}$  cents per pound at Birmingham and Pittsburg, and its cost at a copper mine is enormously increased by freight charges. In the average case the cost of pig iron for precipitation of the copper would possibly be 4 to 6 cents per pound of copper produced, a heavy item in the cost of operation. Electrolytic precipitation offers advantages in remote places, and it is stated that it will be adopted in the leaching plant at the Braden mine, Chile. But there are many difficulties in the electrolytic precipitation of copper from dilute and often impure solutions, and a universal solution has not yet been found. The task of finding a profitable wet method is like that which faced the small boy sent to dig out a woodchuck, it must be accomplished. Able investigators are at work upon the problem in many laboratories and plants, and it is not too much to hope that a satisfactory solution will before long be found.

## Publicity and the Press

By T. A. RICKARD

Legislation recently proposed in Congress to secure publicity in regard to newspaper ownership is a step intended to check the insidious power of corporations, whereby the fountains of public opinion are polluted at their source. A clause inserted into the Post-Office Appropriation Act would require newspapers to file twice in each year a statement of circulation and the names of the managers, besides a list of the shareholders (if a company) or the name of the proprietor (if privately owned). Furthermore, it was proposed that this information should be published by the newspaper itself. These provisions were eliminated from the bill before final passage, however.

We welcome such legislation, deeming it altogether desirable that secrecy of ownership shall not be a cloak for an insidious misuse of the press. It is common knowledge that certain newspapers and magazines are owned by individuals or groups having a purpose in moulding public opinion. That purpose may be good or bad; it is well that it should be disclosed by publicity. The greater evil, however, of anonymous ownership arises from the use of newspapers by individuals or corporations for the purpose of deceiving their readers by posing as impartial critics or sincere advocates while under the control of parties interested in moulding opinion for specific business or political purposes. The time was when anonymity was the rule in journalism. Even Alexander Hamilton had to go through the form of signing his easily recognizable writings with the pseudonym of 'Pacificus' or 'Camillus'. The foremost of all editors, John Delane, maintained a policy of self-erasure that enhanced the dignity of *The Times*. Yet even the greatest of all newspapers in later days has departed from its ancient custom,

finding it advisable to publish special articles signed by men whose names offer a guarantee of peculiar fitness to enlighten the community on given subjects. In technical journalism it was ascertained long ago that it is well to publish signed articles, so that the readers may know on whose authority definite statements are made and on whose experience definite opinions are based. In some cases the editor thinks it desirable even to tell the readers something concerning a writer's special qualifications, as enhancing the value of his writing. In other words, the technical public likes to know who is 'the man behind the gun.' Similar tendencies have caused publishers to place the name of the responsible editor on the title-page of their periodicals. The 'leaders' or 'editorials' are customarily unsigned, hence the publication of the name of the man who either writes them or assumes direct responsibility for them. In technical journalism we had the example of Richard P. Rothwell, who made *The Engineering and Mining Journal* for many years the leading authority on the technology of mining. When Dr. R. W. Raymond wrote a leader, he affixed either a star or his initials, finding it advisable to dissociate himself occasionally from the views expressed by his colleague. When these two great men ceased to control the *Journal*, the names of the editor and his assistants appeared on the title-page, for I, then editor, and part-owner, considered it proper to give them credit for participation in a work that was deemed honorable and useful. Besides doing this, I introduced the custom of publishing, under the names of the editors, a list of 'Special Contributors,' that is, mining engineers, metallurgists, and geologists of proved capacity who undertook to contribute an important article at least once each year. By carrying their names on its title-page the *Journal* did these men an honor, and they in turn, by allowing their names thus to appear, were giving the *Journal* the support of their reputation as distinguished practitioners. This expression of a policy of publicity was not maintained after I ceased to be editor of *The Engineering and Mining Journal*, but it was adopted in my subsequent control of the *Mining and Scientific Press*. Since January 1906 we have given not only the names of the editors, and those of the special contributors, but it has been stated frankly who was, and is, in control of the paper. This last admission or assertion has proved useful in stultifying various rumors regarding the control of the paper by the Guggenheims, the Standard Oil, or any one of the many big business interests that exercise a preponderating influence in American mining finance. When the *Mining and Scientific Press* undergoes a change of control, the fact will be recorded on our first page, for we need no congressional legislation to induce complete frankness in this regard. We believe that it is well to make these things plain, and we have found ample reason to believe that the engineering profession likes to know who are the men behind the pulp that makes the Press, especially the one that they call, for short, the 'M. & S. P.' Further, we have never made any secret as to the identity of our shareholders. Besides the controlling owner, the shares are divided among members of the staff and the special contributors. Our share-register is, and has always been, open to anyone having a serious motive for caring to examine it.

Apart from personalities, in themselves not wholly uninteresting to our readers, it is well for all good citizens to support any enactment that operates for sincerity in journalism. At its best, journalism is a criticism of life; at its worst, it is a social scavenger. In matters of industry, of technology, and of finance, the power to mislead and misrepresent is palpable. To have no press at all is better than to have one that is subventioned or suborned.

In financial matters appertaining to mining the control of papers is a powerful agent of deception. New York and London can supply plenty of examples. The maintenance of papers as the organs of 'houses' or syndicates has been an easy means of playing upon the share-market and upon the gullibility of the general public. It has been a fruitful method of bolstering iniquitous schemes and of blackmailing some that were good but weakly supported. In matters of the purse it is absolutely essential that the critic—that is, the editor—should stand aside from the game. He should know something about it, either by observation or past experience, but he must not be trammelled by participation. It is human to err; it is peculiarly human to be prejudiced through self-interest. Reliable comment requires mental detachment. No assurance of such detachment is possible unless it is known, to all whom it may concern, who is the editor and who is the controlling owner. Publicity is the policeman of chicanery. Frankness is the gauge of sincerity. The ways that are dark and the tricks that are vain in finance and in the business of mining will prosper least when most exposed to the light of free criticism. The pen is indeed mightier than the sword, but too often it is but the sword of a mercenary open for hire by anybody able to pay the price. It must be as the sword of the man who fights only for a cause he loves and only for a commander he trusts. In practice this is best consummated by the editor being also the owner. Undoubtedly when this identity obtains it affords a guarantee of direct responsibility. If this ideal condition cannot be created, then it is well for the publisher to be wholly detached from the matters on which the editor has to comment, for this gives a reasonable probability that the editor will be accorded a free hand to express himself in print. When papers are owned by financiers or are dependent upon their bounty, then the editor is but a hireling; and when he writes to order, he prostitutes journalism. It is a miserable part to play and it is easily unmasked. Among well informed men the real control of most papers is known. The secret is hard to keep, for it discloses itself by damnable coincidence. In technical journalism the atmosphere, on the whole, has been untainted, for the simple reason that this class of periodical permits of the construction of water-tight compartments. The editor writes to interest the reader who is a likely purchaser of the machinery or material offered for sale on the advertising pages. The goodwill of the paper is based on the fact that it reaches the special person whom the advertiser wants to attract. Anything that diminishes the trustworthiness of the information given in the reading pages must injure the value of the advertising pages as a means of publicity. 'Puffs,' 'write-ups,' and 'reading notices' are not only dishonest but they are intensely stupid, in that they diminish the value of the paper as an advertising medium. An advertiser who bullies the management into inserting any of the insincerities of a 'write-up' into the reading pages is injuring himself; he is directly lessening the efficiency of the display for which he pays. Our reading pages are not for sale at any price; our advertising pages are for sale at a fixed price. The two must be kept distinct and separate. It then remains only for the editorial staff to issue a paper that shall be read because it is interesting, and interesting because it states the truth. Of the several ways of telling the truth, it is the aim of serious journalism to select the one that is most useful for the purpose in hand. In the case of the *Mining and Scientific Press* it is our aim to tell the truth, in an interesting and convincing manner, with a view to furthering the best interests of the mining industry and the honor of the mining profession.

# The Besshi Mine and Shisaka Smelter

By H. FOSTER BAIN

Among the great copper mines of the Far East is the Besshi, which is on Shikoku island in southern Japan. Travelers to and from the Orient pass within a few miles of the property as they go from Moji to Kobe through the wonderfully beautiful Inland sea. The mine is the property of the Sumitomo family by right of discovery and has been in their possession for more than 200 years. It was found in 1690 and after being successfully worked by native methods through the intervening years was opened according to modern plans in 1874 under the advice of a French engineer. It is credited with a total production of

quartz schist has been mineralized by the addition of pyrite and chalcopyrite; the latter occurs in streaks in the pyrite, and the whole probably represents a replacement of the quartz. Formerly considered a bedded deposit, it is now spoken of as a vein and is thought by some to represent a fissure filling; the more brittle quartz having been broken while the schist bent under pressure. The vein is known about 6000 ft. along the strike and the single great ore-shoot is 5000 ft. long. The orebody is 2 to 25 ft. wide, with an average of about 7 ft. It has been followed to a depth of 2150 ft. without diminu-

FIG. 1. CROSS-SECTION OF BESSHI MINE.

475,250,000 lb. of copper to the close of 1910, and in 1911 yielded 15,145,070 lb., ranking thereby second only to the Ashio among Japanese copper mines. The mine has long been wholly under Japanese direction, and the family owning it is one of the most progressive in the Far East. Baron Kichizayemon Sumitomo, the present head, is a younger brother of Prince Tokudaiji and Marquis Sainoji, having been adopted into the family in 1892 at the age of 28. He resigned from the House of Peers in order to devote himself entirely to the business affairs of the family. Aside from the Besshi mine, the holdings include the smelter at Shisakajima, the Tadakuma colliery in Chikuzen, the Sumitomo Electric Wire & Cable Works, and the Japan Steel Mfg. Co. works at Osaka. On the occasion of the recent visit of the American engineers to Japan the party enjoyed the hospitality of Baron Sumitomo at his villa near Osaka, and visited the smelting works at Shisakajima. Lack of time prevented a visit to the mine and rolling mills. The following description, therefore, so far as it relates to the mine, is based principally upon published data, generously supplemented by information given by Keijiro Nakamura, superintendent of the smelting works and an accomplished engineer familiar with the best mining practice both in America and Japan.

The Besshi mine is in an area of crystalline schists grouped by Japanese geologists with the Archean. The system of schists is indeed considered to form the upper part of the Archean and to be pre-Paleozoic in age, though in places the rocks are distinguished with difficulty from the oldest Paleozoics. Probably in the United States the rocks would in the main be considered to belong to the Algonkian. At the mine the schists are described as chloritic and graphitic. Piedmontite is abundant and serpentinized dikes are found some distance from the vein on the hanging-wall side. The ore proper occurs in a body of 'quartz schist' that conforms in strike and dip with the general formation of the country, and which, accordingly, has been commonly considered to be a bed. This

tion in size or decrease in value. The ore averages 3 to 4% copper and is believed to be primary. Any possible zone of secondary enrichment was probably mined through over a hundred years ago. One peculiar feature is that the ore carries practically no gold, silver, antimony, or other accessory metals. This is the more striking since

FIG. 2. NAKAMURA NODULIZING MACHINE.

the beautiful stibnite crystals seen in mineral cabinets around the world come from the same region. So free, however, is the copper ore from other metals, that it is not refined electrolytically, and to avoid contamination barren rock is quarried for flux instead of buying the usual silicious gold ores. The refining of the copper, in fact, is conducted according to the usual Lake Superior practice, and in the London market K. S. ingots command a slight premium, just as Lake copper does in New York.

The mine is situated about ten miles from the ocean and about 4000 ft. above sea-level. The vein dips into the mountain at about 50°, and, under direction of the French engineer already mentioned, was opened by means of an inclined shaft which extended 1782 ft. down the

dip. Various adits have been driven to connect the workings with the surface. The 'Third' adit is the upper one shown in the subjoined sketch. It is 6000 ft. long, 10 by 11 ft. in cross-section, and is used as a main haulage and drainage level. Recently a connection has been driven through to the other side of the mountain as shown in the sketch. A stream has been diverted so that it now flows through the mine, thence by ditch about two miles to a convenient site, whence the water is dropped 1800 ft. and by means of Pelton wheels 6000 kw. is generated. A fourth adit is now being driven from Hateba, the end of the private railway used to convey ore from the mine to the docks. It is 10 by 13 ft. in cross-section and will be 16,000 ft. long. Last fall about 2000 ft. had been driven and the face was advancing 200 ft. per month. Power drills are used, and the whole face is blasted in one bench. To meet this adit a shaft is being sunk from the present adit, starting 500 ft. in the hanging wall. This is to be a round, brick-lined shaft, 16 ft. in diameter, and will be 1875 ft. deep. It will cross the vein and meet the new adit in the foot-wall. It is interesting

by launder to another plant about 1900 ft. below which is made up of 152 boxes each 12 ft. in length, 8 ft. in width, and 4 ft. 6 in. deep, sloping at 1 to 44. These boxes are arranged in four series, in each of which the water flows up and down. In this case scrap iron and coke are used as precipitants, consumption of the former being 23% of the precipitate produced. The precipitate taken is on the average 50 tons a month which contains 8% copper. The coke, in which the precipitate is absorbed, is produced to an amount of 200 tons per month which has 1% copper. All these products are sent to the smelting works at Shisakajima."

The cement copper from inside the mine, where boxes are placed at convenient points, averages 80% Cu; that from the outside boxes is of lower grade, owing to the presence of dust and iron oxide. From the precipitation plant the water is conducted by flume  $9\frac{1}{2}$  miles to the sea, so that there may be no possible chance of injury to crops growing below the mine. The ore is loaded on barges which are made into trains and hauled by tugs about ten miles to Shisakajima (Shisaka island), to

SUMITOMO SMELTING WORKS, SHISAKAJIMA, JAPAN.

to note that this deep-level work is being carried out without preliminary drilling. The persistence of the ore-shoot to a depth of 2000 ft. undiminished in size or value, leads to confidence in its continuance for 1800 ft. more.

Methods of working at the mine, which is under the charge of K. Arai as mining engineer, consist of the ordinary driving of levels and overhand stoping. Schram, Leyner, and pneumatic drills are used with Rand, Leyner, and Schram compressors. Westinghouse electric locomotives gather the ore-cars, and Knowles pumps handle the water—about 40 cu. ft. per minute. Owing to the character of the water, phosphor-bronze pump parts are necessary. Aerial tramways carry the ore to the railway. No concentrator is necessary, but in sorting-houses the mine product is separated into 10% waste, 70% lump, and 20% fine material. As in most Japanese copper mines, great pains are taken to purify the mine-water before running it to waste, and particularly to precipitate all copper. There are two cementation plants, and both scrap iron and coke are used to throw down the copper. About 180 tons of cement copper is saved per year. The precipitation plant is described as follows in a report issued by the Bureau of Mines:

"The mine water from the third adit is sent to 90 wooden boxes, each 8 ft. in length, 3 ft. wide, and 1 ft. deep, which contain scrap iron; the slope being at the rate of 1 in 5.5. The average production of the precipitate is 35 tons per month which contains 50% Cu. The water which has passed through these boxes is conducted

which in 1904 the smelting works were removed in an effort to avoid danger from smelter fume.

At the smelter about 600 tons of ore per day is handled, containing 30 to 33% S. With this is used 7% of gneiss as flux, and 4 to 5% coke.

The fine ore was formerly briquetted, but Mr. Nakamura has developed an alternative process which is now used. Noticing that some of the fine ore which had become wet while being transported, showed a tendency to 'ball up', he experimented by allowing the ore mixed with varying amounts of moisture to roll down a slope. This led finally to the device shown in Fig. 2. It consists essentially of a conical wooden cylinder revolving on a horizontal axis. It is 8 ft. long, 3 ft. in diameter at the upper end and 5 ft. at the lower. Into the upper end is fed a mixture consisting of fine ore, 100 parts; flue-dust, 20; silicious flux, 40 to 50; water, 6 to 7%. The exact amount of water necessary was determined by experiment and seems to be important. The mixture as it rolls down to the delivery end agglomerates; the individual balls being half to three-quarters of an inch in diameter. The effect of the water seems to be purely mechanical, but it forms a bond sufficient to hold the mass together and permit successful pot-roasting, which is conducted in the pot shown in cross-section in Fig. 3. It also saves about 30% in the time necessary to conduct the operation. The pots used are essentially circular grates with shallow sides. They are made of steel and are set over firebrick-lined pits into which a blast is directed from a Root blower. They are covered by a

heavy sheet-iron hood luted at the sides with sand. In the top of the hood is a conical-bottom trap-door, similar to the top of an iron blast-furnace, through which additional material may be introduced during the roasting process. Below the trap are baffle-plates to scatter the charge. At the sides of the pit, above the grate, are outlets for the air and gases.

The fine ore which is roasted in this device contains about 2½% Cu and 30% S. With it is mixed, as noted, the gneiss used for flux, and the flue-dust, which contains about 2% Cu and 10% S. The first material placed upon the grate is burning pyrite, which is spread about 1½ in. deep. Over this is placed a layer of hot dust from the pot last dumped, and then three tons of the fine-ore agglomerate. The pot is then covered, and the blast (about 40 mm. pressure) turned on. At intervals during the next four hours three additional charges of three tons each of ore are fed into the pot. In all, about 12½ tons is roasted in four hours. On completion of the roast the cover is

FIG. 3. NAKAMURA ROASTING POT.

lifted and the pot raised and turned, dumping the charge upon iron domes so as to break the sintered mass into convenient pieces for handling.

The roasted fine ore, with lump ore and coke, are fed to the first blast-furnace. This produces a matte containing 20% copper and a slag with 0.2% copper. The matte is smelted a second time, bringing it up to 30 or 35% copper and making a second slag assaying 0.3%. This matte is roasted in stalls and then smelted in a cupola furnace, bringing it up to 60 or 65% Cu. The slag from this furnace, assaying 0.8% Cu, is sent back to the first blast-furnace. The white metal is delivered to a reverberatory furnace, where a strong air-blast is blown over the top while a slag is rabbled off which is returned to the cupola. The product from this reverberatory is 98 to 99% copper. It is cooled in the air, no fresh water being available on the island, and finally melted, and poled in a refining furnace, from which it is cast into ingots. In all about 7000 metric tons per year is produced. Of this, about one-fourth is made into sheets and wire at the Sumitomo works at Osaka. The remainder is shipped in the form of ingots to Hamburg and London.

The Shisaka works are well and substantially built. They include coke-ovens from which the waste heat is utilized in boilers, and all modern devices and conveniences. The company provides homes, schools, and hospitals for its 4800 employees and brings fresh drinking water from the mainland. Wages are equivalent to 40 or 50c. per day,

but it is to be remembered that houses, including water and baths, are rented to employees at a rate of 7½c. per month, and that rice, wood, and other supplies are sold at fixed rates less than their cost. With free medical and hospital service, here as at other works in Japan, mere statements of wages do not measure costs to the company or benefits to the men. The people look prosperous and happy. They were evidently well fed and cared for, and the company is known to be making an excellent profit. The American engineers steamed away from the hospitable harbor to the accompaniment of salutes and daylight fireworks, with the comfortable feeling of having seen good work well conducted.

## The Sicilian Sulphur Industry

By ARTHUR GARRELS

\*In 1911 in all of Sicily there were 476 sulphur mines and 13 refineries in operation. Adult mine workers receive an average of 3 lire (\$0.579) per day; boys, 1.50 lire (\$0.289). The scale of daily wages in the refineries varies from 3.50 to 9 lire (\$0.675 to \$1.737). The methods employed in mining sulphur in Sicily range from the most primitive to the latest and most improved. In smelting, the sulphur itself is used as fuel, and, according to the device and method employed, 25 to 40% of the mineral is thus consumed.

All crude sulphur produced in Sicily must be sold to the Consorzio Obbligatorio per l'Industria Zolfifera Siciliana (Compulsory Society for the Sulphur Industry in Sicily), the Government monopoly. The price paid by the Consorzio is fixed each year, in July, and for 1911 was as follows per metric ton of 2204.6 lb: Buying, \$17.466; selling, \$18.225. Export prices per 100 kg. (220.46 lb.) f.o.b. Catania for crude and refined and milled sulphur, ranged as follows:

Kind of sulphur.	High.	Low.
Crude .....	\$1.93	\$1.775
Second crude, ground, best.....	2.196	2.161
Second crude, ground .....	2.161	2.123
Refined .....	2.103	2.084
Refined, ground .....	2.354	2.316
Rolled, refined .....	2.161	2.123
Sublimed .....	2.895	2.895

According to the report of the Consorzio Obbligatorio per l'Industria Zolfifera Siciliana, the total production of sulphur during the fifth working year, ended July 31, 1911, was 391,978 tons, against 396,737 during the preceding year. The decrease of 4759 tons was due to general conditions, and in particular to the destruction, by an explosion, of one of the more important mines, producing an average of 30,000 tons per annum.

## Aluminum Prices Fixed

The International Aluminum Syndicate has now fixed the price of the metal for next year's delivery at 160 marks per 100 kg. (\$380 per metric ton of 2204.62 lb.), with the usual increase for special brands. The syndicate, however, will not dispose of the entire output for 1913 at this price, there being a general view among members that production during the next twelve months will not be able to keep pace with consumption, and that still higher prices will be possible. On the other hand, the syndicate has all along been emphatic in asserting its intention of in no way handicapping the development of the aluminum-consuming industries by unduly raising prices. At \$380 per ton manufacturers have quite a good margin of profit, though the price cannot be considered at all excessive in view of the present levels of metals generally, and particularly of copper and tin. It is understood that manufacturers are making arrangements to increase production should demand warrant it.—*Manchester Guardian*.

\*From a consular report.

## Prospecting for Vanadium

By FRANK L. HESS

'It is comparatively few years since the average prospector looked only for ores which carried gold, silver, copper, lead, or zinc. Within the past few years, however, he has been examining carefully all strange rocks and minerals in the hope that they may carry one of the 'rare metals.' Some of the forms in which the rarer metals occur, such as carnotite and vanadinite, at once attract attention, but many are so similar to minerals of no value that they are scarcely noticed. For instance, the vanadium deposits of the Placerville region, Colorado, were unsuspected of value for years after gold deposits had been worked in their immediate neighborhood. It may be worth while, therefore, to tell something of vanadium and its value and to describe some of the vanadium minerals and their manner of occurrence.

Vanadium has been known about a hundred years and was first found in lead ore—vanadinite—from Mexico. There was, however, little market for vanadium ores until after the demand for alloy steels was created within the past ten years through finding that remarkable qualities are imparted to steels upon the addition of comparatively small quantities of some of the less common metals. Vanadium, it is claimed, when added to certain steels, greatly increases their resistance to shock and their durability under torsional strains. It is also claimed that tool steels are made much harder. So well have these claims been substantiated that large quantities of automobile and engine parts, gears, and other mechanical appliances are now made from steel treated with one-twentieth to one-fourth of one per cent vanadium. Vanadium is also used in tool steels in percentages reaching to 1½. In the milder steels, vanadium is thought to act as a scavenger, ridding the steel of oxygen, nitrogen, sulphur, and possibly other impurities. In larger quantities it is said to act both as a purifier and as a hardener, but for this purpose it is used in connection with chromium, generally tungsten, and sometimes manganese. It is also used in babbit metals and in bronze. Considerable quantities of vanadium oxide are used in dyeing cotton black, a little is used in giving a yellow-green color to pottery glazes, and small quantities go into other uses. One 'solution of vanadium' is being advertised as a sort of cure-all.

The vanadium used in steel is introduced as ferro-vanadium, an alloy of iron and vanadium containing from 20 to 50% vanadium. It is made by two methods, electrolytic smelting and the thermit process. In the latter the heat is generated by the rapid oxidation of finely crushed aluminum, and a very high temperature is obtained. Metallic vanadium is prepared with very great difficulty, owing to its affinity for oxygen and nitrogen and has never been obtained except in small quantities.

The price of vanadium has dropped in the past two or three years from \$5 per pound for the vanadium contained in ferrovanadium until it can be bought at the present time for \$2 per pound, and prophecies are heard that it will go even lower, owing to the quantities now being mined in Peru and Colorado.

Vanadium is found in minute quantities in most, if not all, igneous rocks, in many clays, in the ash of some coals, in asphalts, peat, sandstones, and veins of various kinds. The minerals in which it occurs in commercial quantity, however, are few and sparsely distributed.

Carnotite, a complex variable compound of vanadium and uranium with potassium and calcium, is ordinarily a powdery canary yellow mineral. It is now mined in quantities in sandstones of western Montrose county, Colorado, in Paradox valley and vicinity, where it forms an impregnation in the sandstone and coats crevices. In places it

shows no crystal form even under a lens, but in other places it can be seen with the unaided eye to be in crystalline plates, generally standing at right angles to the surfaces which are coated by it. Rarely it is found in a bright yellow mass which cuts like tale. The material as mined may contain 4% or even more of  $V_2O_5$ , and the percentage of uranium oxide ( $U_3O_8$ ) present is usually in the ratio of about 3 to 1. The area is 50 miles from a railroad, and heretofore the ore could not be mined profitably if it contained less than 3%  $V_2O_5$ , and it probably must be richer since the price of vanadium has reached its present low mark, unless the uranium is also sold. The pure carnotite contains from 19.85 to 21.09%  $V_2O_5$  and 58.75 to 61.53%  $U_3O_8$ .<sup>1</sup> The origin of the ore is at present unknown. Carnotite is also being mined 15 miles west of Greenriver, Utah, on the San Rafael river; in Professor valley south of Cisco; near Richardson; 8 miles south of Thompsons; in White Horse canyon; and other parts of the La Sal mountains. Considerable quantities are said to exist in Rio Blanco and Moffat counties, Colorado, and Uinta and Carbon counties, Utah. In each of these places it has been found in friable sandstone which is probably mostly of Triassic age. A little carnotite is found in South Australia in a pegmatite dike, where it occurs as a decomposition product from a uranium-bearing titanium mineral called davidite. Carnotite is highly radioactive, as would be expected from its high uranium content, and is being used in several laboratories for the extraction of radium.

Calcium vanadate, a red mineral in small red columnar crystals, reminding one of finely divided redwood bark, though a richer red, occurs with the carnotite in Paradox valley; south of Thompsons; and in Wild Horse canyon in the southeast part of the San Rafael swell, where some carnotite occurring with asphaltic material has been mined. It is also found at Minasragra, Peru, in connection with patronite in asphaltic material.

Patronite, the sulphide of vanadium, is found in large quantity at Minasragra, near Cerro de Pasco, Peru, in connection with asphaltic material and is shipped in large quantity to this country. The material as mined is a dark, almost black, structureless mass. It is easily set afire with a match, and advantage is taken of this property to burn out a large part of the sulphur before shipping. The roasted product contains about 25% vanadium. Patronite is not known in any other part of the world, though it seems possible that it may be found in this country, as vanadium occurs in connection with asphaltic material at several places. Near Page, Oklahoma, a material often referred to as coal is really an asphalt related possibly to grahamite. It is hard, brittle, and shiny black, and contains about 0.8% ash of which one-eighth to one-fifth is vanadium pentoxide ( $V_2O_5$ ), equivalent to about 0.1 to 0.19%<sup>2</sup> of the whole. It has not yet been utilized for vanadium. Brief reference has already been made to the Wild Horse canyon deposit in the southeastern part of the San Rafael swell, Utah. There carnotite, calcium vanadate, and possibly other vanadium and uranium minerals occur in a sandstone impregnated with a shiny asphaltic material. Deposits more or less similar to those at Page, Oklahoma, occur in the Yauli district, Peru, at San Rafael, province of Mendoza, Argentine Republic, and other places. Some effort has been made to burn the material and extract the vanadium from the ash.

Roscoelite, a dark green vanadium-bearing mica, is the mineral from which the larger part of the vanadium produced in this country is obtained. Though found in small quantity in gold mines on the Mother Lode, California; at Baker City, Oregon; and in Boulder county, Colorado, the only place it is known to occur in commercial quantity is in San Miguel county, Colorado, in a belt about nine

<sup>1</sup>Hillebrand, W. F. U. S. Geol. Surv. Bull. 262, p. 27. In commercial work uranium is usually determined as  $U_3O_8$ , but the figures above are as given by Mr. Hillebrand.

<sup>2</sup>The latter figure is given by D. Foster Hewett, *Trans. Amer. Inst. Min. Eng.*, Vol. 40, 1909, p. 280.

\*Published by permission of the Director of the U. S. Geological Survey.

miles long by one-half to two or three miles wide. Here it occurs in a fine-grained sandstone known as the La Plata, of Jura-Trias age, in general nearly white, but which is stained in places a dull green by roscoelite. The sandstone has a parting which is possibly due to a nonconformity, and along this in many places is a dark green to brownish black shaly material, one-half to three-fourths of an inch thick, which is really a vein of roscoelite with a little quartz. The mica scales are so small that they cannot be seen by the eye. Above or below the seam or both above and below, the sandstone is impregnated with still more minute scales of roscoelite for a thickness of a few inches up to more than 30 ft. Roscoelite carries between 13 and 14% vanadium, the impregnated sandstone up to about 4%, and the vein more than 8%. In color, the vanadiferous sandstone, though somewhat duller, is much like the green sandstone found in the Coast Range from Colusa county, California, to Washington, which is used for building in San Francisco, Tacoma, and elsewhere.

Vanadinite, a vanadate and chloride of lead, is the commonest of the vanadium minerals. This mineral occurs in many colors and outward forms and is one of a family of minerals varying considerably in composition. Perhaps red is the color most often met with in vanadinite. It is also reddish brown, hair-brown, yellow, gray, pearly, and colorless. The crystals are six-sided, many are barrel-shaped, and many are hollow ended. Cross-sections are very apt to show growths of various colors. It is a soft mineral with a hardness of about 3, is heavy (specific gravity of 6.66 to 7.23) and so is easily saved by panning. It is found at many places, especially in the southwestern part of the United States in the oxidized portions of lead-bearing veins. The properties named are almost characteristic, the only minerals which might be mistaken for it are pyromorphite and mimetite, the phosphate and arsenate of lead, to which it is closely related. The test for vanadium is necessary for differentiation from these. Endlicheite, in which arsenic largely takes the place of vanadium, is a clear yellow variety found at Hillsboro, New Mexico, and at other places.

Descloizite is a mineral of much the same characteristics and composition, but it crystallizes in the orthorhombic system, generally in very small crystals, and contains zinc. It occurs under the same conditions as vanadinite, but is generally in small quantity. Descloizite is found in the Clark mountains, California, and at a number of places in Nevada, Arizona, and New Mexico. A copper-bearing variety is green and is called cuprodescloizite.

The lead vanadates are mostly confined to the dry areas, though some vanadinite is found in Montana and less quantities in other regions of large rainfall. Mexico, Argentina, and Spain produce considerable quantities of vanadinite.

Mottramite, a lead-copper vanadate, has been mined in a small way in England, but is unimportant, and unknown elsewhere.

There are other vanadium-bearing minerals, but up to the present time these are the only ones known to be of direct commercial importance. As is well known, the iron ores of Taberg, Sweden, carry vanadium, and from the slags of the Crenot iron works in France large quantities vanadium oxide are said to have been recovered yearly. The titanite iron ores of the Adirondacks (New York) carry small percentages of vanadium, but there is little present prospect of a recovery from that source.

From the brief description of minerals and occurrences given it follows that from present knowledge the prospector for vanadium appears to have more chance for success in the drier part of the United States; that is, the Great Basin and southwestern states. The following substances, unless of known composition, may well be tested for vanadium: Dull green sandstones and other rocks *not igneous*, especially where only certain parts of a bed are so colored; hard asphaltic material, either impregnating sandstones or in veins; bright yellow coatings and stains; hexagonal minerals of various colors which are easily

crushed and have a specific gravity somewhat higher than pyrite, shown by the way they hang back in panning; resinous coatings on crevices in rocks; and dull green micas.

Luckily the qualitative tests for vanadium are so easy that any prospector can ordinarily make them for himself. An analysis to show the quantity present, however, must be made by one with some chemical skill who also has the requisite apparatus. To test for vanadium the powdered mineral may be digested with either dilute or concentrated nitric acid, and if vanadium is present a greenish solution generally results. If hydrogen peroxide be added to the resulting liquid a brown color will appear if vanadium is present. Some vanadium minerals are also attacked by hydrochloric acid and by dilute sulphuric acid. If concentrated hydrochloric acid is used, vanadium minerals generally give a green solution the color of which becomes faint or disappears on dilution. The addition of hydrogen peroxide to either the hydrochloric or the sulphuric acid solution gives a brown color, as when nitric acid is used. Metallic zinc may be added after hydrogen peroxide and a bright green or blue color will be given by the reduction of the vanadium compounds. The same effect can be obtained in a nitric-acid solution by adding sulphuric acid, evaporating to white fumes, diluting, and adding metallic zinc. If preferred, hydrochloric acid instead of sulphuric acid may be added to the nitric-acid solution, but in that case evaporation must be carried almost to dryness at least twice to get rid of the nitric acid. The liquid may then be diluted and more acid added, followed by zinc as described.

At times the tests given above are not wholly satisfactory. In such cases, if the apparatus is at hand, through a filtered solution made alkaline with ammonia pass hydrogen sulphide ( $H_2S$ ) gas until the solution is saturated. The solution will take a fine garnet or deep wine color if vanadium is present. Copper, if present, is precipitated as a sulphide and does not interfere with the test.

## Extensions of the Lake Copper District

Speaking before the Lake Superior Mining Institute, F. W. Denton, in his presidential address, alluded to the fact that developments of the past year or more give rise to the expectation of a considerably enlarged area of mining operations, although the greater part of the district has not yet been systematically explored. At present, attention is mainly concentrated on economies to be effected in mining and milling methods, with the numerous special problems incident thereto. Among the foremost are greater efficiency in the work underground, including improvements in machine drills; the perfecting of safety devices; the use of concrete to replace mine supports and shaft timbering; the cheaper generation and application of electric power, particularly in connection with low-pressure or mixed-pressure steam turbines; better extraction of copper from the mill through fine grinding, etc.; along all of these lines noteworthy progress is now being made.

## Tin Statistics

In a report by L. Vogelstein & Co., on the August tin statistics, published by the Metal Exchange on September 4, it is said that the statement is more favorable than anticipated. The visible supply was 11,285 tons, a shrinkage of 2061 tons, mainly due to large London, Holland, and Continental deliveries totaling 4300 tons, following the small July deliveries of 3000 tons. Since the beginning of the year the visible supply has decreased 5229 tons, including four Banka sale months, and four non-Banka sale months. At the present ratio of decrease, the supply at December 31 will be very low. The previous low record was 9839 tons, on April 30, 1907, the price at that time being £195 in London, and \$42.80 in New York. The financial crisis of that year prevented further rise in prices, and stocks increased to 23,000 tons on January 31, 1910.

## Outcrops of Precious Metal Veins

By FREDERICK H. MORLEY

The physical features of the outcrops of precious metal veins are of great interest to prospectors, practical mining men, and field engineers, for the outcrops usually determine the location of mining claims, often lead to the discovery of orebodies, and usually indicate the size,

OUTCROP OF A STOCKWORK, WENATCHEE, WASHINGTON.

direction, and continuity of the vein. The average prospector cares little about ore genesis or the chemical features of the superficial alteration of mineral veins, but he is always much impressed by bold outcrops. He is usually hunting for prominent projecting vein outcrops which can be readily seen and easily traced on the surface. There is a strong popular feeling that the finding of a 'true fissure' vein having a marked continuous outcrop must lead to the discovery of rich ore deposits. In a large number of cases, the valuation which an owner places upon an undeveloped prospect is proportional to the boldness and length of the vein outcrop, irrespective of its chemical composition or the actual presence of ore minerals. It is almost an axiom among many miners that the depth of a vein (presumably in commercial ore) will be at least equal to the distance on the surface over which its outcrop can be traced.

Although the presence of bold outcrops affords the prospector the greatest assistance in the discovery and location of veins, yet such outcrops cannot be relied upon as indicative of the presence of orebodies, nor of the size and continuity of the vein in depth. While it may be perfectly true that few valuable precious-metal deposits would have been found had it not been for the existence of some conspicuous outcrops, yet it seems to be equally true that a large proportion of the most productive precious-metal veins of North America are not characterized by such outcrops, and that their discoveries were largely fortuitous.

In the very interesting and instructive paper on 'Outcrops of Orebodies,' in the *Mining and Scientific Press*, December 4 and 11, 1909, W. H. Emmons gives a classification of outcrops based upon the chemical and mineralogical composition of various kinds of ore deposits and their enclosing rock formations. According to general superficial features and aspects, outcrops might be rudely classified as: (1) bold or projecting, (2) level or flat, (3) depressed, (4) concealed. Or a still more general classification might designate outcrops as: (a) conspicuous, (b) obscure, and (c) concealed. The character of the outcrop would, of course, depend upon the composition of the vein and the country rock, and also upon climate, topography, etc., as shown by Mr. Emmons;

but the general superficial aspects and characteristics are of considerable interest to prospectors and locators of new mining properties.

The composition of the vein and the climate of the region are the most important factors in determining the character of the outcrop, since bold outcrops are only possible in regions which have been subjected to intense and rapid erosion, where the veins are more resistant to decomposition, weathering, and erosion than the enclosing rocks. Bold projecting outcrops are generally silicious, and are most frequently found in arid regions. In moist climates erosion is often hindered by soil and vegetation, while in regions that have been glaciated, veins and country rock have been equally eroded. Bold outcrops are most often composed of solid quartz, silicified rock, or other resistant substances, with little or no admixture of the easily decomposed ore minerals. They are, therefore, likely to be barren, although some valuable orebodies may be found in connection with such barren outcrops—for example, the silicious outcrops or 'combs' of the Goldfield district. Outcrops may be obscured or concealed by soil, talus, or vegetation, or may be covered by rock formations which are later than the veins. Those of this type are probably the most numerous of all, but discoveries have been greatly hindered on account of the more or

OUTCROP OF STRATTON'S INDEPENDENCE.

less complete concealment of the apex of the vein. In many cases a portion of a vein may appear at the surface at some point, from which the concealed apex of the vein can be traced by trenching or underground workings. Most of the veins of the Cripple Creek district are concealed by detritus; and those of the El Oro district are

concealed by a capping of later andesite that covers them.

It seldom happens that the entire outcrop of a vein will belong to one of the classes mentioned, since local conditions may vary greatly along the strike of the vein. One part of a vein may be covered by detritus, another part may outcrop boldly, while the ore-bearing portion of the vein may have depressed outcrops due to the more rapid erosion and decomposition of the ore minerals. Undoubtedly the large majority of precious metal veins have obscure outcrops which are not easily identified except at a few isolated places along the course of the vein, if at all.

In general, it may be stated that the importance of bold outcrops as a factor in the discovery of valuable metalliferous veins and ore deposits is greatly overestimated. If one takes a list of the most productive and valuable precious-metal mines or districts of North America, he will find that a large majority of the veins have obscure outcrops, and that their discovery was largely fortuitous. The histories of most of these mines or districts are singularly silent regarding the vein outcrops, and little mention is made of them in connection with the discoveries. Such a list as has just been mentioned would include mines such as those of the Comstock Lode; the Homestake; Goldfield Consolidated; Ontario; Silver King; Daly West; Alaska Treadwell; Bunker Hill & Sullivan; Esperanza; El Oro; Valenciana (Guanajuato district); San Rafael (Pachuca district); Portland (Cripple Creek district); and Nipissing. This being a representative list of a number of the most important precious-metal mines of North America, general conclusions reached from the study of the histories and geological reports with respect to the outcrops of these veins should be interesting and instructive.

The ore deposits of the Alaska Treadwell and Homestake mines do not occur in veins, consisting at the former of mineralized dikes intrusive into black slates; and at the latter of impregnated crushed zones of slate. The orebodies of the other mines occur in veins or lodes, or in connection with them.

The Homestake ore-zone showed a great extent of iron-stained rock at the surface which carried gold, but the ore deposits evidently had no bold outcrops, although they may have been rather conspicuous on account of their coloring on the surface. The northern part of this ore-zone is completely concealed and covered by later formations. The Alaska Treadwell orebodies consist of mineralized dikes. A. C. Spencer<sup>1</sup> says that "in the greater part of the intruded area exposures are few, and only small dikes outcrop on the side toward the centre of the island." The quartz veins in the black slates which have been prospected show some mineralization, but their value is doubtful.

Bold outcrops are found in only two or three of the mines enumerated, such as the veins of the Tonopah Mining Co., and the silicious ledges or 'combs' of the Goldfield district. The great Comstock Lode showed scattered outcrops of quartz, but these were evidently not of sufficient prominence to attract the attention of the early prospectors, so that the discovery of this lode was largely fortuitous. The projecting outcrops of the Mizpah vein led to the discovery of the rich ore deposits of the Tonopah district, although many of the important veins were covered by a capping of later andesite. The rusty, silicious lodes of the Goldfield district were passed by and overlooked by prospectors for many years. In the Coeur d'Alene district the veins usually have flat or level outcrops, which are obscure. F. L. Ransome<sup>2</sup> states that "the outcrops of the largest lodes and orebodies are very inconspicuous and probably would not attract the attention of even a keen observer traversing the country in the ordinary way." In the San Juan region of Colorado the veins usually have depressed outcrops, but they are fairly

conspicuous on account of their trench-like appearance and rusty color. The Camp Bird veins are partly covered by talus, but can be traced for considerable distances on the surface. In some parts of the San Juan region which are covered by the Potosi rhyolite the veins do not outcrop at all.

The Ontario lode, Park City district, has some outcrops, but they are very obscure. The discovery was made by finding "a little knob sticking out of the ground about two inches high,"<sup>3</sup> which is said to be the only cropping of this lode which was ever found. The Daly West mine is situated on the westward extension of the Ontario lode, but "croppings of the Daly West lode are not known, the probable position of its apex being masked by glacial deposits."<sup>4</sup> The rich orebodies of the Silver King mine did not outcrop, with the exception of the Mayflower shoot. This shoot was accidentally discovered when some isolated outcroppings showed rich ore at one point on the surface, but no extension could be observed.<sup>5</sup> In general, the lodes of the Park City district have obscure or concealed outcrops, largely due to the presence of extensive glacial deposits.

The Veta Madre at Guanajuato, and the Vizcaina vein at Pachuca, have rather obscure outcrops, although both veins have been traced for long distances. F. Beck<sup>6</sup> states that the Veta Madre "has a generally obscure outcrop," and is in part concealed by later flows of lava. Many of the veins of the Pachuca district have prominent outcrops which can be seen as white crests running across the surface for long distances. The Vizcaina lode, of the San Rafael mine, was discovered accidentally, being covered by a mass of detritus and having a generally obscure or depressed outcrop. Both the Vizcaina and Santa Gertrudis lodes are indistinct or concealed by detritus at the surface, the great orebodies having been found only at a depth of 100 metres or more. In the Cripple Creek district there are very few outcrops, on account of a heavy covering of soil or 'wash.' The vein croppings are usually obscure, if not entirely concealed. Some lodes, like the 'Captain system' of the Portland mine, apparently do not reach the surface at all.

The rich silver veins of the Cobalt district, being almost entirely covered by heavy deposits of glacial drift, were accidentally discovered through a railway cut. The veins and country rock have been equally eroded by glaciation, so that the vein outcrops are level. The principal veins of the Esperanza, El Oro, and Dos Estrellas mines in the El Oro district, Mexico, are completely concealed by a thick capping of andesite. The original discovery was made on the Descubriadora vein of the El Oro mine, which was an outcropping vein not covered by the lava capping,<sup>7</sup> but the San Rafael vein system (the principal one of the district) and the Dos Estrellas veins are completely covered by the andesite.

Of the veins enumerated, only some of those of the Goldfield and Tonopah districts, parts of the Comstock Lode, and some of the Pachuca veins appear to have bold projecting outcrops. The ore zones of the Homestake mine, and some of the veins of the San Juan district, Colorado, are conspicuous on account of their coloring, decomposition, or erosion. In the cases of all of the other veins mentioned, the outcrops are either obscure or concealed. The general conclusion is that the large majority of the important precious-metal veins of North America have obscure or concealed outcrops, and that bold outcrops are rarely indicative of valuable ore deposits, the popular impression to the contrary not being founded on evidence; and, like the fallacy concerning the 'true fissure vein,' more likely to prove misleading to the prospector than to serve as a useful guide.

## Pioneering in the Tropics

By C. M. EYE

Those who have never had to do with the development and equipping of mines in the tropics, remote from a base of mining supplies, and devoid of any supply of labor trained in the lines of work required, can have no realization of the many difficulties met, or of the many problems that have to be solved in order to attain success. Such difficulties and problems, unless anticipated, are sure to cause expensive delays. Having been 'up against' these problems, I hope, by contributing the results of my experience, to help others of the profession who may find themselves in a like situation.

'Cheap' tropical labor is usually slow, and has almost

a liberal allowance be made for unforeseen contingencies, and this is especially true in tropical situations. Whereas 5 or 10% may safely cover in older districts, an allowance of at least 20 or 25% has often to be made where the enterprise is a pioneer one. It is important to foresee, if possible, just what will be needed in the way of buildings and quarters, and to provide them at the outset of the equipment of a property with a reduction plant. They cost no more then than later, and the men get the benefit at once, which will in turn accrue to the benefit of the company in better service rendered. White men

taken to the tropics must be well housed and fed. Such men are usually of a good class, men brought in to supervise, and are entitled each to a comfortable room alone, where he can do as he pleases without interruption when off duty, and to the best food obtainable. This does not imply that there need be extravagance, for the best food for a given locality is often the cheapest; but no pains or expense should be spared to get a good variety of food for the white force. I consider it good policy, in addition, to provide a club building furnished at the company's expense, with a pool table, phonograph, and subscriptions to the best magazines, and by all means the mining magazines and periodicals, all free of cost to the men. In providing living quarters for white men in the tropics, I have found it best to build a number of houses of not to exceed two rooms, communicating to a common veranda, rather than a lesser number of larger houses, for the reason that more quiet and greater privacy for each man is secured. Native workmen are usually more easily satisfied, for often they have homes near the work, and houses of native material answer their every need. They should all be housed so that they and their families are kept dry and not crowded, and I have obtained steadier work from them when they are housed on the property than when they come in from their own homes; the temptation to stay in on a rainy morning, or to sneak away to a cock-fight or other equally fascinating diversion, is not so strong when they are housed on the works.

Before beginning any construction work, it is quite essential to provide for a good supply of tools, and at the same time to provide ample store-house capacity, so that

CARABAO HAULING MILL TIMBERS, FRONT END RESTING ON 'PATALOI,' CORRESPONDING TO THE 'TRAVOIS' OF FRENCH CANADIAN; BACK END DRAGS.

100-HP. BOILER, EN ROUTE APRIL 1911. HOME-MADE HARDWOOD WAGON DRAWN BY 20 CARABAO.

invariably to be trained for mining work. It is therefore important in opening up tropical mines to keep development work going steadily when once started, working every possible face. The cost of supervision is relatively high, another good reason for this policy, which if carried out intelligently will result in a low development-cost and a goodly reserve of ore, in most cases, by the time reduction is begun. As construction costs in the tropics are usually much higher than operating costs, as compared with similar work in mining centres, I consider that the equipment should be so planned that it will allow at least three, and better four years, to handle the ore in reserve at the time that construction begins, and at no consequent time to crowd the mine any closer than by added milling equipment.

In making estimates for construction in remote districts, where there are no available data as to costs, and no equipment or trained labor at hand, it is essential that

all tools be stored, when not in use, in tool-houses in connection. The store-house force can attend to checking and storing in connection with the foreman, and a strict enforcement of this rule will result in much less loss from thievery or carelessness. I have even found it necessary to require tools to be brought out and checked at the end of each shift in a mine, and reissued to the next shift. No new material should of course ever leave the *bodega* or warehouse except on requisition of a responsible foreman. A company sales-store should always be provided from the start for the convenience of the employees. This should be operated on a basis of very reasonable profit, and food-stuffs should carry the least profit. Under working conditions where goods are not likely to spoil or be otherwise lost, I should say that a profit of 10% on foodstuffs and ordinary clothing and 20% on all other goods is a reasonable basis for operation, and, in addition to providing for the wants of the men, will usually afford sufficient profit

to pay for the clerical help on the job. This should be sufficient return, for the object to be kept always in view in a mining enterprise is to get low costs and good results in mining and milling, rather than to make profits from sales and rentals. Yet I have seen mining operations where these seemed of prime consideration with the management, with heavy losses going on apparently unnoticed in mine and mill. It is, of course, as essential in the tropics as elsewhere that a thorough system of accounting and cost-keeping be started from the very first, but it is seldom done. With many companies the cost of this seems too great, but by the operation of a well conducted store, as I have noted, the expense can be met without dipping into capital account for it.

It is very essential to prepare well at the outset for proper sanitary arrangements, and to provide a doctor and stock of medicines for a tropical camp, and to exercise an eternal vigilance regarding sanitary matters, especially with the natives, for they realize less than whites the importance of sanitation. The cost of a doctor and of medicines can usually be assessed to the employees in part, at least, but in any case it must be provided for. In the Philippines the Insular Government, wherever possible, gives the mining companies the benefits of the provincial hospitals at a very nominal charge, while the district health officers enforce sanitary regulations in the camps, which aids the operators greatly; but all governments are not so liberal nor so well provided for in this line. The best company provision for medical assistance for its employees that has come under my observation is that of the Oriental Consolidated company at Unsan, Korea. There the medical aid is ample, and is not only free to the people immediately employed, but to the people of the district as well. And I believe that it has proved to be a wise policy.

In providing materials for store-houses, living quarters, and offices, there is such a variety in use in the tropics and such a difference in different countries, that it would be waste of space to go into a description of them. Suffice it to say that where there are means for sawing timber, lumber is the most satisfactory, as a rule, for permanent buildings of this class, with corrugated galvanized roofing. I have utilized slabs to good advantage and even for floors of such buildings where lumber and money were rather scarce. A tight ceiling should be put in where the galvanized roofing is used, as otherwise it will be insufferably hot during the day. Where the supply of galvanized iron has to be brought to the property in sea-going boats and unloaded on the beach, the greatest care is necessary to prevent it getting wet with sea-water, which ruins it very quickly by converting the zinc to a chloride. Subsequently, when the iron becomes exposed, a galvanic action sets up which soon results in a hole and a leak. When a good grade and weight (not less than No. 24 gauge) of galvanized roofing is well laid, with a lap of not less than two corrugations and a run of eight or more inches with a minimum pitch of 26°, I know of no more satisfactory roofing for the tropics, and no sheeting is necessary with it, as there is none of the 'sweating' that is so troublesome in cold countries. I have also found that plain galvanized sheets of 24 gauge, or even lighter, make an excellent enclosing material for mill buildings, being easily and quickly put on studding and girts so spaced as to accommodate the regular-sized sheets. It makes an almost fireproof siding, and no other material is required beside it.

Excavation work should be begun as early as possible,

owing to the slowness of natives, and should be pushed at all times. A competent and energetic white should be put in charge of the work, and under him the gangs should be so arranged that there will be a native *capitas* or boss to each 25, or each individual gang of less number. Thus the foreman has to deal only with the sub-bosses, but he must be 'on the job' all the time, not only to keep them going, but to see that their effort is well directed, for the average native has no interest as to whether his work is productive of results, and the *capitas* frequently seems to share this attitude. Properly organized, excavation in the tropics is not as expensive as elsewhere, per given quantity, but owing to the climatic conditions, there is usually a greater overburden to be removed and a greater depth of decomposed seamy rock to be cut to get a reliable foundation, and interruptions of the work from rain are likely to be more frequent than in more favored climes. Where timber for buildings must be hewn from

MACHINERY AND TIMBERS BEING ASSEMBLED IN YARD BELOW SITE OF COLORADO MILL, APRIL 1911. YARD MADE FROM MATERIAL REMOVED IN EXCAVATING FOR MILL ON THE HILLSIDE.

ERECTING COLORADO MILL. FOREMAN WITH JAPANESE CARPENTERS AND FILIPINO HELPERS.

the forest or whipsawed from logs in the woods, considerable delay may be experienced in getting it out, unless one begins early and keeps eternally after it, and then it is usually not well sized or selected, requiring much extra work on the part of the framers, so, unless it is practicable to put up a sawmill for the job, it is always better to get the timber from outside when possible. Of course, heavy timbers of specially hard and desirable wood for foundations and other limited needs, are often best cut out on the ground.

Whenever it is possible to obtain cement at a reasonable figure, it is always advisable to put in concrete retaining walls and machinery foundations and lower working-floors of the same material. Next in desirability comes cut stone laid with cement mortar. I have even had satisfactory dry stone walls laid by Japanese masons. If timber must

be used, none but hardwood should ever go into foundations or any point in contact with the earth, for not only are vegetable decaying agencies unusually active in the tropics, but the festive *amai* or white ant is likely to get into and destroy any ordinary timber, and more especially pine. I have even known them to enter fairly hard woods, but if these are not in actual contact with wet soil the danger is not great. It is of the utmost importance to keep tankage piled well off the ground, even though it be redwood, for I have known of pine tanks, and sometimes redwood, to be completely ruined while awaiting erection. The supports must be watched and the covered runways of the ants destroyed as soon as begun. A white ant never voluntarily comes out into the light, but a single night will often suffice for ants to build several feet of mud runway up a post to gain access to a pile of timber above. A little coal-oil judiciously applied will act as a preventive of trouble in many cases. It is always safest to have a good supply of building material on hand before getting the framing and erecting force on the ground, so there may be no delays on this score. It should be well sorted and conveniently arranged in a yard ample in size for the carpenters to work without crowding and for storing the framed parts until the actual erection begins. It is best to have every piece of a given building or floor framed, marked, and piled before a start is made, and the bolts should all be out and ready. Then there will be no waiting for pieces when the erection gang starts. For erecting it always pays to provide a good double-drum erecting hoist with plenty of  $\frac{1}{2}$  and  $\frac{5}{8}$ -in. steel cable on the drums, and in addition a liberal supply of new double and triple falls. The rope in these must be renewed very often in the tropics, as hemp deteriorates rapidly in use. The store-house should always have a stock, so that no rope need be used after it has shown signs of weakness. Steel-wire rope is always more dependable than hemp, but it must be well cared for by frequent 'doping' to last well. This applies to all steel and iron in the tropics; they must be protected by paint or grease, or rust will soon destroy them. Chains are not of as much service here as elsewhere for the reason that they are not so easily protected.

The machinery for a mill in the tropics should not be rushed on the ground too early, for it is difficult to protect it properly if it has to be stored outside awaiting erection. It is usually not practicable to unpack machinery until ready to erect, and frequently, on unpacking, it is found in a badly rusted condition. It is a common failing to rush the shipment of a plant unnecessarily, not allowing the manufacturer the time he should have to perfect the shipment, or the men on the ground time to get ready to receive it properly, with the too frequent result that in the hurry of shipment essential details are overlooked, and the man in charge of erection has it in the way for weeks before he needs it. Of course, where there are severe transportation conditions to be considered, it is best not to be behind in getting it off, for it often takes months to get a shipment to the site from the nearest port. As a rule, where water transportation is available, it is not a serious matter to transport machinery, but once the waterway is left, the trouble generally commences. Usually the roads are bad, especially in the rainy season, proper wagons are not to be had, and the draft animal of the country must be used for motive power. In getting the equipment of the Colorado Mining Co., at Aroroy, P. I., from the point of discharge of the lighters, half a mile from the mouth of a tidal river, to the millsite, two miles away, I first built a fair road and surfaced it with gravel, and built a low wagon entirely of hardwood bolted together, the wheels of which were 13 inches in width and 20 inches in diameter, with axles  $5\frac{1}{2}$  inches diameter, the wheels and axles being of *molave*. This, with a string of carabao or water buffalo, in pairs, was sufficient to handle the heaviest pieces (six tons) at the rate of a trip a day. After the first few trips the condition of the road was much improved by the passage

of the broad wheels. The illustrations show this rig with a 100-hp. boiler aboard. The whole shipment was cleaned up in about a month. The cost of the wagon was less than \$250 and it lasted out the job in good shape. Where boilers are the only really heavy portion of the equipment, and the shipment is delivered near the property by sea-going vessels, it is the frequent custom to plug the flues and float them ashore, but this should not be done where it can be avoided, for the reason that it gets sea-water in the seams and less accessible parts of the boiler, and this may cause leaks later on.

The erection of milling machinery in the tropics, as elsewhere, must be entrusted only to a good millwright to get good results. He must have the best mechanical

BUILDING, CONCRETING, AND EXCAVATING SIMULTANEOUSLY.  
COLORADO MILL.

help available, and it is always advisable to have thorough detailed plans prepared before work starts, by some one thoroughly conversant with local conditions as well as the needs of the process and plant being put in. Manufacturers, by realizing the special requirements of shipments to tropical countries, and making an effort to conform to them, can make the lot of the constructor a more happy one. All heavy pieces, and especially pulleys, should be well crated, and all pieces should be well marked with white paint. Tags are no good, as they get wet and fall off. All bearing parts and shafting should be painted, and all threads well oiled. Particular care should be taken that everything is well invoiced and that contents of packages correspond exactly to invoice. As an example of an ideally packed shipment, I recall a consignment received several years since in the Philippines from a well known firm of cyanide supply people of London. Not a single item was missing or a single part broken or injured. The gross weight exceeded the net by over 25%, if I remember correctly, but the satisfaction of getting the machinery in such good shape more than

made up for the additional expense in first cost of packing and freight. While our American machinery exporters are not, as a rule, so painstaking as the English, yet most of them will manage to get shipments off in pretty good shape if they are not too hurried by the purchaser. The trouble is more likely to begin with the arrival in the foreign port, either from over-carriage by steamer, losses in lighterage, in customs, or in trans-shipment to local ports. The people who handle this business are usually unfamiliar with the class of goods and often indifferent to its fate. As an illustration of how a small matter of neglect may affect an enterprise, the 'story of the missing lugs' may be told. A number of years ago a San Francisco firm sent out a small stamp-mill and cyanide plant to an Eastern port and I went out to set it up, arriving on the same boat. After a week consumed in waiting for the parts of the shipment to filter into the customs house it was finally cleared, and I checked it into the train for the provinces and found a shortage of a barrel of patent malleable lugs. I verified this shortage by checking at the railroad terminal, where the shipment was stored until the rains should be over, and reported the shortage to the office of the mining company, received the assurance that it would be looked up, and went out to the mines. Six months later, when the shipment finally arrived at the mines, the lugs were still short, and inquiry only elicited the fact that after sending out a tracer the office had promptly forgotten all about them. After some more delay due to useless correspondence relative to advisability of making the lugs, a cable was sent off, only to arrive in San Francisco during the troublous times of the fire, in which the records of the shippers had been destroyed. When the lugs finally arrived, several months after the rest of the plant was ready for operation, they were of a smaller size than required. They were made to do, however, until another set could be sent for. The last stroke of fate came when, a year later, the original lugs were sold out of the customs house as unclaimed goods.

## Prospecting in Nicaragua

By W. A. CONNELLY

If the two concessions now covering the northern half of Nicaragua be finally cancelled, as the Nicaraguan Government proposes, this will throw open to prospectors one of the most promising gold-bearing areas in the world. Nicaragua can be reached from the United States on the Pacific side from San Francisco and Los Angeles, landing at Amapala or Corinto. On the Atlantic side the route is from New Orleans or New York by fruit boat to Bluefields or Cape Gracias. In going to the northern part of the republic it is more convenient to depart from New Orleans and land at Cape Gracias, at the mouth of the Wanks river. If one is going to the districts on the Banbana, Prinzapulea, Wawa, or Escondido rivers it is better to disembark at Bluefields. Boats leave New Orleans twice each month for Cape Gracias and frequently for Bluefields.

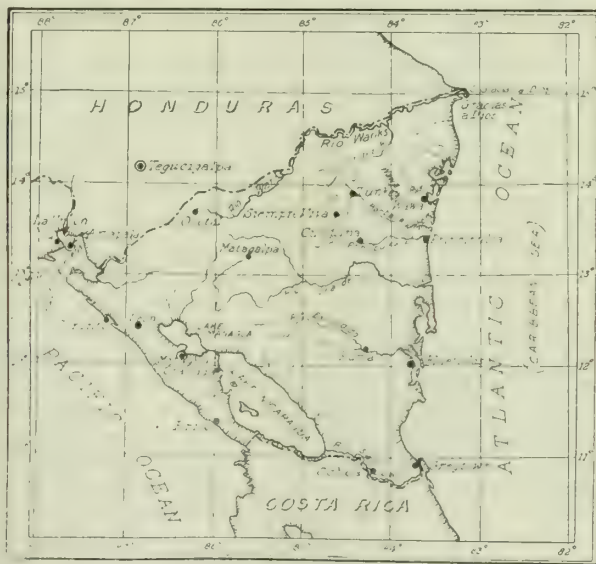

On the Wanks river a large steamer and several gasoline boats ply between Cape Gracias and the mouth of the Waspuc river. To reach the mining districts farther up it is necessary to take *pit-pans* (dug-outs) paddled by Indians. There is always a goodly number of these boats available, as they carry the freight and mail for the Piz-Piz district. There are also steamers on the Escondido river, going as far as Rama, and farther up by *pit-pan*. The first-class passage rate from New Orleans to either Cape Gracias or Bluefields is \$50, and an additional \$50 will cover the expense to any of the various districts from the port.

The trip across the Gulf and Caribbean sea requires four days to the Cape and five days to Bluefields. From Cape Gracias to the nearest mining district takes four days, and from Bluefields to the various camps is three to ten days.

On Wanks river and its tributaries are the following districts: Moribela, Saloon, Umbra or Millers, and the Piz-Piz. On the Banbana and its tributaries are Tunky, Okunwas, and Bana Cruz. On the Prinzapulea is Cuicuina, and on the Escondido is the Rama district.

Before going to Nicaragua on a scouting or prospecting trip the prospector should understand that he must be self-supporting. The operating mines employ only a few white men, and these are usually engaged in the United States and taken to Nicaragua under contract. The labor in the mines is performed by native Spanish, Mosquito Indians, and Grand Cayman Creoles. As this labor can be had at from 50c. to \$1 per day, it leaves little chance for a white man. A prospector should therefore take to Nicaragua sufficient money to finance his trip and to return if he so desires.

The outfit needed for one year's stay is about as follows: 2 pairs of 16-in. waterproof boots; 2 pairs of low shoes, heavy weight; 1 pair puttees; 2 dozen pair socks; 4 suits light-weight wool underwear; 4 suits of light-weight cotton underwear; 2 suits khaki; 2 suits of denim; 2 heavy, wide-brim felt hats; 2 pair double blankets; a pillow;

MAP OF NICARAGUA.

one suit of traveling clothes. These can all be carried in mail bags and this will save taking a trunk. An army cot is very handy. A good revolver with 100 rounds of ammunition should be a part of the outfit. As there is plenty of game, a shotgun is useful, as is also a rifle of small calibre. If a rifle is to be taken in, a special permit must be secured. The list of clothing is given with some detail, since so many prospectors and engineers have gone into Nicaragua carrying much useless clothing or not carrying the right kind. Many of the articles can be purchased in the country, but at a greatly advanced price. A prospector should take along a good compass, a pan, and mortar, also it would be economy to buy his tools in the United States.

Mining machinery and tools may be introduced into the republic free of duty, provided the operator first 'matriculates' with the political chief at the port of entry. This matriculation must be renewed every six months. American currency passes readily anywhere in Nicaragua, and in fact is often at a premium; small denominations are the handiest. No passport is needed, nor does the Government require a permit to allow the prospector to work.

The mining law is not complicated, but the prospector should possess himself of a copy of the English translation upon entering the country. As most Americans entering a Spanish-speaking country will need help in making denouncements and in securing titles, it would be well to retain a lawyer at the port of entry and give him power of attorney to transact all mining business.

This will be only a small item of expense and will be found to be a great convenience.

The best time to prospect on the Atlantic coast is from January to July, although after an American becomes acclimated he pays little attention to the seasons. The following is a record of the rainfall for the year 1910:

	Inches.		Inches.
January .....	8.73	July .....	20.56
February .....	8.21	August .....	14.08
March .....	3.98	September .....	14.06
April .....	5.87	October .....	12.79
May .....	8.85	November .....	9.19
June .....	17.45	December .....	10.46

It will be seen that the rainfall is greatest in July. While June of this particular year had 17.45 in. of rain, it is usually dry until late in the month. The greatest rainfall in any one year was in 1908, amounting to 145.61 in. The record from which this was taken had been kept for seven years. The prospector will always have a few months of delightful weather in which to do his scouting and selection of a place where he may do development work during the rainy season. From the record of rainfall it will be seen that a prospector need never worry about a supply of water.

Upon reaching the particular district decided on, the prospector should select a site on sloping ground and prepare a permanent camp. A clearing should be made and a bungalow built. A bungalow is a simple affair and can be built in a few days at a small cost. The only ironwork needed is a few nails and a pair of hinges. The natives will build a fair-sized house on contract for 100 *soles*, which is about \$40 gold. From the main camp area enough for a season's work can be reached, and if it is desired to go farther afield in scouting for veins, a shelter for the night can be built in an hour.

The whole country is covered with tropical vegetation, and at first sight it appears to the newcomer to be a hopeless task to find anything in such a jungle, but prospecting is much easier in Nicaragua than in many parts of the Rocky Mountains. The country rock on the Atlantic slope is eruptive and generally supposed to be andesite. This andesite is easily weathered and eroded. The vein filling is quartz and pyrite, and erodes more slowly than the enclosing country rock, consequently the veins outcrop. The veins may be said to always have a *manta* or covering of broken and eroded ore which has been enriched by a process of mechanical concentration. Float is plentiful near all veins, and the prospector need only follow up one of the numerous creeks, watch for the float, and the vein will soon be discovered.

In tramping across country it is always advisable to have a guide. Former cutters of rubber are plentiful and can be had by the day for 2 *soles* and board. These men know the 'bush' well and are absolutely reliable. They will do any kind of work, are intelligent, often have a good knowledge of mining, and will gladly show an employer veins discovered in the course of rubber-cutting trips. In scouting over the country and in going to and from the base of supplies, a mule, saddle, and bridle are necessary. The mule can be purchased in the country for 150 to 200 *soles*, but the saddle and bridle had better be bought in the United States. The McClellan tree saddle is the one most generally used in the tropics.

The freighting is done with oxen, either 'pack' or 'drag.' Because of the high tariff, foreign foodstuff is much more expensive than in the Western United States, although never as high as in Alaska in the early days. The prospector will soon become accustomed to the use of native-grown food. The more common vegetables include plantain, cassava, yams, sweet potatoes, beans, and corn. The fruits are bananas, pineapples, limes, citronella, oranges, and papaya.

Nicaragua has an area of about 48,000 square miles, and I think that at least one-third of this territory will be found to be gold-bearing. There are more than twenty districts now in which there is machinery and which are

producing gold. In many others pay-ore has been discovered and more or less developed. These districts are in the mountainous part of the country from the Honduras line to La Libertad, west of Bluefields. Because the country rock is altered from 100 to 200 ft. deep, and the veins outcrop, prospecting is easy and early development is cheap. The *manta* is usually soft and easy to mine and mill. Huntington mills are used in many districts, as their first cost is low, they may be sectionalized and quickly erected, and are not extremely heavy. Waterfalls are plentiful on the Atlantic coast, and hydro-electric power plants have been built in the older districts. Power can be bought at a cheaper rate in these districts than in Nevada.

The ore in the districts of eastern Nicaragua is free milling in the oxidized zone, and can be cyanided. While the ore is not of high grade, ranging from \$6 to \$20, with an occasional body of richer ore, the cost of operating is low and will be much lower when transportation is bettered. Nicaragua's great gold-bearing area, everlasting summer, plentiful supply of water, timber, fruit, and vegetables, comparatively cheap labor, simple mining laws, and accessibility, should be very attractive to prospectors.

## American Smelting & Refining Company

For the half-year ended June 30 the American Smelting & Refining Co. reports that the gross income was \$7,587,943, of which \$5,759,729 came from smelting and refining plants. The net income, after deducting \$1,209,817 for depreciation and amortization of property, and certain other appropriations, amounted to \$5,868,958. Interest, and dividends on preferred stock totaled \$3,485,000, leaving a net income of \$2,383,958. Out of this a dividend of \$1,000,000 was paid on the common stock. The surplus for the term was \$1,268,301; and total surplus at June 30, \$14,968,027. On the new smelting plant at Hayden, in Arizona, there was spent \$1,076,649, making the total of \$1,622,692. The plant was blown in on May 29, and profits from it should accrue with the last half of the present fiscal year. On the refineries at Perth Amboy and Baltimore, \$589,466 was spent; and \$106,849 in developing mines owned by the companies. The period covered by the report has been one of great unrest in the labor market, and the Perth Amboy, Baltimore, and Murray plants have suffered therefrom. The strife in Mexico has considerably hampered operations in the Republic; but fortunately the company was not forced to close any of its smelting plants, and but a few mines.

SEIGNIORAGE, or the profit which has accrued to the Government from the coinage of silver, nickel, and bronze pieces during the last 40 years, has amounted to \$205,385,272, according to the September circular of the National City Bank of New York. The cost of copper, from which cents are made, is now about 18c. per pound, and from each pound is coined 146 1-cent pieces. The cost of nickel, from which 5-cent pieces are made, is 33.85c. per pound, each pound being equivalent to 90 coined nickels. Thus the Government realizes about \$4.50 on an expenditure of less than 34c. Fine silver is now quoted at 60 to 61c. per ounce and yields \$1.38 in coin. The coinage of gold has entailed a small loss. A gold dollar contains 25.8 grains of standard gold, of which 10% is copper alloy. To depositors of gold bullion the Government pays \$20.67 per ounce of fine gold, but makes a charge against the depositor of 2c. per ounce for the cost of the alloy used. The Treasury Department has now in its vaults gold coin and bullion to a greater value than ever before in its history, and nearly double that of any of the great foreign nations. The total gold in the Treasury on August 23, 1912, was \$1,221,169,327, of which \$1,008,197,179 was in gold coin and nearly \$213,000,000 in bullion. Of the total, \$150,000,000 is held for the redemption of United States notes and treasury notes of 1890, and \$1,047,568,269 is held for the redemption of gold certificates outstanding.

## Step-Bearing for Slime Agitator

By DOUGLAS WATERMAN

The accompanying drawing shows an excellent form of step-bearing for mechanical slime-agitators in use at the Butters Salvador Mines, Ltd. Air-agitation for the treatment of slime is being widely adopted in the more recently constructed cyanide plants, but it would not always be good policy for an old plant equipped with mechanical agitators to make such a radical change in the treatment as the introduction of air-agitation would require. Moreover, the mechanical agitator still has many advocates among cyanide operators, and it will probably never be entirely supplanted by other methods. There is no doubt that it is an effective form of slime agitator. The chief complaint has been the high power-consumption due to

## Mines in Southern Spain

By EDWARD J. NORTON

From the days of the Phenicians, the first to discover its metallic wealth, eastern Andalusia has been a mining district. The remains of many old workings, some of them celebrated in antiquity for their lead and iron deposits, are still traceable in different parts of the three provinces; and one or two of the ancient shafts and adits, reopened after the passing centuries, are producing ore today. Although many new claims are being filed, few mines are operating now on a large scale. Foreigners—French, Belgians, British, and Germans—control most of the best producing properties of the district, as Andalusian capitalists have always been unwilling to invest money in mining. A great deal of money goes out of Spain on this

AIR-SEALED BEARING FOR MECHANICAL AGITATOR.

the friction in the submerged step-bearing, and the excessive wear in the bearing itself, necessitating constant repairs and renewals. These objections have been largely overcome in a step-bearing devised by W. G. Mosher at San Sebastian. I had an opportunity of examining a bearing that had been in constant use for three years without requiring the slightest attention. While the exterior of the revolving parts was worn fully 1/2 in. smaller than its original diameter by the continued attrition of the pulp, the interior faces were in perfect condition, even the tool-marks being still visible. Only the buttons were worn at the point of contact, but not enough to materially increase the friction. Its form suggests the well known principle of the inverted tumbler in a basin of water, the air entrapped within the cap preventing the rise of the pulp within the annular space around the stem. As an extra precaution against the entrance of the pulp, a sufficient quantity of mercury was introduced to effectually seal the air-space, but it is doubtful whether this is necessary. The two convex faces of the steel buttons form a contact of small area, even after considerable wear, and the power required to overcome the friction is low. It will be noted that the cap is secured to the foot of the shaft by means of the detachable collar. Thus the whole bearing can be removed and replaced without raising the shaft; a distinct advantage. It only remains to add that this device is not patented, and can be turned out by any foundry at small expense.

account, because the greater part of the ores are smelted abroad and the material goes to build up the metal industries of other countries. The total registered ore-bearing acreage, number of working mines, and the producing acreage of the three provinces, according to the latest official reports, is distributed as follows:

Province.	Acreage registered.	Producing Mines.	Acreage.
Ahneria .....	88,753	101	4,222
Malaga .....	16,706	28	306
Granada .....	48,854	20	1,368

The value of ore extracted from these mines annually represents approximately 3% of the total of Spain's mineral output. In the province of Almeria claims have been filed on 1533 properties containing iron ore and 808 claims covering properties carrying lead. In this province are also deposits of sulphur, zinc, and quicksilver. Claims filed in Granada cover 50 deposits of quicksilver, 2 of placer gold, 53 of zinc, 514 of iron, and 174 of lead. Coal, cobalt, and quartz-bearing gold have also been found in this province. The mining register of Malaga shows 175 claims filed covering iron mines, 19 of lead, and 23 of copper. Deposits of nickel and coal are known to exist in Malaga, but no effort has been made to bring them into production.—*Daily Consular and Trade Reports.*

THE Elmore vacuum plant, at the mines of the Sulitelma company, Norway, produced 787 tons of copper concentrate during August 1912, according to a company report.

## Metal Mine Production of California

The mine output of gold, silver, copper, lead, and zinc in California in 1911, according to Charles G. Yale, of the United States Geological Survey, was valued at \$25,174,677, a decrease of \$1,845,728 from the corresponding value for 1910, although the production for 1910 included no zinc. The total decrease was due mainly to a curtailment in the output of copper because of litigation over smelter fume.

The mine production of gold in 1911 was \$19,738,908, an increase of \$23,468. The output of silver was 1,270,445 fine ounces, valued at \$673,336, a decrease of 569,640 oz. in quantity and of \$320,310 in value. The production of copper was 36,316,136 lb., valued at \$4,539,517, a decrease of 12,384,620 lb. in quantity and of \$1,645,479 in value. The output of lead was 1,398,111 lb., valued at \$62,915, a decrease of 1,472,866 lb. and \$63,408. The output of zinc, however, none of which was produced in 1910, was 2,807,035 lb., valued at \$160,001.

There were 1181 properties reported productive in 1911, of which 596 were deep mines and 585 were placers of various kinds. This shows a total increase of 102 producing mines for 1911. There were 522 gold mines producing, 11 silver mines, 31 silver-lead mines, and 30 copper mines in 1911. Of the placer producers, 169 were hydraulic properties, 65 were dredges, 141 were drift mines in ancient river gravels, and 210 were surface or sluicing mines. The dredges were operated by 34 companies, against 41 in 1910.

There were 81 more deep mines and 21 more placers producing in 1911 than in 1910.

The deep mines of California produced 2,944,188 tons of ore in 1911, an increase of 246,303 tons. Of this output 2,443,274 tons was silicious ore (an increase of 479,978 tons), 494,281 tons copper ore (a decrease of 222,404 tons), 2008 tons lead ore, and 4625 tons zinc ore.

The total average value for all ore sold or treated in 1911 was \$5.49 per ton, against \$6.71 in 1910. At gold and silver mills in California in 1911 the tonnage milled was 2,156,950 short tons, yielding \$9,709,331 in gold and 172,855 oz. of silver, or a total average value of \$4.54 per ton, against \$5.25 in 1910. Of this average value, \$3.59 per ton was recovered as bullion in the mills in 1911. The smelting ores, 538,214 tons, produced all the copper and zinc, practically all the lead, 1,004,472 oz. of silver, and \$641,495 in gold. There was also 249,024 tons of old and new tailing treated in California in 1911, yielding \$401,555 in gold and 57,577 oz. of silver.

The placers of California yielded \$8,986,527 in gold and 39,541 oz. of silver in 1911, an increase of \$96,087 in total value over the yield for 1910. The dredges showed an increase in production of \$116,207, and the hydraulic mines an increase of \$39,988, but the output from drift and sluice mines decreased. The dredges produced 38.84% of the gold output of the state in 1911. The total dredge output of California from 1899, when the production from this source began and was only \$206,302, to the end of 1911 has been \$47,985,236. The following table shows the mine output of California by counties in 1911.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN CALIFORNIA IN 1911

[By Charles G. Yale, United States Geological Survey.]

County.	Ore treated.	Gold. <sup>a</sup>	Silver.	Copper.	Lead.	Total value.
	Tons.		Fine ounces.	Pounds.	Pounds.

<sup>a</sup> Includes placer production.

<sup>b</sup> Includes only gold recovered by dredging in these counties; other output of Shasta and Trinity Counties given below.

<sup>c</sup> Includes value of 2,807,035 pounds of zinc.

## Manganese in the Philippines

Manganese ore has been discovered in the Philippines, according to the Bureau of Science at Manila. But since an export wharfage charge exists on all ore, development is retarded. If the ore were taken in ballast to Japan, this charge would not be serious, but if it were shipped to the west coast of America, the freight rate would reduce profits to the vanishing point. The same is true in regard to iron ore. A geologist from Japan, in the employ of the Mitsui Bussan Kaisha, examined the iron deposits on a small island in Mambulao bay in Ambos Camarines, where iron ore occurs, but the royalty to be paid to the persons owning the land and the export dues would leave little for the expenses of mining and the profit. It is recommended that as soon as possible the law be altered, remitting these export dues.

## Mineral Discoveries in Arabia

An Indian business man recently completed an extended prospecting tour of Oman at the instance of the Sultan. Only surface work was attempted, and it was found impracticable to visit the coal beds which are said to exist in the Sharkeyah district, but it is reported that a valuable chromium deposit, containing small percentages of lead and silver, was found about four miles from Sib, and that development will soon be undertaken. Tentative plans involve building a 30-mile tramway from Matrah to Sib.—Consular report by Homer Brett, Maskat.

NITRATE production in Chile for the year ended June 30, 1912, exceeded the consumption by 1,227,947 Spanish quintals, of 101.4 lb. each. The farmers of Chile used five times as much nitrate for fertilizer in 1911 as in 1908.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Persistence of Ore in Depth

The Editor:

Sir—In T. A. Rickard's interesting article, under the above heading, in the *Mining and Scientific Press* of August 31, he says, "the miner has experience to justify him in his fancy that water is a favorable indication of ore." This reminds me of one little point noted at Kalgoorlie. The majority of the mines on the 'Golden Mile' are comparatively dry, those on the eastern side being the wettest; not many have to pump or hoist over a few thousand gallons daily. Just out of this area, and all around it, are mines which produce a great deal of water, having in the past supplied many mills. These outside mines have produced little ore, and have been opened fairly well. All water in this district is very salty. At the 1909 meeting of the Australian I. M. E. at Kalgoorlie, A. Montgomery said that the salt water was caused by the country being under the sea at one time; while J. M. Maclaren argued that the arid nature of the country would easily account for it.

M. W. VON BERNEWITZ.

San Francisco, September 4.

The Editor:

Sir—It affords me no little pleasure to read my friend T. A. Rickard's views on 'Persistence of Ore in Depth,' published in your issues of August 24 and 31, and to find his ideas upon this interesting and important subject in close accord with my own. My paper upon the subject, read at the recent Toronto meeting of the Canadian Mining Institute, was designed for the purpose of eliciting opinions and provoking a discussion that would be of practical value to the mining industry. I realized then, as I do now, I have little that is original and which throws light upon the subject, but it is worth an effort and may serve a useful purpose to collate whatever data can be found relating to the subject.

In the United States at least, we are rapidly approaching a period when we will have to seriously consider the exhaustion of our metalliferous deposits; it has been evident for some time that new discoveries are not equaling the depletion of those already developed, and the question arises, is it not likely that districts supposedly exhausted are in fact often not so, but might readily yield new sources of mineral wealth as the result of scientific prospecting? We all know that to a limited extent this general principle has been demonstrated in some instances, but often the exploratory work does not go far enough, being apt to be limited by preconceived notions and theories, lack of funds, and the admitted tendency of ore-bodies to become leaner with depth. I refer, of course, to quite modern conditions. Years ago water was a great deterrent in deep workings, now it is an obstacle readily overcome; in fact, as will be later explained, it may be regarded as a welcome guest.

A few old districts have a way of pegging along with a small annual production squeezed from dumps and abandoned stopes; others are completely abandoned, to be reopened at a later period or not at all. Now that development and underground prospecting are more systematically pursued, the total abandonment of a lode or even a district before exhaustion would seem to be less likely. The difficulty is to determine for certain when a deposit or lode has been finally bottomed and further prospecting hopeless.

It may be accepted as a broad and general principle that all mineral deposits or lodes of whatever character decrease in richness with depth. I do not believe this

dictum can be successfully controverted, although there may be some temporary and apparent exceptions; but even these in the end will doubtless be found to conform to the general rule. Conceding this, or in other words that mineralized fissures cannot extend indefinitely toward the interior of the earth, the point is to determine approximately where the limit of profitable ore may be expected. For the sake of illustration, let us suppose two lodes to have originally contained ore to a vertical depth of 5000 ft. and of practically the same value in each instance. During the geologic period subsequent to their deposition one has had 4000 ft. eroded off and the other say 500 ft.; now when they have been both worked out or bottomed, it may be said one 'petered out' at 1000 ft., while the other persisted to 4500 ft. before exhaustion. In drawing such a conclusion we would thus fail to recognize that there remained, at the time the lodes were developed, in one case but a stump and in the other pretty much the whole vein. As a matter of fact, we cannot ever hope to know exactly how much has been lost by erosion, but we can arrive at some approximation of it by a thorough study of the local geology. I have in mind two famous mining districts about 150 miles apart, one of which has had from 2500 to 3000 ft. removed by erosion, whereas the other has lost in that manner comparatively nothing; if, on the contrary, the latter had suffered an equal amount of erosion, its 2500-ft. level would be about at the outcrop of the lodes in the eroded district and its greatest riches would have been lost because they occurred above the 2000-ft. level. While it is idle to discuss what a lode might have been had it not been subjected to erosion, it is important to determine the extent and depth of this degradation because, assuming that mineral fissures were not likely to have originally extended deeper than 6000 to 7000 ft., we would know that if 3000 to 4000 ft. had been lost by erosion our probable existing ore limits would be at depths not exceeding 3000 ft. I suppose in the majority of cases original lodes or veins ended at depths much less than 6000 or 7000 ft., and that is the reason why in areas which have suffered tremendous erosion, like the gold district of Nova Scotia, the Cobalt region in Ontario, and our Southern Appalachians, the deposits as we now find them are shallow and often too lean to be profitable except in a comparatively few instances where modified by secondary enrichment.

It is well known that deep mines tend to become progressively dry with depth, this fact cannot be successfully disputed, and it may be assumed as a general rule that the amount of deep aqueous flow is directly proportional to the extent of fissuring, in other words, fissures are a prerequisite to water circulation. But it will be said there are some deep mines in which the inflow of water has not naturally decreased, but rather increased. Such cases are, doubtless, exceptional, and probably if the workings be carried deep enough the rule will be found to hold.

It is reasonable to assume that wherever there is deep fissuring through and by which at one time there had been active aqueous or vaporous circulation, some of the fissures have become more or less filled with mineral depositions. Hence, if we assume that a strong flow of water at deep levels is an evidence of fissuring, we are justified in concluding some of these fissures may contain ore, and that deeper exploration under such circumstances is warranted. Of course in applying this reasoning to any particular case the mining engineer must be guided by his experience and sound knowledge of the principles of ore deposition, since it cannot be assumed that simply because there is a copious flow in the deep levels, one is certain or even likely to find ore. It is, however, to my notion, a good sign in cases where rich ore has been found on higher levels. We know from experience in tunneling and shaft-sinking for other than mining purposes that mineralization does not accompany fissuring in a country not affording the necessary conditions for ore accumulation and deposition. Again, fissuring and mineralization may be found unaccompanied by any aqueous flow, as in desert regions, but they are undoubtedly indicative of conditions which once existed; if

we are to accept the hypothesis that primary ore deposition, with the exception of magnetic segregation, must be the result of aqueous and vaporous circulation.

In conclusion, I would again emphasize the desirability of ascertaining in all cases where deep exploration is contemplated, the amount of erosion the district has suffered. As we are not likely to have to decide such questions except in regions which have been studied and geologically mapped, there need be no great difficulty in determining the extent of such erosion within approximate limits. Obviously, no exactitude can be expected in such instances, for mathematical deductions as applied to geology must of necessity be of a most general character.

F. LYNWOOD GARRISON.

Andover, Massachusetts, September 6.

### Foreign Trade and Panama Canal Tolls

The Editor:

Sir—Having learned during the days of T. A. Rickard to look to the *Mining and Scientific Press* for editorial comments untainted by special interest, I should very much regret to think that Mr. Ross had frightened you by his protest from your disposition to refer to vital matters not obviously connected with mining. In San Francisco there are few disinterested publications which are able, owing to their affiliations, to take an intermediate position between the defense of privilege and the defense of criminals. A point of view that coincides with that of a trained political economist, as Mr. Ross points out, is very welcome to such of us as have to depend for our colored political views, and our no less colored news of California mining operations, upon one of the San Francisco morning papers; and at evening time, have to imbibe the half-warm mixture of morality and tears, served up by one of the evening papers, if we cannot stomach the portion offered by the other.

The point at issue between yourself and Mr. De Kalb appears to me to be the fundamental difference between the advocates of democracy and the advocates of autocracy; between equity and strength; between privilege and equal opportunity; between the free trader and the protectionist; between radical and conservative; and between the motive force and the brake. The difference is almost as fundamental as the difference in sex. As a contribution to the discussion, I would suggest that the commercial neutralization of the canal is imposed upon the United States, quite apart from the treaty, by the Monroe doctrine, under cover of which we took from Colombia what we would not suffer anyone else to take. In addition to this, it would be well to realize the underlying motive of the Canal bill. The admission of foreign-built vessels to American registry; and the remission of tolls to vessels engaged in the coastwise trade are both only disguised forms of ship subsidy; and ship subsidies are desired by certain interests to offset the logical consequences of protection. This attempt 'to get the consumer both coming and going' has been a failure up to the signing of the Canal bill; but it seems to have been quietly accomplished at last. The unnatural exhaustion of natural resources, the passing of the merchant marine, the tendency toward merciless monopoly, and the alleged lack of interest in efficiency; these are all the degenerate children of protection, and nurse them as we may with conservation, ship subsidy, Sherman anti-trust laws, and the new efficiency, they will remain to cause us trouble until we get rid of the author of their being. The whole underlying motive of the Canal bill is ship subsidy; but the consumer who pays the bill has not yet been definitely informed.

In Downieville, to return to mining matters (as a concession to Mr. Ross), there lives a ne'er-do-well, a hard-drinking brother of a San Francisco merchant, who was sent up to be as far from his family as possible. He was subsidized for the sake of peace, but was not allowed any cash. Food, tools, and clothes were provided by the storekeeper, and the bills were duly honored in San Francisco.

The old craving eventually overcame the outcast, and he repaired to the store, after studying the limitations of his treaty. To the storekeeper, he said briefly, "A quart of Scotch, please, and charge it to picks."

DAVID AMINS.

San Francisco, September 5.

The Editor:

Sir—One object in sending you the editorial from *The Public* was to show you how a 'trained political economist' could carry out the engineering maxim of getting the 'maximum results in the minimum space.' As the trained economist and yourself agreed, there was a chance to determine the question of 'saved space.'

Your statement of the Mother Lode is perfectly true: "In our judgment, fortified by that of several of the best experts who have studied the Lode in the past two years, the Mother Lode district today affords one of the best opportunities in the world for the development of profitable deep gold mining." As a trained mining engineer and economic geologist who has the respect and confidence of his professional brethren and of the general public who are interested in mining, can you, Mr. Editor, think of a better or more worthy task than to help reduce the development of the Mother Lode mines to a sane business system? Get the mines and owners together. Show them the follies of the petty jealousies; the good that can result from the exchange of experience; the value of correct surveys; the full meaning of economic geology; tell them how easily they could combine in each district and secure the services of such a geologist, and show them from any of a dozen instances that are well known, what the particular instance could easily have been made had such advice been secured and acted upon. Show them the folly of a continued belief in their so-called secrets—business and professional—if they would but take time to look above the edges of the grooves they have dug for themselves they could hear the little children of their district using the terms of their deepest secrets in their play. Our good friends along the Mother Lode have so profound a belief in their secrets that the wayfarer is assured that if he has not heard one of the richest and best known Mother Lode operators tell the story of how completely he has exhausted his ore reserves and how utterly worthless the lower levels of his mines are, and how the fear of approaching poverty destroys the pleasure that he might otherwise get of a view of the happy and beautiful homes that surround him—if he has not heard all or part of this story, he has missed a rare treat. Show them how to keep correct mining and milling accounts and how they deceive themselves in their cost sheets. Many of these mines are owned largely by the public, and there is no excuse for any sort of secrecy in their accounts, and my dear Mr. Editor, if you do all or part of this for California and have then time and space for general economics, we will club together in some way and help you secure the services of a 'trained political economist,' who will give us, while treating such subjects, 'the maximum results with the minimum of effort.'

G. McM. Ross.

Stockton, California, September 1.

[It must have been a 'trained political economist' who condensed into one aphorism the much that might be said as to the excellent plan proposed by our correspondent for publicity along the Mother Lode—"You can lead a horse to water, but you can't make him drink."—EDITOR.]

Gold yield of Victoria, Australia, for July 1912 amounted to 36,733 oz. gross, or 33,880 oz. fine, valued at £143,914. Compared with the yield for July of last year a decrease of 11,060 oz. fine has occurred. The yield for the last seven months was 282,688 oz. gross, or 262,015 oz. fine, valued at £1,112,322. This shows a decrease of 26,280 oz. fine compared with the quantity produced during the corresponding period of last year.

## Special Correspondence

### NEW YORK

ALASKA GOLD MINES.—THE SHARE MARKET.—COPPER SURPLUS A MINIMUM.—A NEW CANADIAN BOOM.

The properties on Douglas island and the neighboring mainland are receiving an added share of attention, owing to the recent promotion of the Alaska Gold Mines Co. by the Guggenheim interests, and what is being accomplished by other neighboring properties is of especial interest to the public at the moment. The most important neighbor of the new company is Alaska Treadwell, whose report for July, together with that of the Alaska United and the Alaska Mexican was given in the August 3 and 10 issues of the *Mining and Scientific Press*.

The spectacular feature of the week's news in a market way was the apparently final collapse of the market in the shares of the U. S. Motors Co. This corporation has long been counted as one of the leading automobile concerns in the United States, and has always been looked upon as having been fathered, at least indirectly, by J. P. Morgan & Co. On the announcement that the company would be thrown into bankruptcy, the shares declined to nominal prices, and apparently another industrial has 'blown up.' Industrial issues have been in great favor marketwise recently, and the public is about to learn that such securities must be analyzed just as closely as mining issues. In mining circles the most important incident was the publication of the report of the Copper Producers Association covering the month of August. The huge production of the refineries might be considered a good argument for those who have been bearish on the copper situation, as justifying the predictions of a tremendously increased output. The output of 145,628,521 lb. breaks all records for any single month in the history of copper mining in the United States. The July output was a record breaker, but August bettered July figures by nearly 8,500,000 lb., and of even more significance was the record-breaking take-up of copper metal, domestic deliveries amounting to 78,722,418 lb.—more copper than was ever taken in any one month by domestic consumers, and nearly 600,000 lb. greater than the previous past record made in January 1910. Exports were 70,485,150 lb., which is not a record breaker. Another broken record is the figure for the surplus stocks on hand September 1, the surplus being 46,710,374 lb., an amount of copper on hand that will justify further efforts to increase production. The entire copper situation becomes very interesting. The natural question arises, is the present production the maximum for the new copper which has been talked about for so many months, or will it continue to increase, and in either event will deliveries continue to take care of the present or even a greater output? The present surplus is not even as large as the nominal trade conditions demand in the way of a balance; but it is undoubtedly true that consumers, if they could see production creeping up month by month, would immediately begin to refuse to carry copper stocks, especially at present prices, and this is true even though the present low surplus is far from any figure where it threatens to be a serious factor in the metal market. The most perverse factor in the situation is the fact that leading copper shares have diminished in price, in the face of greatly increased production at much higher prices. It is quite evident that traders in copper shares are inclined to discount the future a long way ahead.

The Kornkob Mining Co. has made its appearance in New York markets; the property is near Tucson, Arizona. Recent despatches state that good copper ore has been found at a depth of 350 feet.

W. C. Brown, president of the New York Central railway, has returned to New York after a protracted vacation, during which he traveled some 10,000 miles, spending eleven days in Alaska in the vicinity of Ketchikan,

Wrangell, Juneau, Douglas, Skagway, and Sitka. Mr. Brown says: "The mining interests everywhere, representing copper, gold, and silver, are prosperous and there is great activity in the way of prospecting and new development. This is especially true in the neighborhood of Juneau and in the valleys southeast of Skagway."

The Hollinger mine at Poreupine is reported to have produced \$200,000 in gold during the month of August, and is said to have enough ore developed to maintain this rate of production for the rest of this year, when further mill capacity will be provided and production increased.

Some of the Eastern newspapers are predicting a revival in Cobalt, showing that a great boom, founded on real mining results, is about to be sprung upon the public. Telegraphic despatches state that within the past few days some silver-bearing ground, similar to that which has yielded so much in Cobalt, has been found in the township of Auld, some twelve miles from Cobalt.

The discontented minority in the Stewart Mining Co. were unable to make any headway against the Heinze forces, and an entirely new board of directors was named by the majority, consisting of Edward Hickey of Butte, who is president of the Tuolumne Copper Co., W. E. Cullen of Spokane, A. X. Bowie of Butte, and W. O. Allison of New York. W. A. Beaudry is resident director and mine manager. Mr. Allison is president of the National Reserve bank.

### LONDON

NEWS FROM CORNWALL.—IMPROVED RESULTS AT DOLCOATH, CARN BREA & TINCROFT, AND GRENVILLE.—HOLMAN STAMPS.

The half-yearly statements issued by the leading Cornish tin mines are of unusual interest, for three of them, Dolcoath, Carn Brea & Tincroft, and Grenville, show improved results due both to the high price of tin and to more

energetic development. The report of Dolcoath for the first six months of 1912 shows that, as compared with the second half of 1911, the amount of ore raised was 2223 tons greater, the yield of black tin per ton 4½ lb. less, and the average price received £7 2s. 1d. per ton more. The sales of tin concentrate realized £97,730 as compared with £98,647, and the profit was £32,538 as compared with £35,581, so that the varying factors were fairly well equalized in the results. The tonnage crushed was 48,566, the black tin sold 796 tons, the yield per ton 36.73 lb., worth 40s. 2d., and the average price per ton £122 14s. 7d. Other items of revenue brought the total income to £100,428 or 41s. 4d. per ton. The working cost was £61,375 or 25s. 3d. per ton, and the lord's royalties £6515 or 2s. 8d. per ton, making a total cost per ton of 27s. 11d. The profit, as already recorded, was £32,538 or 13s. 5d. per ton. Out of the profit £4594 has been written off on plant, and £17,225 was paid as dividend, being at the rate of 15% per year. During the half-year, four more 'air-cushion' stamps have been erected, thus completing the new installation of 12 stamps; during the current half-year the output of the mill will be thereby increased.

In the early part of 1912 the floods interfered with the working of the lower levels, and made it impossible to increase the output to the capacity of the enlarged mill. For several months the old Cornish pumping-plant was used in conjunction with the new electric plant. Since the beginning of June the latter has handled all the water by itself and has given every satisfaction. The coal strike was responsible for a curtailment of development work, 1881 ft. being done, as compared with 2076 ft. during the previous half-year. A new compressor for 20 drills is being erected at the Williams shaft, and when it is completed it will be possible to increase the amount of development done. The ore disclosed during the last year or so has not been up to the average of recent years, so it is gratifying to find from R. Arthur Thomas' report that richer ground, averaging 56 lb. black tin per ton, has been found on the 490-fm. level. At the meeting of shareholders held September 3, Mr. Thomas had the pleasing duty to announce that on this level the last 72 ft. driven had been in ore averaging 100 lb. of black tin per ton. He also announced that a further four heads of air-cushion stamps were to be erected.

The report of the Carn Brea & Tincroft for the same period shows that 45,444 tons of ore was raised, and that 482 tons of tin concentrate was recovered. The tonnage of ore was the largest on record, comparing with the previous highest, 41,674 tons, during the latter half of 1911. The output of concentrate is not so high as during the half-year January to June 1909, when 568 tons was obtained from 36,825 tons of ore. The yield per ton was 23.79 lb. black tin during the last half-year, figures not much different from those of the previous two half-years. On the other hand, the income from the sale of concentrate was easily a record at £56,096, owing to the present high price of the metal. The average price received per ton of concentrate was £116, as compared with £69 for January to June 1909, when the record output of concentrate was made. The sale of tungsten and arsenic, together with other small items of revenue, brought the total income to £58,725. The working cost was £53,434, again a record figure, comparing with the previous highest, £47,504, during the preceding half-year, the rise being chiefly due to the greater amount of ore treated, but partly also to the greater cost of pumping and of new plant. The above figures include lord's royalties of £2129. The total cost per ton was 23s. 6d. as compared with 22s. 9½d. during the previous half-year. The net profit was £7321, and, deducting the adverse balance, £6017, brought forward from the previous half-year, the credit balance on June 30 was £1102. E. S. King, the manager, gives an outline of the developments during the period under review. Of these, the most important is the cutting of Dunkin's lode on the 335-fm. level, as it promises to provide a large amount of good-quality ore. Also a new lode containing ore of more than average grade has been found in a cross-cut on the 160-fm. level in the High-burrow East section.

It will be remembered that the Grenville United company was formed in the summer of 1906 under the limited liability laws, to acquire the Grenville tin mine, situated to the south of Camborne, that had previously been worked for many years on the cost-book system. A year ago I mentioned that the new manager, Henry Battens, had introduced many reforms and improvements, both in the method of buying supplies and in the development and treatment of the ore. The report for the half-year January to June shows that 20,166 tons of ore was hoisted, and 369 tons of tin concentrate recovered, being a yield of 41 lb. black tin per ton. The figures for the previous half-year were 19,306 tons of ore, 331 tons of concentrate, and 38 lb. per ton. The concentrate was sold for £47,012, being at the average rate of £127; this high price is obtained on account of the exceptional purity of the product. The profit was £17,295, out of which £3501 was paid as lord's royalty, and £13,912 as dividend, being at the rate of 40% per year. In May last a call was made of 2s. 6d.

on the 49,730 shares of 10s. each, on which only 2s. 6d. had hitherto been paid. The capital now consists of 130,270 shares of 10s. fully paid, and 49,730 shares 5s. paid. During the half-year, development was retarded by the coal strike, but such work as was done gave gratifying results at many points, especially in the 355-fm. level east of Fortescue's shaft. Mr. Battens is pursuing a decidedly vigorous policy of development and is erecting additional re-grinding and dressing plant.

## TORONTO, CANADA

HOLLINGER AND DOME RETURNS.—LA ROSE AFFAIRS.—NIPISSING PRODUCTION.

The output of the Hollinger mine, Porcupine, for August is given as approximately \$200,000, of which \$110,000 was recovered in the last 13 days of the month. The production of the Dome for the first week of September is reported at \$43,000. The Vipond is still struggling against difficulties, due to a shortage of the water supply and the plate area being too small. The latter trouble is being remedied by addition of three additional plates, which will make eleven in all. Meanwhile, only low-grade ore is being treated. Development at depth, at the McIntyre, has revealed a considerable change in the character of the ore, which at the 300-ft. level has become rich in sulphides carrying very fine gold. This has rendered necessary a change in treatment. The plans now being prepared for the extensions of the mill, provide for a cyanide plant, and will probably include abandoning the amalgamating process used for the free-milling ore, extracted from the upper levels. Owing to the discoveries at the McIntyre, the character of the milling plant to be put in at the McEneaney will not be definitely settled until the 400-ft. level is reached, and the vein opened at that depth. The shaft is now down 370 ft. Foundations will be built for a 10-stamp mill, but only 5 stamps will be erected at present. The dump contains 3000 tons of ore worth \$20 per ton. The ore-shoot on the 200-ft. level has been opened, and proved to have a good gold content for over 400 ft. The Hughes has picked up its vein at the 150-ft. level, about 50 ft. from the shaft, where it is 8 ft. wide, and richer than on the upper levels. The shaft will be put down to 200 ft. before developing the vein. Plans are being made for a 10-stamp mill, to be erected this fall. The Jupiter has cut a new vein, carrying native gold in cross-cutting at the 300-ft. level. The shaft on the Krist property, adjoining the McEneaney, has been put down 50 ft., and a contract for sinking it another 50 ft. has been let. A promising vein found on the surface has been uncovered for some distance, and a plant has been ordered.

The principal feature of Cobalt mining matters lately has been the continued slump in La Rose, which is now selling around \$2.75. All sorts of rumors as to the cause of this decline are afloat. It is alleged that the mine has been botomed, one fact giving color to this supposition being that an open-cut is being made, and the famous 'silver sidewalk' of the Lawson property removed. This vein, showing about 2 ft. of very rich ore, has been well stoped out underground. The Nipissing is making heavy shipments of bullion. The output of bullion from the Cobalt district for the year up to September 7 was in all \$1,970,651, of which \$1,499,799 came from the Nipissing. The Beaver, which recently took over the Donaldson property in the Elk Lake district, is planning for development operations on an extensive scale, and has ordered a large plant. The Waldman is being unwatered for an examination by W. L. Malcolmson of London on behalf of prospective British purchasers. At the Peoples mine, formerly the Black Consolidated, good indications have been found on the 200-ft. level, where one vein runs over 18 inches in width and carries good milling ore. The King Edward mill is being used by the City of Cobalt mine. The reopening of the former mine is being arranged. Development is being actively carried on at the Jajola property in northern Cobalt, where the shaft is 200 ft. deep. The royalties payable by the Cobalt townsite have been reduced from 25% of the gross earnings to 15%

of the net earnings. Good discoveries have been made at the Miller Lake-O'Brien in the Montreal river district, where a winze sunk 45 ft. below the 250-ft. level shows good ore all the way. This year the mine has shipped two carloads of ore, no grade lower than 4000-oz. ore being sent out, owing to the cost of transportation. A Toronto syndicate, represented by A. P. Seymour, former manager of the Cobalt Lake, has bought claims at Hubert lake in the Elk Lake district from C. W. Haentschel of Haileybury and Samuel Tongue of Mattawa, for \$1,000,000.

It is denied that the Bewick-Moreing syndicate has withdrawn from Canada. They have abandoned Poreupine, but are stated to be organizing a system of investigation for new Canadian mining districts. The offices are to be removed from Montreal to Toronto, the latter being nearer to the mining districts in which they are likely to operate.

### JOPLIN, MISSOURI

RECORD SHIPMENT OF ZINC AND LEAD ORES.—METAL MARKETS AGAIN AT HIGH FIGURE.—EXTENSIVE PROSPECTING WITH CHURN-DRILLS.—NOTES OF THE MINES.

The month of September is featured by unusually heavy shipments of zinc and lead ores, the record for the week ended Saturday, September 7, having been the greatest in the history of the Missouri-Kansas-Oklahoma district. For the week in question, the aggregate valuation of ores was \$469,972. The nearest weekly valuation was reported two years ago, when the aggregate reached \$440,000. The average weekly valuation is about \$300,000 in years of exceptional prosperity, and considerably below this figure at other times. High prices have so stimulated production that weekly shipments of zinc ore are now running close to 6000 tons, including calamine. The record week mentioned saw a shipment of 7650 tons, the accumulation from the previous week having been almost completely absorbed in the big shipment. Producers have been troubled to some extent by a shortage of cars, but this condition is being remedied to some extent. Prices for zincblende are now ranging from \$55 to \$60 per ton, basis of 60% metallic zinc, while choice lots bring \$63. Spelter at East St. Louis is at its highest point in a quarter of a century, being quoted at \$7.30, while New York metal is quoted at \$7.50. Pig lead, likewise, is strong, St. Louis quotations having risen to \$5.025, an increase of more than 60 points in the past few weeks, while New York pig lead is quoted at \$5.15. The system of buying lead ore in this district has undergone a decided change, the ore now being purchased on an assay basis instead of on flat bids as heretofore. An 80% metallic content is fixed as a basis. The price of this ranges from \$60 to \$62. For ores carrying higher than this, \$1 premium for each unit of lead is added. A like deduction is made from low-grade ore.

Prospecting with churn-drills is being carried on everywhere in the district, and in many places where no mining has heretofore been done. In the latter class are the operations of the Granby Mining & Smelting Co., on a large tract between the towns of Duenweg and Granby, Missouri. Lead ore is indicated in the 'clippings.' Old ground that has been reopened includes the once famous Bankers tract in the southeast part of Joplin. Leases long idle have again been prospected, and operations are being carried on beneath the old workings. A deep run of blende has been found by A. McDonald and J. White in drilling a hole on the Big Six lease at Duenweg. The ore began at 205 ft. and continued to 214 ft. On the Glenn land, in the southern part of Carthage, W. B. Shackelford, manager for the S. Y. Ramage interests, has sunk several holes into thin sheet-ore. In the Neck City field, Hill, Jones, and Van Hoose have found shallow pocket bodies of ore at 87 to 122 ft. in one hole, and at 112 to 200 ft. in a deeper hole.

Boston people have purchased for \$10,000 the old Hoo Hoo mine, west of Joplin, operated by Pearl brothers. Two ore-levels are found, one at 80 to 130 ft., and another, sheet ore, at 180 ft. The upper ground only is

to be worked at this time. A new concentrating plant is to be constructed soon.

One of the most complete mills in the West Joplin district, a plant run by electricity and equipped with sand-jigs, tables, and settling-tanks, is that built by the Underwriters Land Co., operators of the Yellow Dog properties north of Webb City. West of this mine the W. O. Cragg Mining Co., already operating a 150-ton concentrating plant, will begin the erection of a second plant of 250 tons capacity. At a depth of 200 ft. ore has been blocked out in drill-holes and prospect drifts. Individual motor drives for all parts of the machinery are employed at the new plant of the What Cheer Mining Co. No line shafts are in evidence in this plant, and in this respect the mill is decidedly different from any other of the Joplin district. Each set of jigs, pump, hoist, and other pieces of machinery is operated by a separate motor. The experiment is being watched with interest.

The Pratt-Durkee Coal Co., of Skidmore, Kansas, has purchased for \$15,000 the Glendenning mine, west of Joplin. The lease is well opened, disseminated orebodies having been blocked out, and a small concentrating plant is on the property. The new operators have re-named the mine the Jediah.

### RHODESIA

OUTPUT FOR JUNE.—ENCOURAGING DEVELOPMENTS AT SHAMVA.—THE TANGANYIKA TANGLE.

The mineral output of Southern Rhodesia for the month of June was of a value of £248,909, as compared with £246,543 in May. The different items of production were as follows:

	May.	June.
Gold .....	£234,407	£226,867
Silver .....	1,696	1,826
Lead .....	729	5,928
Chrome iron .....	4,375	13,750
Coal .....	5,336	5,538
Totals .....	£246,543	£248,909

While the gold yield was low for the month, the increased output of lead and chrome iron were compensated

MILL AT GIANT MINE, RHODESIA.

for it and the total output of minerals for June was higher by £2366 than that for the preceding month. The gold industry has been much troubled by the prevailing drought, and it was anticipated that the output would show an even larger decline. The general outlook is hopeful and the prospects of an increased gold output are good. The Shamva should be crushing within a year, and before then the Cam & Motor mines should be producing. These are two of the most important properties in Southern Rhodesia, and their advent as producers should substantially augment returns. The Hartley and Bulawayo districts continue to do well as a whole, but it is disappointing to hear unsatisfactory news from the Giant Mines at Gadzema and the Eldorado in the Loma-

gundi district, two mines which long have been the mainstays of the Rhodesian gold industry. At the former property the vein has been 'lost', and although the prospect of its rediscovery by boring is stated to be good, the position is not nearly so satisfactory today as it was a little while ago. At the Eldorado the ore-shoot has greatly decreased in size, and despite reassuring reports from the consulting engineers, it is patent that the mine is in a none too encouraging position.

The Shamva appears to be developing in a manner which must be satisfactory to shareholders. There are now about 2,200,000 tons of 5 dwt. ore blocked out. The new Nissen stamp crushing equipment, which is due to start in about a year, will have a capacity of 40,000 to 50,000 tons per month, the largest reduction plant in Rhodesia. Even at the maximum tonnage, the ore reserve in the Shamva at the present time is nearly four years ahead of the mill, and since development is to be pushed during the construction period, it is probable that the Shamva will commence milling with a five-years supply or more. This state of affairs is quite exceptional in Southern Rhodesia. The speed with which the equipment is erected will, very naturally, be dependent in no small degree on the progress of construction work on the Salisbury-Abercorn railway and the facilities presented for transporting material. It looks, however, as if the Shamva company will, without much difficulty, have everything ready for milling about the middle of next year. Whether a sufficient supply of unskilled laborers will be forthcoming by that time to operate this large equipment remains to be seen.

It is understood that Alan Gibb, chief resident engineer in the Katanga to the Tanganyika Concessions, is not returning to Africa, nor, so it is reported, is the chief metallurgist. It is an open secret that smelting operations at Lubumbashi, near the Star of the Congo mine, have been unsatisfactory, and it is generally known that there has been a great deal of ill feeling, argument, and controversy between directors and high officials of the copper company. What the upshot of it all will be is difficult to say, but it is understood that fresh technical blood is to be imported and the scheme of treatment will be materially altered.

Meanwhile the Wankie Colliery Co., in northern Matabeleland, is making great preparations for supplying these remote copper mines with large quantities of coke. The operating cost at Katanga when European coke was employed was well-nigh ruinous. Accordingly, some agreement has been made between the copper company and the colliery, and the Wankie people are erecting a large coke-plant. What system of treatment is to be adopted in the future is not disclosed. Perhaps this is because no one knows how the Tanganyika tangle is going to be straightened out.

### JOHANNESBURG, TRANSVAAL

GOOD ORE IN MODDERFONTEIN DEEP.—REEF CHARACTERISTICS.—GOOD LUCK FOR THE GOERZ GROUP.

The principal mining topic during the past week has been the discovery of unusually rich ore in the Main Reef in the No. 1 shaft of the Modderfontein Deep at a depth of 2990 ft. from the surface and dipping 11° south. This vicinity is regarded as the most interesting area in the Far East Rand, because it is the only portion of the Rand where shaft-sinking and development operations are being extensively carried on, and above all, because it is an area where there have occurred almost as many striking failures as successes. Above the Modderfontein Deep (the scene of the recent discovery) occurs the extensive New Modderfontein mine, a fairly successful undertaking as Rand gold-mining goes. But the fact that above the rich discovery on the Modderfontein Deep the same vein in the New Modderfontein property is of lower average grade than farther to the east in the same property is only another instance of the long-recognized local varia-

tions in grade which the Main Reef on the Rand is likely to show. Below the Modderfontein Deep lies the extensive property known as the Government Areas, where the Main Reef was recently cut in the Northwest shaft, the nearest shaft to that of the Modderfontein Deep, at a depth of 2395 ft. from the surface. But in this instance its width only averaged 31 in., assaying over the four sides of the shaft at 7.15 dwt. per ton. But this failed to arouse anything like the same enthusiasm in mining circles as the Modderfontein Deep. The following is the official account of the discovery on the Modderfontein Deep: "The Reef series consists of a hanging-wall leader assaying 24.88 dwt. over 27.9 in., including partings, followed by 31 in. of waste. The middle reef assays 23.78 dwt. over 6 in. and is separated by 22.6 in. of waste from the foot-wall leader, the latter being 39 in. wide, including partings, and assaying 7.26 dwt. per ton. The average of the whole body, including waste, is 126.5 in. wide, assaying 8.84 dwt. per ton."

It may be interesting to reproduce the results of the different bore-holes on this property, put down some time before shaft-sinking operations commenced. No. 1 bore-hole struck the Main Reef series at a depth of 2967 ft., the section and assay values being as follows: Vein 1¼ in., assay value 6 dwt., quartzite 16½ in., vein 1½ in., assay value 64 dwt., quartzite 66½ in. overlying another vein 2½ in. thick assaying 5 dwt., quartzite 9 in., vein 38¼ in. assaying 8 dwt., quartzite 3 in., vein 14¼ in. assaying 4 dwt., quartzite 6 in., vein 3½ in. assaying 2 dwt., and vein 1½ in. assaying 6 dwt. resting on foot-wall slate at a depth of 3099 ft. No. 2 bore-hole missed the vein altogether, but struck the foot-wall at a depth of 2520 ft. No. 3 bore-hole struck the Main Reef series at a depth of 2903 ft., assaying 15½ dwt. over a width of 12 in. These different sections show how variable are the different conglomerate beds comprising the Main Reef series both in value and thickness, even on the same property.

The Goerz group of mines, controlling the Modderfontein Deep levels, are to be highly congratulated upon first striking the Main Reef series at what may possibly be the best developed section and carrying the richest ore of any other spot probably on the property. It is also to be hoped that these published results, obtained from over 70 samples, may not prove so illusory as was the case with those first issued under similar conditions at Geduld. It will be remembered test sampling and assay results there failed to bear any resemblance to those first published as contained within the narrow limits of the shaft when it first cut the vein—a mystery to the investing public which up to even today has not been cleared up. This satisfactory Modderfontein Deep result will be all the more welcome because it has been obtained by a group that in the immediate past has shown considerable if not well considered enterprise in launching out and spending considerable sums in acquiring and prospecting properties on the Western Rand. These have developed in anything but a satisfactory manner, and today they hold large areas of somewhat doubtful value.

Owing to a variety of causes, artificial and otherwise, ill luck and decreased mining profits have for some time past dogged the footsteps of this group—more so than of any group on the Rand. It is therefore pleasing to see that there is a prospect of better times to some extent for the shareholders in this particular group. The satisfactory results obtained in the Modderfontein Deep levels will confirm the good opinion always held of the value of the New Modderfontein property, and likewise the better indications to the east noted in development work of the adjoining Van Ryn Deep. They ought also to encourage the shareholders of the Government Areas, where encouragement is much more needed than in the case of Brakpan, where some benefit may also be expected to be reaped. The directors of the Central Mining & Investment Corporation have announced an interim dividend of 6s. per share. It is the intention to pay dividends at the rate of 5% per year, and distribute the excess as a bonus.

## General Mining News

### ALASKA

#### CORDOVA

Owing to a heavy gale blowing on Controller bay, the Alaska Railway Commission will not land at Katalla on the north-bound trip, but will go direct to Seward. From there they go to Knik and the Matanuska coalfield, returning by way of Chitina and the Copper River railroad; after which they will visit Katalla and the Bering coalfield. Advices state that the steamer *Victoria* has arrived at Seattle, bringing \$500,000 gold and 60 tons of furs from Seward Peninsula and Iditarod.

#### FAIRBANKS

A 60-hour run on Windy bench, with eight men shoveling into the sluice-boxes, resulted in a clean-up worth \$4000. A 2-stamp Nissen mill is being erected by Hudson brothers on their quartz claim, between Ready Bullion and Moore creeks, above Ester City. The stamp-mill of McIlroy, and party, on Chatham creek, should soon be at work. It was found necessary to make the mortar blocks 36 ft. deep to get proper foundation. A good discovery has been made by Crites and Feldman, on Moose creek, a tributary of Fairbanks creek, in uncovering an extension of veins found some time ago. Pan tests show it to be high-grade. Gravel averaging \$2 to \$2.50 per square foot of bedrock has been found on No. 2 below left limit bench, on Fairbanks creek. This is the third discovery since the beginning of this year on this creek. Reports from Iditarod state that men are going to the new finds at the George river. One dump returns as high as \$1.38 from seven pans, and \$1.20 per pan from the bottom of a hole. The ground is shallow and offers good working conditions. Its extent is not yet known. Material for the Flat creek dredge is at Iditarod, but the Guggenheim people may not get it finished this season. Many are leaving, and under 200 will be in camp at the beginning of October.

### ARIZONA

#### GILA COUNTY

At the Inspiration Consolidated mines, about 500 men are employed, and McArthur Bros. are employing 175 men on railroad construction. The extension of the main line of the Arizona Eastern, from Miami up Keystone and Live Oak gulches, to the Inspiration adit, and the Live Oak mine, was started this week. In August, 4900 ft. of development was done, and the rate is increasing. Churn-drill hole No. 3, at the South Live Oak is 630 ft. deep, and is reported to have cut chalcocite-bearing schist at 610 ft., though not of profitable grade. Results are considered encouraging. At the Southwestern Miami, churn-drill holes 6, 7, and 8 are respectively 935, 989, and 880 ft. deep, in schist. The enlargement of hole No. 8 to 6¼-in. size by under-reaming has been finished, and drilling will be resumed. Good ore was reported as found in this hole at a depth of 820 ft. J. A. Fleming has taken a lease on the old Irene silver mine in Irene gulch, about two miles north of Globe. The group consists of nine claims, and has silver-bearing veins in quartzite, diabase, and limestone. The mine was a producer of high-grade silver ore in the early eighties. The Iron Cap Copper Co. has just shipped a car of oxidized copper ore to the Old Dominion smelter. It runs high in iron, and is estimated to assay about 8% copper. Another car is now being loaded. The ore is coming from the 4-ft. shoot recently opened on the 650-ft. level. Driving continues east on the ore at this level, and a drift has just been started east on the 800-ft. level, to cut the same shoot. There are 12 men employed. F. A. Woodward is manager, and H. W. Woodward, superintendent. Globe, September 12.

#### PINAL COUNTY

In a report to the shareholders of the Calumet & Copper Creek Mining Co., M. A. Tew, vice-president, states that the power-plant, transmission lines, and machinery on the

property are working well; and shareholders have reason to be satisfied with the present showing. The mill was started on July 2, and after several adjustments, is working splendidly. Concentrate from the Old Reliable mine averages 20% copper, worth about \$60 per ton. Concentrate from the American Eagle is worth \$35 to \$40 per ton. Grading for a narrow-gauge railroad is finished between the Old Reliable and the mill, which should soon produce 25 to 30 tons of concentrate per day. At present, concentrate is hauled by teams to Winkelman, thence by rail to the El Paso smelter. An Isbell vanner is to be tried in the mill, this make having done good work at other large copper concentrators.

#### SANTA CRUZ COUNTY

(Special Correspondence.)—One 50-ton car of copper ore per day is being shipped to El Paso smelter, according to W. S. Sultan, superintendent of N. L. Amster's R. R. R. mine near Patagonia, but the grade of the ore is not stated. A considerable tonnage of low-grade ore is accumulating on the dump. The vein has been opened by drifts at the adit-level for a distance of about 500 ft. and driving north continues. A width of 40 ft. is reported at two points at which it has been cross-cut. A winze is being sunk on the vein, has reached 90 ft. below the adit-level, and a

MORENCI, ARIZONA.

drift has been started at 60 ft. in depth. The sinking of the 375-ft. two-compartment shaft will be continued to the adit, a distance of about 600 feet. Six machine-drills and 70 men are employed. The Copper Queen company, after an examination, has taken over the Bradford mine belonging to the Ferry estate. The property is 3 miles west of the R. R. R. mine, and a mile west of the Amster spur at Bloxton. About one car of copper carbonate ore per week is being shipped. The Chief Group of claims, owned by B. Curtis, W. Powers, and others, has been bonded by El Tigre people, and a 500-ft. cross-cut has been started. The claims lie 1½ miles northeast of the R. R. R. mine, and adjoin the famous World's Fair mine, owned by F. Powers. The ore carries copper, lead, and zinc. The Hosey mine, nine miles due west of Patagonia, and owned by J. McDonald and others, has been bonded to Mr. Posey, former owner of the Gold Road mine, and Mr. Frazier. Three cars of copper-silver ore per month are being shipped. The Morning Glory mine, owned by C. B. Wilson, is shipping two cars of copper ore per week to the Pioneer smelter.

### CALIFORNIA

#### AMADOR COUNTY

(Special Correspondence.)—The shaft of the Keystone, near Amador City, has reached a depth of 1800 ft., or about 400 ft. below the old workings. Sinking will probably continue to the 2400-ft. level. It is estimated over six months will be required to complete the shaft. In the upper levels considerable milling ore is blocked out, and indications are considered favorable for intersection of the veins at further depth. C. R. Downs is manager. The South Eureka and Central Eureka companies have recently purchased land suitable for dumping places for mill tailing. A large dam will be erected, and the tailing pre-

vented from flowing upon and damaging agricultural lands. The material from the South Eureka will flow to the ground through a ditch, while a trestle and pipe will be part of the outlet for the Central. Both mills will discharge tailing behind the same impounding dam. Developments on the 2700 and 2800-ft. levels of the Central Eureka are reported to be satisfactory. The new vein recently cut on the 2800-ft. level shows well. It is understood that the full complement of 40 stamps may be in operation soon, if enough ore is available. Unwatering the lowest workings of the Plymouth Consolidated is going ahead and unless the old workings are badly caved, the management intends to start development within a few months. So far the shaft is said to be in a fairly good state of preservation.

Jackson, September 16.

#### MERCED COUNTY

The Original company, in the Merced river canyon, cleaned up bullion worth \$5100 from 16 days' work, 335 tons of ore being crushed. Only half of the mill worked for nine days, but it is hoped to keep the 10 stamps running in future. The 200-ft. level is in 90 ft., and will go 200 ft. further. Twenty-five men are employed.

#### NEVADA COUNTY

The new hoist at the Gold Point mine has been erected and the head-frame is now being constructed. This mine is between the Brunswick and Maryland properties. The shaft is down 248 ft., and driving from this point is in progress, cutting good ore. It is intended to sink to 1000-ft. depth. The new electric line to the Montana mine, in Willow valley, is completed, and electric power is now used for driving the compressor. It will also be used for hoisting and pumping. Prospects at the mine are satisfactory. H. Kitts and others have bonded a portion of the bed of Deer creek, near Kendrick, and will erect a dredge, which will be driven by electric power.

#### SHASTA COUNTY

(Special Correspondence.)—The Noble Electric Steel Co. has resumed iron production at its Heroult smelter. The single furnace is yielding 15 tons per day. Framework for a second unit is being erected. The company intends to add new furnaces from time to time. It is stated that success has crowned the efforts to produce gray iron. The by-products plant is producing charcoal, tar, and various chemical products of value. Repair work at the Afterthought copper mines is being completed, and active development is expected to commence within a few weeks. Experiments with the new process continue, and its success is understood to be assured. Preliminary work on the route of the railroad from Bella Vista to Ingot is nearly finished and the company intends to start soon with construction work. With the prospect of early working, the Ingot smelter, gold mining in the district is stimulated. The Moonlight owners have ordered a 5-stamp mill, and machinery is arriving. The ore carries gold with pyrite. Promising discoveries have been recently reported by prospectors in different portions of the field. It is again rumored that the Bully Hill Copper Co. is contemplating resuming work at Delamar. The management has been experimenting for several months with a process designed to obviate the smelter-fume question.

Redding, September 16.

#### SIERRA COUNTY

The adit driven on the lode at the Fruitvale mine, on the Middle Yuba river slope of Lafayette ridge, is in 700 ft., and a cross-cut shows it to be nearly 40 ft. wide, carrying gold. The lode was 20 ft. wide at the mouth of the adit, and only got narrower in a few places. Machine-drills are used on two shifts. The quartz in the lode carries a fair percentage of pyrite. A bond has been obtained on the Eagle and Arizona claims, and the 800-ft. adit, driven some years ago, has been cleaned out and retimbered. E. Miller and C. Edwards are driving an adit to cut the vein on their claims near the Seventy-Six, on Kanaka creek.

While doing assessment work on the Alhambra mine, near Poker Flat, a new ore-shoot was discovered which pans well in gold. This mine has a series of quartz veins enclosed in a large dike of mariposite. Pay-gravel has been found in claims on the Clarks canyon side of Rattlesnake last week, in a 35-ft. raise from the face of the 350-ft. adit. It is a blue quartz gravel, and \$7 in coarse gold was recovered from a few loads washed.

### COLORADO

#### GILPIN COUNTY

An orebody 36 to 48 in. wide has been opened on the 100-ft. level of the Federal mine, in the Russell district. A small vein assays up to \$180 per ton. The ore carries zinc and copper, and about 20 tons has been broken out. The main shaft at the Ralls mine is 675 ft. deep, and the vein is 30 to 36 in. wide, showing good smelting ore. A new ore-shoot has been discovered in the Alps mine, at a depth of 80 ft., and assays return from \$41 to \$237 per ton in gold, silver, and copper.

#### LAKE COUNTY (LEADVILLE)

At the Boston group of claims, at the head of Mayflower gulch, a lode 10 ft. wide has been cut, but its full width has not yet been proved. It assays from 70 to 75% of lead, with good gold and silver content. The lode has been traced on the surface for about 3000 ft. During August the Eureka company sent out 26 cars of ore from the new find at Columbine shaft. The returns were from 26 to 60 oz. of silver per ton, and a fair percentage of lead.

#### SAN JUAN COUNTY

The State Commissioner of Mines, T. R. Henenan, had the following to say about the southwestern district to the *Denver Post*: "The region about Silverton is in a very prosperous condition and the people are sanguine about the future. The Gold King mine and mill are running full time, the Silver Lake and the Iowa Tiger mines and reduction works are very active. The Sunnyside is steadily producing, and earning large returns through the successful operation of its electrostatic zinc plant. The Congress mine at Red Mountain is employing about forty men in the production of gold, silver, and copper. The manager of the Bagley adit, at Animas Forks, has his big mill nearly completed. The Champion mine, on Sultan mountain, is working a full force of men. Several other properties are in operation and are turning out a good deal of ore."

#### TELLER COUNTY (CRIPPLE CREEK)

A pump is to be installed in the Eclipse shaft of the El Oro in Eclipse gulch, and 300 ft. of water removed as soon as possible. A cross-cut will be started in the Comanche Plume adit to open the main orebody outcropping in the upper Eclipse adit. Good ore has been cut in the Mollie Katheleen; shipping is to be resumed at the Kalamazoo claim; and the Chickenhawk has three machines at work on the 1000-ft. level.

During the year ended August 31 the Jerry Johnston shipped 1315 tons of ore having a gross value of \$182,059 and net value of \$104,442. Dividends amounting to \$24,978 were paid. The main shaft is 975 ft. deep, but little work has been done below 650 ft. It is proposed to erect a mill. Water in the Gold Coin shaft is 89 ft. below No. 10 level, and is receding at the rate of one inch per day. Installing the new pumps at the 1600-ft. level of the Golden Cycle is well advanced. The Trilby mill is to be dismantled shortly.

### IDAHO

#### IDAHO COUNTY

There has been general activity in mining in the Elk City district of late, and the outlook is bright. Mills at the Mineral Zone, Last Chance, and South Fork are working, while the crusher, Huntington mill, and Pelton wheel at the Mascot are all in place and should be soon running. At the Penn-Dixie, No. 1 adit is now in 800 ft. At present a shaft is being sunk on the Keystone claim,

and a small vein is yielding some rich ore for the mill. The latter has been overhauled and a cyanide plant built for treatment of part of the tailing.

#### SHOSHONE COUNTY

The property of the Clearwater Copper Mining Co., situated at the headwaters of the north fork of the Clearwater river, promises to be a big mine. In the lower adit of this property, an ore-shoot 1400 ft. long has been opened, it is reported, and cross-cutting has proved it to reach 30 ft. in width, carrying copper, gold, silver, and lead. The mine is well equipped, and there is ample water-power. This district is rather remote, being 14 miles from the regular wagon-road. The United Lead company, near Osburn, is reported to have cut good ore in a drift driven on a lode in the lower adit. The drift is about 4000 ft. long. The Snowstorm mill, at Larson, has been shut down for some time for repairs. A heavy flow of water has been met with in the Silver Cable, east of Mullan, in the new adit, which is expected to cut the lode 100 ft. below the discovery. The consolidation of the Surprise and Highland Chief companies was practically completed last week.

### MICHIGAN

#### HOUGHTON COUNTY

The J. A. Roebling Sons company has purchased the plant and 304 acres of land belonging to the Dollar Boy Land & Improvement Co., and the Tamarack & Osceola

MINING AND METALLURGICAL BUILDING,  
MICHIGAN COLLEGE OF MINES.

Manufacturing Co. The present wire mill will be enlarged, a steel-wire mill added, and other finished copper products will be produced for the Western trade demands of the Roebling company.

### MISSOURI

#### NEWTON COUNTY

The smelting plant of the Granby company, at Granby, was destroyed by fire on September 10, the damage being assessed at \$100,000. Fire is supposed to have started from a spark from the furnaces. The milling plant and laboratory were saved. About two years ago the mill was burned down. The lead smelter had not been at work long, and its loss will take from the Joplin district an active buyer of lead ores, until it can be rebuilt.

### NEVADA

#### CHURCHILL COUNTY

The debt of the Nevada Hills company is now \$275,000. The mine makes 30,000 gal. of water per day, of which 17,000 gal. is needed for the mill, which is now treating 125 tons of ore per day.

#### ESMERALDA COUNTY

Active prospecting is to be started at the Zara company's claims, in the Hornsilver district, 35 miles southwest of Goldfield. The Southwestern company has purchased the Great Western mine and will begin work on a large scale. The Hornsilver company has opened some good ore by cross-cutting from its 300-ft. level. The

shaft is down to 460-ft. depth, and at 500 ft. cross-cutting will begin. This district is isolated and lacks good transportation and milling facilities.

A number of Goldfield people have filed placer locations to the east side of Silver Peak, about 20 miles west of Goldfield, on a salt marsh or dry lake, which is said to contain potash deposits. The district is to be thoroughly tested. The deposits were originally discovered about eight years ago by J. Shirley, of Goldfield. Several samples have yielded 10 to 15% potash salts from a depth of 6 ft. The Goldfield Midway company will sink its shaft to 500-ft. depth on its ground on the north side of Vindicator mountain. Work already done shows a lode about five feet wide. The Black Butte Leasing Co., working from the main shaft of the Diamondfield Black Butte, has cut 3 ft. of ore worth \$22 to \$30 per ton. On the second level of the Nevada Eagle high-grade ore has been opened, and the 365-ft. level is being driven to develop it further. The main shaft of the Florence Goldfield is now below 1250-ft. depth.

#### HUMBOLDT COUNTY

(Special Correspondence.)—The National Placer Co. has built a large machine on its extensive holdings in Gold gulch. The apparatus has a capacity of 1000 tons per day. Scrapers, operated by horses, are employed to excavate the material. W. T. Henley has installed a machine in the main gulch, where he has several claims. It is said the gravel is of good value. The Charleston Hill Development & Mining Co. is driving a cross-cut adit to intersect the orebody developed in the upper workings. A survey of the holdings is being made preliminary to application for patent. Regular shipments of concentrate from the National mill are being made to Winnemucca. The company is pushing work on its rich Charleston hill property. Operations have been resumed at the Gold Note mine near Kennedy. The mill is being overhauled, and it is planned to commence production shortly. Paul Klopstiek is manager. Oklahoma Mining Co. is developing milling ore in its property at Dyke. Veins of high-grade quartz are also reported. Thomas Ewing is manager. In the Yellow Dog claim a 15-in. shoot of rich ore has been uncovered at a depth of 120 ft. Some of this is said to assay about \$500 per ton. A second shoot, 2 in. wide, has also been cut. On adjoining claims, John Yates and associates are opening veins of rich quartz on the Yellow Dog vein. These properties are situated at Dyke, in the Pine Forest district. Prospectors report the discovery of a 2-ft. shoot of rich ore, eight miles from Rye Patch. Black Canyon and other sections of the Humboldt range report that considerable prospecting is under way. The Sheba, Wheeler, and other mines are being actively worked.

Winnemucca, September 6.

The offices and superintendent's house at the National Mines property were destroyed by fire last week. Books and records were saved. The old concentrate building was burned, but the mill was saved. Work will proceed as usual.

#### NYE COUNTY

At Manhattan, the Big Four company is raising from the 500 to 400-ft. level on a large orebody. The Kendall-Douglass has treated 130 tons of ore averaging \$46 per ton. From the White Caps mine 55 tons per day is sent to the Associated mill. The War Eagle mill treated 114 tons valued at \$28 per ton, for lessees at the Litigation Hill Merger, formerly Bath lease. Twelve feet of ore has been opened by lessees at the Indian Camp. The Manhattan Milling & Ore Co. is to erect a new cyanide plant.

The new pumping plant at the Manhattan Big Four, with a capacity of 300,000 gal. per day, is now at work. Plans for the new mill have been approved and construction will be started soon. An effort is being made to finance the old Manhattan Mining Co., one of the first companies at Manhattan. During August the Tonopah Mining Co. treated 14,429 tons of ore yielding bullion valued at \$227,100, including the value of 62 tons of con-

centrate, and the net profit was \$129,368. Ore production from the district for the past week totaled 10,205 tons, worth \$255,125. The Tonopah-Belmont sent out bullion weighing 20,466 oz. on September 11. The mill is treating an average of 500 tons of ore per day. At the Midway a new shaft is being sunk. On the 600-ft. level of the West End the cross-cut has gone through 25 ft. of ore, with no hanging wall in sight, averaging \$25 to \$30 per ton. The mill will be treating 135 tons per day in a few days. The North Star has cut a vein of good-grade ore on its 1250-ft. level. On last payday at Tonopah the sum of \$250,000 was distributed among the men.

#### STOREY COUNTY

At a special meeting of the Comstock Pumping Association, held in San Francisco, the use of Ward shaft was offered to the mines of the Gold Hill section, the offer remaining open till September 20. If not accepted, machinery will be lifted from the 2150-ft. station, and water will rise to the Sutro tunnel level. During the week ended September 14, reports on the Comstock mines contained the following: The water at Ward shaft has been kept at 50 ft. below the 2150-ft. station, the vertical centrifugal pump at the C. & C. shaft worked well, and various repairs were made in the shaft. The Mexican mill crushed 477 tons of ore averaging \$24.95 per ton, with an extraction of 95%. On the 2500-ft. level in the north drift, out 250 ft., a winze was sunk 14 ft. on the vein, showing on the north about 42 in. of quartz, worth \$3.15 to \$9.33 per ton; and on the south 18 in. of low-grade ore. Twenty-one tons of \$17.33 ore was taken out of this opening. At the Ophir cyanide plant the tube-mill, Dorr thickener, solution tanks, and foundation for Butters filter are about complete. The usual work was carried on at the Consolidated Virginia, Union Consolidated, Sierra Nevada, and other mines.

#### WHITE PINE COUNTY

At the Boston Ely the shaft is 1260 ft. deep, and from 15,000 to 20,000 gal. of water has to be pumped daily. A new boiler and compressor are being erected as fast as possible.

The Nevada Consolidated company is contemplating resumption of work at the Ruth and Star Pointer properties. Mining here will have to be done by the caving system. Over 8,000,000 tons of ore averaging 2½% of copper is opened. The Ruth shaft, used mainly for ventilation, is down 610 ft., and the Star Pointer shaft 495 ft. deep. The two mines are connected by a drift 2700 ft. long.

### NEW MEXICO

#### GRANT COUNTY

At the Pacific No. 2 mine of the Savanna Copper Co. lessees are sinking a shaft to 100-ft. depth. The old adit has been cleaned out and stoping is in progress, and one car of ore per week is sent to El Paso smelter. Foundations for the electric plant at the Emma mine, at Fierro, are nearly finished. It is thought that the Phelps-Dodge company will work its mine at Leopold when a railway is constructed to that place. The Twin Peaks company is erecting a 100-ton mill and cyanide plant.

#### SOCORRO COUNTY

(Special Correspondence.)—The Ernestine company treated 1354 tons of ore during the two weeks ended September 12, and produced 10,360 oz. of bullion in 10 days, besides 5 tons of concentrate. Thirty stamps should be regularly at work from now on. At the Socorro the lower levels are in good ore. The Deadwood mill crushed 1700 tons in August, and the Oaks Company sent to the mills 461 tons averaging \$17 per ton.

Mogollon, September 13.

### UTAH

#### JUAB COUNTY

As far as can be learned, there is no wage trouble brewing in the Tintic district, the rumors to that effect

being caused by the miners' action at Bingham. Tintic producers of zinc ore have been notified that shipments of ore under the reduced freight rate began on September 16.

A meeting of the mine employees of the Tintic district has been held, and they felt that a raise in wages is within reason, considering the cost of living, that wages have remained at one scale for some years, and the present profitable returns from mining generally. Miners at present receive \$3; machine and timbermen, \$3.25; and shovelers, \$2.75 per day. The new electrically-driven compressor at the Swansea Consolidated, at Silver City, is working, and should reduce costs somewhat. The Chief Consolidated sent out 50 carloads of ore during the past two weeks. The Yankee Consolidated received \$4357 for ore shipped in August. The Gold Chain company has paid a second quarterly dividend, of 2c. per share, amounting to \$20,000.

#### SALT LAKE COUNTY

At a meeting of the Bingham branch of the Western Federation of Miners, a ballot on the wage question was taken, and showed 9 to 1 in favor of a strike if the mining companies do not grant an increase of 50c. per

BINGHAM CANYON OPEN-CUT MINING.

day for practically all classes of labor. Should a strike be declared, about 3000 men would be involved. The companies have already agreed to a 25c. increase.

As a result of the above-mentioned meeting, a general strike was started at 7 o'clock on Wednesday morning, and by 10 o'clock all the mines were idle. C. H. Moyer, president of the Federation of Miners, advised against an immediate strike, but was overruled by a unanimous vote.

#### SUMMIT COUNTY

At the annual meeting of the New York Bonanza it was stated that 3767 ft. of development had been done at a cost of \$18,779, or about \$5 per foot. Shipments were made from the 400 and 500-ft. levels, but the ore was too poor to pay. Between these levels there are several thousand tons of ore averaging 12 oz. of silver and 2% lead. A raise above the 200-ft. level shows fair ore. Receipts totaled \$36,736, and there was a loss of \$3334 on the year's work. The mill at the Ontario is now complete and should soon be at work. Notice has been served on all 'jiggers' along 'Poison creek' that they must cease making concentrate from the tailing from the mills of the Daly West, Daly-Judge, and King. It is expected that a lawsuit will result. Shipments for the week totaled 1310 tons from four mines.

### AUSTRALIA

For the first seven months of the current year the mints at Melbourne, Perth, and Sydney received for coinage gold valued at \$7,725,000, \$14,485,000, and \$7,380,000, respectively.

#### QUEENSLAND

Three new mining bills are now before the Parliament

of this state, namely, 'Drainage of Mines,' 'Mines Regulation Act Amendment,' and 'Mining for Coal and Mineral Oil.' For the first six months of 1912 the production of minerals, except coal and gems, in Queensland, was valued at \$7,920,000. The annual report of the Chillagoe Copper Co. is rather discouraging. This company owns mines, a railway, sampling plant, Huntington-Heberlein and Dwight-Lloyd machines, blast-furnaces, and converters. The metallurgical problems require a high degree of technical skill, and the price of coke is high. The year's revenue was \$1,715,000, and there was a deficit of \$16,000.

#### TASMANIA

During its past financial term of six months, the well known Mt. Bischoff tin mine produced 404 tons of tin from 113,178 tons of ore stamped, at a cost of \$1.10 per ton, not including smelting. Its revenue was \$400,000; gross profit, \$214,000; dividends paid, \$180,000; making total to date \$940 per \$24 share; and \$505,000 carried forward to current account.

#### CANADA

##### COBALT

There has been a rush to Gauthier township, in the Larder Lake district, where it is reported large veins show free gold. One claim has been sold for \$10,000. For stealing silver ore from the Millerette and O'Brien mines, one man received two years, and another three months in jail, while the charge against a third man was dismissed. La Rose company has started to mine the famous Lawson vein 'silver sidewalk,' which was always shown to visitors to the camp.

##### PORCUPINE

The Schumacher mine, at Pearl lake, has been flooded. The accident happened on the 100-ft. level in cross-cutting north for the McIntyre veins, and all workings filled with sand and water at this shaft. Another one will have to be sunk; and deeper than 100 ft. before cross-cutting toward or around Pearl lake can be safely done. The lode in the Hughes claim has been cut on the 150-ft. level and is richer than on the upper levels. In addition to the value of the quartz, the schist was rich in gold. Work at the Three Nations Lake and Dome Lake properties is promising. Foundations have been started for the powerhouse of the Porcupine Lake company.

##### YUKON

During August the Yukon Gold Co. dredged 982,900 cu. yd. of gravel, yielding gold worth \$641,700, equal to 65¢ per yard. For the season to date 3,464,000 cu. yd. have been dealt with, yielding \$2,402,400.

August 24 was the sixteenth anniversary of the discovery of gold on Bonanza by Robert Henderson; and the Dawson *Weekly News* devotes some space to the subject. It says in part: "It was the find on the creek near Dawson which sent tens of thousands hurrying through the Northland, the find which made Klondike, Nome, Fairbanks, Koyukuk, Iditarod, and numerous other districts. These placer districts led to the opening of copper mines on the Copper river, Whitehorse, and at the head of the White river. The Bonanza find brought on the discovery and development of Alaska's rich inland coal-lands. The prospector remains a live factor in this territory. Yukon has every reason to celebrate the discovery which brought about the awakening of the northern empire." The total production of gold from the Yukon Territory, and small neighboring districts, amounts to \$169,000,000, from officially recorded returns. At Oglivie bridge, two miles from Dawson, two dredges, which are duplicates of No. 2 dredge on the Klondike, having a daily capacity of 12,000 cu. yd., are being built.

From the Pueblo mine, seven miles from Whitehorse, the Atlas Mining Co. is shipping 400 tons of ore per day, and as soon as the railroad can handle it the tonnage will be increased to 1000 tons per day. The company employs 150 men, and its ore reserves are estimated at 17,000,000 tons.

The railroad company expects to operate the mines all winter and to be continuous shippers. A special heating plant will be put up to keep ore from freezing in the bins.

#### CHINA

At the Tayeh silver mines, at Lungkoshan, rich ore has been opened, and plans are under way for smelters to be erected nearby, while a railway is to be constructed either to the river or Wuchang. The Duisy coal mines, on Saghalien island, are said to be the best in the East, both in quality and quantity, analyses showing 71% of coke in the coal.

#### MEXICO

##### SAN LUIS POTOSI

Recently 400 flasks of quicksilver were shipped from this state to New York, this being unusual, as the output has been consumed in Mexico or shipped to Europe. The bulk of the quicksilver production comes from Moctezuma and Guadalcazar, 40 miles north and 52 miles northeast of San Luis Potosi, respectively. The former development is comparatively recent, and the mines include about 400 acres. They are situated about 5700 ft. above sea-level and have rich deposits of cinnabar, the annual production being some 1200 flasks.

##### SONORA

Mining is suffering in this state from the revolution, and many small properties have closed down for fear of being interfered with. Every effort is being made by the Southern Pacific Company to keep the railroad open between Cananea and Naco. The Cananea company has decided to erect four more Great Falls converters. The Democrata smelter resumed work after a week's shut-down for repairs.

Twenty-one bars of bullion have been stolen from the El Tigre mine; and a reward of \$5000 has been offered by the management for its recovery.

#### NEW ZEALAND

The August gold output from all mines was valued at \$340,000, against \$680,000 for the same month of 1911, the large decrease being due to strikes at the Waihi and Reef-ton mines, already noted in the *Mining and Scientific Press*.

#### PHILIPPINE ISLANDS

On July 1 the new dredge on the Guaymas river was launched, and should be at work by now. A new electrically driven dredge has been purchased from Hongkong by H. E. Nelson for work on Mariquina river. It has a capacity of 100 cu. yd. in 10 hours from 24-ft. depth. The Luzon Gold Co., which holds several properties in Tayabas, Neuva Ecija, Rizal, and on the tributaries of the Umirai and Agelo rivers, have fitted up a hydraulic plant. The Junction Mining Co. has been formed in Manila, with a capital of ₱200,000, to mine in the Suri-gas district, Mindanao.

#### RUSSIA

(Special Correspondence.)—The platinum market at Ekaterinburg is quiet, and large business can only be done at a reduced price, which sellers refuse to accept, although they have large stocks. The present price is \$37.23 per oz. for 83% metal. Offers by the *staratelli* (free laborers) are plentiful, more so than last year, and speculators who hold platinum buy more from them, paying over the above price. There has been an increase in the use of dredges for winning platinum, most of the dredges working belonging to the Platina company, operating in the Verchotur district. For osmiridium there is a constant demand, but no supply. St. Petersburg, August 25.

#### SUMATRA

The May yield of Redjang Lebong mine, near Bencoelen, was valued at \$117,500, and net profit \$60,080.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HOYT S. GALE is here.  
 E. A. AUSTIN is in Alaska.  
 L. C. TRENT is at the Palace.  
 GEORGE R. DAVIS is in the city.  
 W. P. HAMMON is in London.  
 J. E. HALL is at the St. Francis.  
 E. GYBBON SPILSBURY is in Texas.  
 FRANK SMITH is in San Francisco.  
 JOHN B. FARISH is in San Francisco.  
 A. E. BARLOW is in British Columbia.  
 E. O. McGRATH is in town from Tuolumne.  
 GEORGE L. SHELTON has returned from Katalla.  
 JOHN A. DAVIS was in the city during the week.  
 J. G. BERRYHILL was at Ludwig, Nevada, recently.  
 S. S. ARENTZ has moved his office to Salt Lake City.  
 F. W. OLDFIELD left San Francisco for Mexico last week.  
 FRANKLIN LEONARD and J. B. MENARDI are here from Nevada.  
 W. A. CARLYLE has been in Mexico on professional business.  
 V. H. HUGHES has been appointed state geologist of Missouri.  
 W. C. BOLLEY is now superintendent of the Baltic mine, Michigan.  
 T. INOUE is in Salt Lake City and will come to San Francisco.  
 J. F. CALLIBREATH was here during the week and has gone to Los Angeles.  
 A. P. ROGERS is in Panama and expects to return to New York, October 1.  
 CHARLES A. BANKS left New York, September 10, for British Columbia.  
 R. C. SPECHT is at Weaverville, California, on placer examination work.  
 CHARLES JANIN has returned from Graniteville, Nevada county, California.  
 W. H. ALDRIDGE has moved his offices from Los Angeles to 14 Wall street, New York.  
 FREDERICK HELLMANN left San Francisco, September 16, for Los Angeles and the East.  
 CECIL POCKOCK is now with the Compania Minera Santa Clara de Morochoca, Lima, Peru.  
 N. M. MUIR has left Mexico and is temporarily at 1311 Spruce street, Berkeley, California.  
 OSCAR LACHMUND has been examining placer ground in Yuba and Siskiyou counties, California.  
 W. J. ALMOND is on his way to Indiana from Rhodesia, expecting to return to San Francisco later.  
 H. FOSTER BAIN is at New Orleans, on his way to New York, where he will stay from September 30 to October 7.  
 SHIGEMA YAMANOUCHI, who has been visiting Europe and Nova Scotia, sailed for Yokohama on the *Mongolia*, September 13.  
 W. H. TANGYE has been appointed superintendent of the Calumet & Sonora, Cananea, Sonora, in place of C. W. STRAHAN, resigned.  
 GEORGE E. FARISH is on his way to Arizona to examine a copper property, expecting to return to New York at the end of this month.  
 MILLARD K. SHALER sailed from Brussels for New York on September 7 and will proceed to Lawrence, Kansas, returning to Brussels in a month or two.  
 G. McN. ROSS and GUSTAVE SCHRADER are here to attend the meeting of the local members of the American Institute of Mining Engineers, held today at 12:30 at the Sutter hotel.

## Market Reports

### LOCAL METAL PRICES

San Francisco September 19.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**METHODS IN CHEMICAL ANALYSIS.** By F. A. Goehs. 536 pp. Ill., index. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price 4.

This volume deals with methods originated or developed in the Kent chemical laboratory, of the Yale University, and is suited for advanced students. The first 73 pages cover appliances and general procedure in a condensed form. The methods are arranged in a series of chapters covering groups from the alkali metals to iron. The work is well presented, well arranged, and well printed.

**PRACTICAL FIELD GEOLOGY.** By J. H. Farrell; with a GUIDE TO SIGHT RECOGNITION OF 120 COMMON MINERALS, by A. J. Moses. Pocket size. 273 pp. Ill., index, flexible cover. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$2.50.

This is not a geology, that is, it does not treat of geological facts and history, but is a manual of methods; and a particularly good one. It is admirably adapted to help the man who has received good general training in geology but who is not familiar with practical field methods in economic work. One of the valuable features is the detail with which methods of mapping, both topographic and geologic, are given. The numerous illustrations from actual examples in the field are well chosen and well presented. Altogether the authors have succeeded in producing a book that will prove of large service.

**FIRE PREVENTION AND FIRE PROTECTION.** By J. K. Freitag. 1017 pp. Ill., index. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$4.

After a study of this volume, it should be said that it ought to be in the hands of everybody contemplating erecting buildings, also of architects, contractors, and insurance companies, especially in San Francisco. Although of considerable length, the work has been published in convenient form, so that it will easily fit into the pocket, and be handy for reference. Chapter I deals with the annual fire losses in the United States, which have been around \$200,000,000 for some time, some detail being given to the conflagrations at Chicago, Baltimore, and San Francisco. Chapters II and III argue on the theory and practice of fire prevention and protection, and on fire insurance. In the latter case, instructions or suggestions are given how to insure certain buildings. In chapter IV the slow-burning or mill construction is discussed, with many diagrams and details of buildings. Part II contains 80 pages on fires in fire-resisting buildings and conflagrations, and shows the result of fires in certain buildings, even as recent as the Equitable affair in New York, besides much detail to the fire in San Francisco, and lessons learned therefrom. On the manufacture and use of fire-resisting materials much valuable information is given. Part III of the book covers fire-resisting design of buildings, inside and out, details of floor and window construction, and results of many fires. In this section, the architect should find everything required for making a modern building fireproof. Part IV deals with fire-resisting construction in like manner. Special structures, such as theatres, schools, and factories, where fires often result in great loss of life; safes and vaults, which are for the purpose of protecting valuables, coin, and documents from fire, water, and impact of falling bodies; and garages demand special construction, which are shown in part V. Part VI considers much important auxiliary equipment and safeguards, as sprinkler systems, automatic fire-alarms, watchmen, standpipes, and hose; inspection of fire-protective devices; and fire-drills. Altogether, this is a valuable work on an all-important subject.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice or mining, milling, and smelting.

**S**NOW fell at Sucre, Bolivia, in July, creating a sensation and upsetting all traditions.

**M**ACHINE drills at the Alaska Treadwell mine averaged 29.6 ft. per day, and 34.4 tons broken per day, during 1911.

**L**AUNDRY machines are used at the United States Treasury to wash dirt out of money; a reversal of the miner's process of washing gold out of dirt.

**D**RILLING contests at the annual picnic of the Butte miner's union, resulted in a team from Arizona drilling 43 $\frac{3}{8}$  inches in 15 minutes into granite, followed by a Butte team with 41  $\frac{11}{16}$  inches in the same time.

**A**IR-RECEIVERS accumulate oil from compressors, and explosions have resulted from this, showing that the receivers ought to be cleaned out periodically. The mining regulations in Western Australia enforce this work.

**S**PITZBERGEN is an interesting island, north of Norway, in that it is under no special flag, and contains coal and marble. The American-owned coal mines will produce about 60,000 tons for the year; and an English company is to quarry marble for export.

**G**RADING TESTS on certain ores by wet and dry methods have shown differences of 2% in accuracy in favor of the former. In the latter method, particles of ore become coated with extremely fine dust, which will not shake off; whereas in the former this is washed off by the water used during screening.

**G**NATS are especially troublesome at Copper River district of Alaska this season, as they generally are in the North. Many parts of Australia are troubled with flies, while mosquitoes are a nuisance in tropical countries. Mining regions are usually in outlandish enough parts, let alone being troubled with such pests.

**I**TALY imported in 1911 metals valued at \$113,000,000. Pig iron amounting to 232,811 tons was imported, and scrap iron, 392,703 tons. Of the latter, only 12,658 tons came from the United States, there being strong competition with European producers. Sulphur exports totaled \$7,917,880, of which \$174,279 went to the United States.

**F**LUORSPAR is found in crystals, generally cubical in color, ranging from a clear slightly bluish or green glasslike tint through various other brilliant colors to dark purple, although much of it is white and opaque. Associated with others minerals, fluorspar has a broad distribution, but deposits of workable size are not abundant, the deposits thus far exploited in the United States being found only in the states of Arizona, New Mexico, Colorado, Illinois, Kentucky, Tennessee, and New Hampshire.

**I**RIDIUM is a rare metal, not more than 5000 oz. being produced annually, of which about 500 oz. are recovered in the United States, mostly from imported platinum sand, and copper ores and bullion. Prices ranged in 1911 from \$60 to \$64 per ounce for pure metal. Iridium finds a fairly extensive use in the points of fountain pens, in standard weights, pivots, and contact points. An oxide of the metal, iridium black, is valuable as a pigment for decorating chinaware. According to the Bureau of Statistics, 3905 oz. of iridium, and iridium in native combination with platinum metals, valued at \$210,616, were imported into the United States in 1911.

## Motor Truck Tests in Army Maneuvres

Two important army tests in which Mack and Saurer trucks have been conspicuous in the summer of 1912 were the National Government maneuvers in Iowa and Wisconsin held early in June, and the Connecticut maneuvers recently brought to a close.

The western maneuvers were made over a route that was especially constructed for the difficulties of operating motor vehicles, and in these tests trucks of from 1 to 3 tons live-load capacity were employed. The object of the tests was to determine how far from the base of supplies the army could be maintained with trucks as a means of transportation, likewise to ascertain the practicability of motor trucks operating over irregular highways; that is, crossing fields and maneuvering through timber and brush. The regulations were exactly the same as would prevail in actual warfare. Regular highways were never used in transporting supplies, and naturally these regulations caused many difficulties.

The International Motor Co., New York, had two entries in the western maneuvers—a Mack standard 1½-ton truck and a Saurer 5-ton model. The Saurer was the same type of machine which has competed annually for the French war department subsidies since 1904 and which has never failed to win the first honor in its class in the European trials.

The Mack 1½-ton truck was used as a substitute for the regulation camp wagon and followed the mule-drawn wagon in the line of march, and as the infantry set the pace which could not be exceeded by the truck, it is obvious that this was a very exacting test for a light type truck to run three or four miles an hour as a steady pace.

The Saurer truck was used for carrying the supplies between the army's base and the command, and its mileage was increased by twelve each day for the distance covered by the command.

In the New England army maneuvers recently completed there were two Saurer trucks entered, one the famous 'Ocean-to-Ocean Pioneer Freighter,' the first commercial car to cross the continent. This truck has been running constantly in demonstrating work in New York since its famous journey made in the summer of 1911. The fact that its manufacturers were confident enough of its staunchness after the strenuous work in which it has already been put to enter it in the army maneuvers that were designed to particularly test the hardihood of a motor truck, indicates the faith which Saurer advocates have in their 'slogan,'—'In more than 17 years no Saurer has ever worn out.' The Saurer pioneer freighter was employed for handling baggage, camp equipment, tents, etc., and it was constantly overloaded during the New England maneuvers to at least 25%. In the report, the driver of this truck says that on the first day's run to Bridgeport, Connecticut, there were no road difficulties, and everything went along nicely until they reached Tyler City camp, after which there was a succession of bad bridges, sandy roads, and heavy rains. Under the stress of the heavy going, the pioneer freighter was one of the few trucks entered that was not delayed by mud and breaking through bridges. The New England maneuvers were designed particularly to test the hill-climbing ability of trucks carrying full loads, and the two Saurers are claimed to be the only two trucks in these maneuvers that surmounted the hills over which the army marched. The reason for the ease with which the Saurer climbed the grades is the fact that it had its origin in the Swiss Alps, where the grades are much steeper than they are anywhere in the United States except in the Far West, and also because the light weight of the chassis of the Saurer truck enables its engine to exert its power in propelling the load and not in pulling the dead weight which with most trucks is the greatest drawback.

The Sixth Annual Employees' Outing of the DODGE MANUFACTURING CO. of Mishawaka, Indiana, was held August 22 at Springbrook Park, Indiana.

## New Type Spiral Riveted Pipe

The Standard Spiral Pipe Works, 25 North Dearborn street, Chicago, is placing on the market a reinforced galvanized spiral pipe which is made from two strips of steel of different widths and with a continuous interlocking seam. Both strips of steel are rolled to shape on the edges and are interlocked and rolled down under very high pressure in a special machine which this company has patented. The strips of steel are first cut the required width from long sheets of steel and the ends are welded together. The steel is then placed on large spools. The strip used for the outside or reinforcing band comes from the steel mills in long lengths on reels. Both these strips are fed into the machine at one end, rolled down and interlocked in the machine, coming out at the other end in the shape of pipe.

This pipe is smooth on the inside and has the reinforcing band running on the outside the full length of the piece, and can be made endless. This strip is not welded or soldered on the pipe, but is interlocked in the form of a continuous seam. Ample folds are made on both strips, so that a large bearing surface-contact is obtained at the seam. The advantage of this reinforcing band and smooth inside can readily be understood by engineers and others who have hitherto had to contend with frictional resistance met with in riveted pipes.

A soft open-hearth steel is used which will stand the required bending, and the steel is not weakened by being punched full of holes near the edge, nor is there one per cent as great a possibility of this pipe leaking as that of any riveted construction. In winding the steel into the spiral form, advantage is taken of all the tensile strength and stiffness which the material has, and lighter gauges of the pipe can be used for pressures that would require considerably heavier gauges by any other method of construction.

It will also be noticed that in the construction of reinforced galvanized spiral-pipe there are no rivet-heads protruding on the inside, but the pipe is smooth inside, and therefore has the least possible frictional resistance to the flow of water and other substances, and will not allow particles to adhere to the inner walls of the pipe, and thus gradually reduce the diameter and increase the friction. Its lightness enables it to be moved from place to place and to be installed in difficult places of access.

It will be noticed that at the point where the reinforcing band passes around the pipe, there are four thicknesses of metal. A number of bursting tests have been made on this pipe. One at the Armour Institute with a piece of 18-in., No. 20 gauge, reinforced galvanized spiral-pipe. It required 235 lb. hydraulic pressure to burst the seam. From this it will be noticed that the efficiency of the joint is very great. Another was made on a piece of 16-in., No. 20 gauge, where the hydraulic pressure was raised up to 320 lb., at which the wide band of steel between the two seams commenced to bulge out, and actually expanded three-quarters of an inch in diameter. The pressure was then turned off and a section cut out of the pipe, and it was found that the seam had not been affected in the least. There was no sign of fracture or opening of the seam either on the inside or on the outside.

Standard reinforced spiral-pipe can be supplied in any required length up to 20 ft., galvanized, and asphalted in any required length up to 25 ft. Price-lists and further information can be obtained and estimates on any quantity will be gladly submitted.

R. B. HUTCHINSON, formerly manager of the smelter in Chihuahua for the Rio Tinto Copper Co., and recently manager for Corrigan, McKinney & Co. in Mexico, will open an office for consulting practice at El Paso, Texas. Norval J. Welsh will be associated with him.

The CANADIAN COPPER CO., Copperliffe, Ontario, has ordered a Ruggles-Coles class F-8 dryer.

## EDITORIAL

**C**ONDITIONS in Nicaragua are much quieter and it is hoped that peace plans can soon be promulgated.

**D**IVIDENDS of the Anaconda Copper Mining Company have been increased 25 cents per share, as a reflex of the rising price of copper.

**M**EMBERS of the American Institute of Mining Engineers should not neglect to send proxies to be voted at the meeting in New York on October 7.

**I**NDIA has begun to ship pig iron to Japan, the cheap price of the rather low-grade pig and the less freight as compared with European ports proving attractive to the Japanese consumers.

**T**IMES change but human nature never. The coopers' union is protesting against the substitution of steel for wood in the casks used by the Standard Oil Company, as did the weavers against the introduction of steam-driven looms in England.

**M**AIL for Yukon points by way of White Horse closed for the season on Monday with the departure of the *City of Seattle* from Seattle. Later mail will have to be handled from coast points by dog team. The last steamer for Nome and St. Michael departs early in October.

**D**EFINITE facts are the most elusive of abstract bodies and an otherwise readable article is often weakened by their absence. Our readers will be correspondingly grateful to Mr. Charles Janin for their free use in his admirable discussion of dredging on the Seward peninsula, and his example is one that may well be emulated by authors.

**C**ELEBRATION of the twenty-seventh anniversary of the achievement of the classic burro was quietly made by the Bunker Hill & Sullivan Mining & Concentrating Company on September 10 by declaring dividend No. 180. Its record of \$13,715,550 paid in dividends is an enviable one, and speaks eloquently of an excellent mine under excellent management.

**F**INAL cancellation of the Cunningham claims comes as no surprise, as it is merely the formal action following the previous decision of the Secretary of Interior. There seems now little hope that the claimants will ever receive either the land or the return of their money, and however much we may favor a change from the old policy of distributing the public lands, this is a substantial injustice that should be remedied.

**M**EXICAN commerce has suffered remarkably little from the political disquiet of the past year, reaching a total of \$240,000,000, as compared with \$250,000,000 the preceding years. The export of mineral substances increased \$3,000,000 despite a decrease of \$2,500,000 in the yield of gold bullion, since silver exports increased nearly \$4,000,000 and copper nearly an equal amount. Our neighbor is prosperous even if disturbed.

**EXCURSIONISTS** from the Eighth International Congress of Applied Chemistry will reach San Francisco next week and are to be entertained by the local members of the American Chemical Society on Tuesday evening, October 1. An excellent opportunity for promoting acquaintance with the foreign members will thus be afforded.

**OBSERVERS** profess to detect the hand of Standard Oil in the new loan which Mr. A. W. Jackson has floated for the republic of China. The rate is high and the situation is almost too complicated for comment. Another side of the picture is seen in a protest, made to the President, that the operations of a mine some distance from the tombs of the Ming Emperors are disturbing the shades of the illustrious dead.

**GOLD** imports of \$750,000 have been received at New York during the week, and other consignments are expected. These are the first gold imports in some time past. Early in the month New York municipal  $4\frac{1}{2}$  per cent bonds fell below par, and the same downward tendency is observable in other municipal bonds. The demand for capital has become so great that a high interest yield must be afforded to attract investors.

**KATANGA** copper matters are now under the direct control of the Belgians. It is said they have sent out as manager an engineer experienced in coal mining; a rather peculiar choice, since the problem is essentially metallurgical. The cheap smelting of silicious copper ore, in the absence of sulphides, is yet to be accomplished. The new manager is reported to have got at the heart of things promptly and announced that coke consumption must be reduced. Exactly, but how?

**ELECTION** of Mr. G. A. Denny to the presidency of the Mexican Institute of Mining and Metallurgy is a well-deserved honor which reflects credit upon the Institute as well. Mr. Denny has had varied experience in the far parts of the earth, and his work, in collaboration with his brother, while consulting engineer for the General Mining & Finance Corporation, is well known. The Mexican Institute, like its American analogue, has difficulties of a financial nature, and it is to be hoped that they may be as speedily adjusted.

**COMMERCE** of the United States in August exceeded that of the corresponding period in preceding years, both in imports and exports. Imports reached \$155,020,792, an increase of \$30,000,000 over the preceding year, and \$17,000,000 more than in 1910. Exports were valued at \$167,885,095, an increase of \$26,000,000 over 1911, and \$36,000,000 more than in 1910. Dividends and industrial disbursements by railroad, traction, and industrial corporations during October are estimated at \$174,579,000, an increase of \$11,000,000 over last year. And yet people believe that a presidential year is a bad one for business.

**CESSATION** of work by the miners of the Utah Copper Company was announced in our news columns of last week. The miners, few of whom were union men, were persuaded by officials of the Western Federation of Miners to strike to enforce a demand for an increase of 50 cents per day in the rate of pay. Complaint was also made by the Greek miners against an employment agent of the company, and his resignation has been accepted. Recognition of the union has been made an issue, and 1000 miners are said to have joined since the strike began. The miners at first took possession of the property, but by the prompt and wise action of the Governor of Utah, were peaceably persuaded to evacuate their stronghold. Both sides are still firm. Some of the possible aspects of the case are indicated

by our New York correspondent, who speculates on the effect on the copper market. It is no less interesting as an evidence of the growth of concepts regarding the profit sharing of corporations with employees. The price of copper has increased over 40 per cent during the past year, and the workmen are not satisfied with the 10 per cent increase of wages granted them on September 1. But the difficulty of sharing prosperity with employees is that they are not prepared to accept a corresponding decrease in wages when prosperity departs. The Utah Copper Company has done admirable work and will doubtless meet this difficulty as well as it has preceding problems.

**NOTABLE** contemporaries have recently elaborated anniversaries. *The Times*, of London, on September 10 commemorated its forty-one thousandth issue by a special number dealing with the development of printing and newspaper publishing, on which so great a journal can be expected to speak with authority. The *South African Mining Journal* celebrates its twenty-first birthday with an issue reviewing two decades of progress on the Rand, while the tenth anniversary of *Chemical and Metallurgical Engineering* happily coincided with the meeting of the Eighth International Congress of Applied Chemistry in New York. Our excellent contemporary, *The Canadian Mining Journal*, devotes its issue of September 15 to the mines and minerals of Nova Scotia. Though but a stripling to *The Times*, we have already rounded the half century, and with the privilege of maturity we commend our juniors for the excellent work they have done, and wish them a continuation of the prosperity they have deservedly enjoyed.

### The Institute and Its Members

In the consideration of many details fundamentals are frequently obscured. During the past year many communications have been addressed to members by officers and committees of the American Institute of Mining Engineers, and on another page several of the more recent are reproduced. In the discussion of Institute affairs which has been in progress for many months two topics have been to the fore; the proposal to increase the dues, and the land debt of the Institute. Whether from their stimulus to the pocket nerve, or because they are easily grasped, these topics have occupied an undue share of attention. As Mr. Charles Kirchhoff points out, the Institute has always been able to meet its ordinary expenses from its ordinary income, and no increase is now necessary except to meet the interest charge and repay the principal of the land debt, which has already been reduced by subscription to \$68,000. The recent appeal sent out by Mr. James Douglas has brought responses from 233 members, and \$12,800 additional has been pledged, thus reducing the debt to \$55,200. Further subscriptions will doubtless be received, and the plan proposed by the San Francisco members of temporarily increasing the dues of those members who prefer not to subscribe, will adequately meet the situation. Out of the total membership of the Institute, 500 members have already subscribed \$125,000 toward the land debt of \$180,000, and the others should not be slow to do their part. Subscriptions are more effective than yearly payments, since they lighten the present interest charge of \$2720 on the debt, and \$20 per member from the majority who have not yet contributed will amply meet the situation. In spite of the experience cited by Mr. H. V. Wheeler, in our 'Discussion' columns, we deprecate an increase of dues. The Institute has been able to do admirable work on its former income, and the proposed increase would tend to cause young engineers to postpone joining the Institute, and bear heavily upon some of the present membership.

Questions of finance are, however, but minor considerations, the essential problems are many, and, in our opinion, they centre about the difficulty of awakening the members to a sense of their duties, privileges, and responsibilities. The Institute is an association of mining engineers and metallurgists, formed for their mutual benefit. The Directors and the Council are trustees and servants for the membership. Unless the members take enough interest in Institute affairs to know what they want and why they want it, and communicate their wishes to the Council, they alone are to blame if the Institute does not fully meet their needs and desires. In calling the meeting at San Francisco to discuss these matters, postcard notices were sent to 175 members, but only 15 attended the meeting. Presumably, those who were interested enough to come were those best informed, yet it was evident that many of those present had forgotten the purport of the communications sent them on Institute affairs, if indeed they had ever read them. This is the root of the whole matter. The Institute should be a society, not a publishing house. No amount of effort by a few men can make a society useful and effective unless the membership interestedly participates. At the meeting in New York on October 7, and at the general meeting at Cleveland next February, questions of general policy will be acted upon; reclassification of membership, formation of local sections, consolidation of the Mining and Metallurgical Society with the Institute. If the action taken does not suit you, Mr. John Smith, it is because you have done nothing for the Institute beyond paying dues and reading the *Bulletin*. More needed than a subscription by each member toward the principal of the land debt is a contribution of interest toward the funded *esprit* that constitutes the greatest asset the Institute has or can possess.

### The Lure of Mystery

In the old-fashioned novel, which Kipling has called the three-decker, young men who wished to make themselves irresistible to the other sex would assume an air of settled melancholy and make vague references to an incurable and secret sorrow which darkened their lives. In the story this procedure was always effective. In these less sentimental days, buccaneer captains of industry often utilize the same psychological phenomenon—the lure of the mysterious—in selling shares in enterprises organized to recover buried treasure or bullion lost in sunken ships. More originality in playing upon human weakness was exhibited by Walter Scott, better known perhaps as ‘Death Valley Scotty,’ who in devising romantic fiction concerning non-existent mines showed himself an able even though unworthy bearer of the name. For years his doings furnished ‘copy’ for the journals that pander to the craving for excitement. Early last June there appeared in one of the Los Angeles papers an advertisement, illuminated by a photograph of Scott, stating that he had disposed of his claims in Death Valley to a local syndicate for “a million dollars,” and that a corporation, to be known as the Death Valley Scotty Gold Mining & Development Company was in process of formation for their exploitation.

Through the efforts of the Los Angeles Chamber of Mines and Oil, stimulated by its secretary, Mr. G. M. Swindell, the following romantic but sordid story was disclosed.

Several years ago Messrs. Burton Gaylord, of Los Angeles, and A. M. Johnson, president of the National Life Assurance Company of Chicago, provided Scott with \$5000 in cash, and paid for the special train in which he made his record-breaking trancontinental trip. This arrangement was made with Scott contingent upon his divulging the

situation of his claims in Death Valley upon his arrival in Chicago, when he would be paid an additional \$5000, and given a substantial interest in the company to be formed for the exploitation of his property. As Scott had nothing to divulge, nothing happened; and he arrived in Barstow on his return with about \$12. Mr. Johnson, however, proved sufficiently credulous to continue for several years to provide him with sufficient funds to enable Scott to ‘splurge’ occasionally; and, later, the Girard family of Philadelphia became interested, and were also mulcted of several yearly payments. A story, probably fabricated by Scott and elaborated by his friends, is to the effect that his backers planned to send Scott, at the proper time, with an armed guard, in charge of about a ton of high-grade ore, by special train from San Francisco to New Orleans; thence by boat to New York City, where the ore, with an assay certificate, was to be placed on display in Tiffany’s window. A \$15,000,000 corporation was to be formed, with shares of the par value of \$100, no certificates being issued for less than ten shares. It is pleasant to contemplate the eagerness with which investors would have parted with their hundred-dollar bank-notes to purchase blocks of this stock.

Early in 1912 Scott opened negotiations with Messrs. F. C. Goodin and Frank Sharp for the purchase of his alleged properties, and claimed to have received \$25,000 from them on June 1 as first payment on his claims. When this statement was published, Dr. C. W. Lawton, who has a judgment against Scott for \$1000 for professional services, haled him into court as a judgment debtor. In his usual spectacular manner Scott declined to tell what had become of the money he was supposed to have received, saying he “didn’t keep books in his business.” After maintaining this attitude for several days, he was finally committed for contempt.

Meanwhile the Los Angeles Chamber of Mines and Oil had become active in the matter, and learned that the company had no claims, that its representative was to go with Scott to Death Valley and locate everything within a radius of ten miles, Goodin remarking that they “wanted the fakir kept as far away as possible.” The results of the Chamber’s investigation were presented to the District Attorney, with a memorandum as to Scott’s past. Mr. Samuel E. Browne, chief of detectives, played upon Scott’s feelings so that he finally admitted that he had been paid but \$200 for signing a receipt for \$25,000, which was to be used in the exploitation of the company. Meanwhile, Goodin and Sharp had been served with subpoenas to appear before the grand jury, and a similar writ issued for Scott. He admitted before the grand jury that he had been paid but \$200 for signing a \$25,000 receipt, stating voluntarily that he had never owned any mining property, and that he had never had more than \$200 in high-grade ore in his possession at any one time. He denied, however, that he had ever acted as a go-between for ‘high-graders,’ though he confessed that he has often bought high-grade ore for use in what he termed his ‘grand-stand plays.’ Truly a pitiful ending to a career made national as a result of the free advertising accorded by sensational newspapers.

Goodin and Sharp were indicted for perjury and are in course of trial. The greatest credit attaches to the members of the Chamber of Mines and Oil, and especially Mr. Swindell, for their successful efforts in unmasking make-believe. Chicanery, exaggeration, and misrepresentation have too long been associated with certain kinds of mining finance. When mining men generally are more ready to discountenance and oppose such methods of promotion, mining will be less commonly confused with gambling by the general public.

## Gold Dredging on the Seward Peninsula

By CHARLES JANIN

Gold dredging has become the most important branch of the mining industry on the Seward peninsula. This is due in part to the almost total cessation of winter drift mining and the decrease in the number of mining operations except dredging. The dredges operating in 1910 had, with some exceptions, a successful season and greatly encouraged further construction. In 1910, 16 dredges were operating on the Seward peninsula, in 1911 there were 22 at work, and during 1912 there were working, or in various stages of construction, 39 dredges in all, though some of these will not be finished until 1913.

The first dredge to operate on the Seward peninsula

is that shown in the accompanying illustration. One can picture the machine charging down the beach into the surf, dropping the goose-neck suction arrangement, and then commencing to "draw the yellow metal," the man in charge keeping one eye seaward ready to up anchor and away at indications of heavy breakers. Needless to say, the yellow metal secured by such machines was obtained by using them as a magnet to draw it from the pocketbook of the credulous investor, yet I understand that a machine of similar type is now being built at Nome.

While, as in other localities, numerous failures marked

WISCONSIN DREDGE IN ACTION.

was the Wisconsin, which was put on the Snake river, near Nome, in 1899. This was not a financial success and did not operate long, but the dredge is still in existence. I photographed the boat when in Nome, but it is more interesting to show evidence that the dredge really operated, so I secured the picture reproduced here showing the old boat in action. A dredge operator told me that previously to putting a dredge on his property he had serious thoughts of buying and repairing the Wisconsin. The owners, however, fortunately for him, asked more for the old boat than he was willing to pay. With the practical experience gained from operating his present dredge he now congratulates himself that he did not "fall" for the Wisconsin. Around Nome there are the remains of many peculiar machines which were designed to win gold from the beach or creek gravels, that serve to show the ignorance and optimism of the first arrivals as well as the credulity of the investors in these enterprises.

many of the early dredge installations, and while a number of the dredges now operating are not a financial success, dredging at the present time is the most important factor in the gold production of the Seward peninsula, the total gold production for 1911 being \$3,100,000, of which nearly one-half was won from dredging operations; during 1913 a number of additional boats will probably be arranged for, and it may be expected that a still larger proportion of the total gold production will be obtained from the dredges.

Although practically all the mineral production of the Seward peninsula is derived from gold placers, some profit has been made from the tin placers on Buck creek, and the dredge of the York Dredging Co. is a profitable enterprise. This enterprise has been described by H. G. Peake (*Mining and Scientific Press*, p. 652, 1911).

Dredges start about June 15, or shortly after the arrival of the first steamers in Nome, and stop at the close of the season, in time for the crew to leave on the last boat out.

Those dredges employing local men start a little earlier in the season and work a few weeks later, but one of the operators, who started his dredge in May, stated that he

thought there was little profit to be made by starting before the spring frost was out of the ground. Some of the reasons for the failure of certain dredges may be mentioned:

erty that has not been prospected, (5) high power cost, and (6) poor management; which also probably covers several if not all of the items above.

\*\*proposed dredge.

(a) Open-connected.

(b) Close-connected.

(c) Tin dredge.

(d) Flume dredge.

(e) Not operating.

(f) Have changed fuel to oil this summer, but not sufficient data obtainable as to results of new fuel.

(g) Power generated from oil.

To the man shoveling gravel into a sluice-box, a few acres undoubtedly looks like a large piece of ground, and probably seems sufficient to warrant building a dredge, but some of the dredges built in Alaska seem as large as the property for which they were constructed. This is a disadvantage that has been overcome, in one instance at least, when there was another property in the vicinity to which the dredge could be moved after working out the first area. Moving a dredge is not generally considered a simple matter by those accustomed to the heavy California type dredge, built to dig ground 30 to 60 ft. deep. With the

washed. Mr. Saupe expects to build a dredge better adapted to frequent moves, and which can be used to advantage on areas otherwise too small for the individual dredge, but containing sufficient gold to make such a procedure profitable.

A problem that has attracted much attention in recent years is the possibility of commercially thawing the deep ground; occasionally items appear in the technical and daily papers to the effect that a dredge is to be built to work ground in Alaska from 60 to 100 ft. deep; one such item of 'news' being of recent occurrence. Most of

THREE FRIENDS DREDGE, BUILT BY WESTERN ENGINEERING &amp; CONSTRUCTION CO., AND EQUIPPED BY THE BUCYRUS CO.

flume dredge, that has been proved successful on shallow ground under favorable conditions in Alaska, it is a different matter. The Kimball & Saupe dredge operating on Melsing creek worked out the property for which it was built, and the owners moved the boat to 24 Ophir, about ten miles distant. The total cost of moving and reconstruction, according to the owners, was approximately \$3000, which seems a low figure for the work involved. This is an important feature in dredge construction in the Far North, and one that is readily appreciated by those familiar with conditions there. The flume dredge is simple in construction and works well where the gravel is easily

the ground this dredge is intended to work is permanently frozen, and as the gold content claimed is only 39c. per cubic yard, it is not difficult to prophesy the ultimate result of the enterprise. Thawing shallow frozen ground, from 14 to 25 ft. deep, for dredging is successfully done in the Yukon, and in a small way in the Seward peninsula. Some time ago the Blue Goose company on Ophir were obliged to thaw occasional small spots of frozen ground ahead of the dredge. The cost of doing this, according to Gilbert Russell, who was then manager, was 40c. per cubic yard. Blasting was tried, but was successful only where small patches of frozen ground overlay thawed ground. State-

ments have been made by interested parties to the effect that permanently frozen ground 50 ft. deep near Nome had been successfully thawed and dredged, but this I found out was not the case. The only place where thawing is carried on ahead of dredging near Nome was that done by Mr. Plein on Otter creek. Mr. Plein uses a 35-hp. boiler, which supplies 18 points and consumes 330 gal. of crude oil per day; oil costs \$3 per barrel delivered. The ground being thawed at the time I visited the dredge was from 6 to 8 ft. deep, and the cost of thawing, according to Mr. Plein, was 20c. per cubic yard. With greater depth it becomes increasingly difficult to penetrate the ground with the steam-points, and in districts with higher fuel costs the expense of thawing would be proportionately increased.

One would think that by this time investors would have become sufficiently enlightened to demand that a property be prospected before purchasing a dredge, but this is not always the case. In fact, in Alaska it seems to be the exception and not the rule to prospect a property thoroughly; the parties interested evidently preferring to do their prospecting with the dredge, as in several areas in Seward peninsula practically the only prospecting was done after the dredge was built. By some miracle, one of the dredges so installed, I have been told, happened to be on ground containing sufficient gold to pay operating expenses, but it is doubtful if the return of the investment will be secured. To say the least, the policy of prospecting the ground with a dredge cannot be considered good practice, and cannot be too strongly condemned. The number of failures in Alaska dredging should impress the investor of the future that ground should be first thoroughly prospected by a competent engineer before a dredge is constructed. The larger dredge construction companies are recognizing this, and do not encourage the drawing of hasty conclusions about a property. The two largest dredge concerns in the United States have had an engineer investigating this field, and making a study of the obstacles that must be overcome to make dredging a success. The fuel problem is a matter of great importance, and the high cost of fuel at the dredge accounts, in great measure, for the high operating cost as compared to dredges in more favored districts. In Alaska, as elsewhere, the operating cost is not always freely given by the operator, who at times is himself ignorant of the real cost of operating his boat. In the matter of yardage handled by the boat, the man in charge is sometimes gifted with a generous imagination; one operator claiming a capacity for his dredge in excess of the theoretical capacity of the buckets. It is not to be wondered that operators getting such yardage as this sometimes obtain a low operating cost per cubic yard.

All dredge operators in Alaska are not, however, of the class mentioned. Some discuss questions of cost freely and are constantly trying to improve methods. Some facts that militate against low costs are the short operating season, the high wages paid, the scarcity of good men, and the inexperience of those in charge, a number of instances where considerable saving could be effected being noticed on some of the dredges visited. Few dredges keep yardage records by bank measurement, and itemized expense accounts; none that I saw attempt to figure depreciation, and as for amortization, there are some operators who do not understand what the word means, much less how to make use of the principle.

To show the difference in power costs in the Far North as compared to California fields, the following will be of interest: In a table\* I prepared, showing operating costs of dredges in California, the cost of power for dredges using electricity ranges from 0.41 to 2.02c. per cubic yard, the latter being that of a 5-ft. boat working on partly cemented gravel. On the Seward peninsula electricity is available for only two operating dredges, the Bourbon and the Wonder, being generated at an oil-burning plant on the Bourbon property. Figures of power cost were not obtained from these boats, if indeed they are kept; the enterprise not being a financial success, and one that has been

subject to considerable criticism in the past. Various schemes have been proposed to generate power at a central station for dredges in the vicinity of Nome, but nothing beyond the Bourbon plant has been attempted. Some of these schemes involved using a steam plant, while others were more ambitious and were based on the utilization of water-power at a considerable distance, with long transmission lines to the Nome district. When a company is operating only one dredge the installation of a plant to generate electricity is rarely feasible, and it is doubtful if at the present time a central plant to generate electricity would be a profitable enterprise.

The use of gas-engines has demonstrated that a great saving can be made in the cost of fuel compared to dredges using coal, wood, or crude oil when transportation for any distance from the seaport is necessary. Several boats have been changed from coal to oil-burners this summer, and a considerable reduction in the fuel costs is expected. The new arrangement has not been in operation, however, long enough to obtain figures of any value.

I have shown in the table accompanying this article the approximate amount of fuel used by the different dredges, but the following more fully elaborates the matter. In making comparisons with outside dredges it must be borne in mind that these are not power costs, but fuel costs only, as they do not include labor, etc. The Plein dredge burns 14 bbl. of oil per day, at a cost of \$3 per bbl. at the dredge. With an average daily capacity of 800 yd., the cost for fuel thus indicated is 5.25c. per cubic yard handled. The operating costs of this dredge, according to Mr. Plein, were 16c. per yard, with thawing costs of 20c. per yard additional. The Three Friends dredge has the unenviable record of having the highest fuel costs on the peninsula, with the exception of the Osborne Creek boat, but not excepting the wood-burning Blue Goose. The reason for this was that the Three Friends boat, through a mistaken idea of economy at the time it was built, was equipped with slide-valve engines and locomotive boilers. The coal consumption varied from 12 to 17 tons daily, costing about \$22 per ton at the dredge. Accepting 14 tons at \$22 as an average daily consumption, the fuel cost is \$308. The average daily yardage for 1911 was 2000 cu. yd., so the fuel cost thus indicated was 15.4c. per cubic yard. The total operating costs are not made public, but were said by some one familiar with company details to have been in excess of 35c. per cubic yard. This year the management changed to oil fuel, and had just installed oil burners the day I visited the dredge. A considerable saving in fuel costs is expected, but in my opinion a more economical arrangement would be for the company to dump the fuel-eating locomotive boilers overboard and put in suitable up-to-date machinery.

The Solomon dredge, which has a capacity somewhere approaching that of the Three Friends dredge, but is a better equipped boat, handled an average of 1800 yd. per day for 1911. This dredge consumed 7 tons of coal per day at \$27 per ton, or \$189, representing a fuel cost of 10.5c. per cubic yard. This dredge has also been changed to use oil for fuel, and a considerable saving is computed by the manager, who states that oil could be delivered to the dredge for \$4 or less per barrel, on account of an arrangement entered into with the Three Friends company, whereby the two companies erected a storage-tank at Solomon and arranged to buy a considerable quantity of oil at a time, thus securing more favorable prices. The Nome Montana fuel cost, as computed, is approximately the same as that of the Solomon. The Blue Goose dredge burns from 7 to 10 cords of wood, costing \$12.75 per cord. The dredge averages 800 to 1000 yd. per day; assuming a fuel consumption of 10 cords and the yardage handled at 1000, the cost per cubic yard for fuel would be 12.7c. The Blue Goose is one of the most interesting dredges on the peninsula. Originally built by I. B. Hammond, it has been completely overhauled until the equipment bears but little resemblance to that of the original boat. It has so-called 5-ft. open-connected buckets which, however, are only about 4 cu. ft. actual capacity; the buckets dump into a hopper feeding a sluice

\*Mining and Scientific Press, July 30, 1910.

22 ft. long, fitted with cast iron riffles, which catch about 65% of the gold recovered. From the sluice the gravel passes to two shaking screens placed tandem, each 15 ft. long, and from these screens to a belt-conveyor tailing-stacker. One of the most agreeable features of the dredge to the visitor as well as the crew is the cuisine, a veritable Hamburg-American service directly on the boat. Here I enjoyed the best meal I had during my stay on the peninsula. Tom, the Japanese cook, is allowed \$1.50 per day for food, and seems to exercise rare judgment in catering. No complaints of the food served are heard on the Blue Goose, which differs in this respect from some of the mining camps I visited.

The Wild Goose dredge burns about 300 gal. of distillate, costing 25c. per gallon. With an average of 1800 cu. yd. per day a fuel cost of 4.2c. per yard is indicated. The Wild Goose is the most successful dredge on the peninsula. It has a 3½-ft. close-connected bucket-line and was built by the Yuba Construction Co. Some difficulty has been experienced with the engines, but they have been thoroughly overhauled this year and some other changes made, among which may be mentioned an 8-ft. extension to the dredge ladder.

The Osborn Creek dredge was first built on Lower Dry creek at Nome. This ground had not been prospected before the dredge was built; a too frequent practice mentioned elsewhere. When the boat was ready to run it was found that a great part of the ground was permanently frozen and too low grade for profitable dredging. The dredge was afterward moved to Osborn creek, about 12 miles distant. The machinery was first removed and the hull sawed in half and hauled in sections. A section weighed 55 tons and was drawn by 66 horses. This dredge has not been a profitable enterprise, and is in the hands of a receiver appointed for the benefit of its creditors. The fuel cost, as mentioned previously, has been the highest on the peninsula, due in most part to inefficient handling. Two locomotive boilers supply power, and crude oil is burned. The consumption, or rather the consumption plus loss, was 1 drum of oil, costing \$15, per hour when running; two teams would not have been sufficient to keep the dredge supplied with oil had it not been for the frequent stoppages of the boat. The company engaged William Colley, one of the Union Construction company's superintendents, to overhaul the oil-burning apparatus this summer, with the result that a saving of about 40% in the fuel used was effected. Other fuel costs could be quoted, but these examples serve to illustrate the different fuel costs and the advantage of distillate over coal, wood, or crude oil. The small dredges burn about 120 to 190 gal. of distillate per day, their fuel cost ranging from 4c. per cubic yard up, according to the capacity of the dredge and the price paid for oil. Some operators purchase their oil in cases, and others in drums; the case oil is more expensive, and is subject to a higher percentage of loss through leaks, while shipping in drums necessitates an initial outlay for the drums.

The matter of freight, as stated elsewhere, is a serious problem. Summer freight costs, according to the principal dredge constructor, in Alaska can be figured roughly at \$1 per ton per mile. Fuel oil in drums is figured by freighters as 2 drums to the ton, and in cases at 25 cases to the ton, the one being 0.45c. per mile per gallon, the other 0.4c. Distillate costs in San Francisco approximately 9c. per gallon in drums and 16c. in cases; \$8 being charged for the drum and rebated on its return. Steamer freight charges on oil are the same whether shipped in drums or cases.

In addition to the placer examinations on which I was engaged, there were a number of other examining and prospecting parties in different localities, and there are several proposed dredge installations on the Seward peninsula other than those I have noted in the table. Aside from those dredges that have been built for property unsuited for dredging, the results for 1912 will probably encourage further dredge equipment, and if the intending investors awake to the fact that a property should be

thoroughly prospected before contracting for a dredge, there is every reason to believe that a number of successful enterprises for small dredges will be developed in the future.

## Geological Field Work in Alaska

The delay in passing the appropriation bill has made it impossible for the United States Geological Survey to carry out all the field plans for Alaska that had been formulated for 1912, but the funds that became available by emergency appropriations made it possible to dispatch several of the smaller parties for a full season's work, and others started for Alaska as promptly as the appropriation permitted.

In southeastern Alaska the Survey proposes this year to study the gypsum and marble deposits. E. F. Burchard, who sailed from Seattle about the first of September, has been put in charge of this work and will visit the marble deposits near Wrangell and at the north end of Prince of Wales island.

Detailed surveys are being made of the west end of the Chitina copper belt, where important discoveries of ore have been made. A topographic survey of this field was begun on July 15 by D. C. Witherspoon and will be continued up to the close of the field season. The study of the geology and mineral resources of this district is being undertaken by F. H. Moffit, assisted by Theodore Chapin and J. B. Mertie, Jr. Mr. Chapin has been working with Mr. Witherspoon. Messrs. Moffit and Mertie sailed for Cordova on the first of September.

A detailed survey of the copper-bearing region adjacent to Galena and Landlocked bays is also being made this summer by R. H. Sargent and C. E. Giffen, who are engaged in making the topographic base map of this district, beginning work about the first of September. The geology of the same region is being studied by S. R. Capps and B. L. Johnson. G. C. Martin, who was detailed to make a study in the northern part of Kodiak island, reached Kodiak on the first of July. He spent six weeks in investigating the volcanic phenomena. On the completion of the investigation Mr. Martin undertook a preliminary examination of the mineral deposits of the western part of Kodiak island.

The discovery of gold in the Ruby Creek district and the large gold production from the Iditarod district made it imperative that the Geological Survey continue its investigation of this field, and H. M. Eakin was detailed for this purpose. He arrived at Ruby Creek about the middle of July and later extended his work southward to the Iditarod district.

For a number of years the Geological Survey has been investigating the water supply available for placer mining in the Yukon-Tanana region. This year R. W. Davenport was detailed to investigate the water resources of the Forty-mile district, and C. E. Ellsworth those of the Birch Creek and Fairbanks districts. This work was begun about the first of May and will be continued to the end of the open season. The important developments in lode mining in the Fairbanks district making it desirable to supplement the detailed survey already made of this field, Philip S. Smith was intrusted with this investigation. He arrived at Fairbanks about the first week in September, and it is hoped that he will be able to study most of the important discoveries of auriferous quartz in the district.

Through the courtesy of the United States Commissioner of the International Boundary Survey, a geologist was permitted to accompany the parties which are surveying the boundary north of the Porcupine river. A. G. Maddren was detailed for this purpose and accompanied the boundary party, which reached its field of operations about the first of June. It has just been announced that the survey through to the Arctic coast has been completed. Alfred H. Brooks, geologist in charge of the Alaska division of the United States Geological Survey, has been appointed a member of the Alaskan Railroad Commission, and is now en route to Alaska.

# Prospecting for Chromium Ore

By W. C. PHALEN

\*Chromite or chromic iron ore is the only important source of the element chromium. The metal chromium is known, however, as a minor constituent in many other minerals, among which may be mentioned certain varieties of spinel (picotite,  $(\text{MgFe})\text{O} \cdot (\text{AlCr})_2\text{O}_3$ ), garnet (uvarovite,  $3\text{CaO} \cdot (\text{AlCr})_2\text{O}_3 \cdot 3\text{SiO}_2$ ), muscovite (fuchsite, chrome glimmer), beryl (emerald,  $3\text{BeO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2 \cdot n\text{Cr}_2\text{O}_3$ ), chrome diopside, and clinohlore. In these minerals chromic oxide ( $\text{Cr}_2\text{O}_3$ ) is isomorphous with alumina ( $\text{Al}_2\text{O}_3$ ) or ferric oxide ( $\text{Fe}_2\text{O}_3$ ). Among the chromates, chrocoite ( $\text{PbO} \cdot \text{CrO}_3$ ) is the commonest, but other chromates are known, for example phenichrocoite ( $3\text{PbO} \cdot 2\text{CrO}_3$ ), vanquelinite ( $2(\text{PbCu})\text{O} \cdot \text{CrO}_3(\text{PbCu})\text{O} \cdot \text{P}_2\text{O}_5$ ), and chromates of certain of the metals of the caustic alkali and alkaline earth groups.

Chromite, the commercial source of chromium, is theoretically a mixture of chromic oxide and ferrous oxide with the symbol  $\text{FeO} \cdot \text{Cr}_2\text{O}_3$ . Theoretically it contains 68% of the former and 32% of the latter oxide. The two oxides may be present, however, in widely varying proportions. The percentage of chromic oxide may range from 40 to 60, or it may run as low as 10; the percentage of ferrous oxide may range from 10 to 50. Alumina and magnesia are usually present in the ore, sometimes in considerable amounts, the former replacing the chromic oxide and the magnesia replacing the ferrous oxide.

**Properties and Tests.**—The mineral chromite is iron-black to brownish black in color and has a brown streak. It has a metallic or sub-metallic lustre, but in some determinative mineralogies it is classified with minerals having both a non-metallic and a metallic lustre. It is infusible, or at most only the finest particles or sharp edges of the mineral are rounded before the blowpipe. It is not readily attracted by the magnet, if at all, but a little of the mineral when finely powdered and mixed with an equal amount of carbonate of soda and intensely heated on charcoal forms a mass which is attracted by the magnet. The mineral imparts a green color to the borax or salt of phosphorus beads. The cleavage or fracture of the mineral is uneven. Its hardness is 5.5; its specific gravity 4.2. It crystallizes in the isometric system. A knowledge of the above properties should make the determination of the mineral a matter of little difficulty either in the field or in the laboratory, to the prospector supplied with a simple blowpipe outfit.

## OCCURRENCE

The mineral chromite occurs disseminated in basic eruptive rocks of the peridotite, amphibolite, and pyroxenite groups, and particularly in the serpentine and talcose products resulting from their alteration. Since this is the rule, and practically without exception, it is in these classes of rocks that effort should be expended in searching for new occurrences of the mineral. Chromite is widely distributed through areas of serpentine and associated basic rocks in different parts of the United States. Serpentine areas in the United States have been found in a few localities in the old metamorphic rocks which stretch from New England to Georgia; at various points in the Rocky Mountain region; throughout the extent of the Sierra Nevada and Coast ranges in California, and at a few places in the Cascade mountains. The mineral occurs widely disseminated through many of these areas, but it is concentrated into workable quantities only locally. In the United States deposits of chromic iron ore are found in Massachusetts, Pennsylvania, Maryland, North Carolina, Wyoming, California, and in the black sands of the Pacific Coast. In the last few years chromite has been produced mainly in New Caledonia, Rhodesia, Asia Minor, Russia,

Greece, Canada, India, Japan, and other countries.

**Massachusetts.**—In Massachusetts chromite occurs disseminated in the serpentine phases of amphibolite in Hampshire and Hampden counties near the Berkshire county line. No orebodies of commercial importance have as yet been found.

**Pennsylvania and Maryland.**—In southern Pennsylvania and northern Maryland numerous areas or bands of serpentine are found in a belt running northeast and southwest and extending from Delaware county, Pennsylvania, through Chester and Lancaster counties in the same state, and through Cecil, Harford, and Baltimore counties, Maryland. This serpentine contains considerable chromite disseminated and in the form of lenticular bodies. As the serpentine disintegrates, the chromic iron ore collects as sand and gravel along the streams. These stream deposits and the solid ore lenses have yielded considerable ore where mined in southeastern Lancaster county, Pennsylvania, near the state line in Harford county, Maryland, and in Baltimore county, Maryland.

**North Carolina.**—In western North Carolina chromite occurs associated with dunite (simple olivine rock) in Watauga, Yancey, Madison, Buncombe, and Jackson counties. The chromite generally occurs as small grains disseminated through the dunite, but a few important deposits have been found. The mineral is found as small disseminated grains and as balls and nodules of various sizes, only the latter type being of importance as ore. One of the larger deposits north of Burnsville, Yancey county, was 3 ft. in its greatest diameter, while another, southwest of the town, contained several tons of ore.

**Wyoming.**—A deposit of chromite is known in Deer Creek canyon, Converse county, Wyoming, about 15 miles southwest of Glenrock. The orebody is lens-shaped and occurs in serpentine in a box canyon on the northern slope of the Laramie hills.

**California.**—In California chromite is now known to occur in a large number of counties, and in 1911 it was reported as having been mined in three, namely, Shasta, Siskiyou, and Tehama counties. An occurrence of chromite in Shasta county is situated in the western part of the county on Shotgun creek, but the serpentine in which it occurs extends as far south as Slate creek. At the forks of Shotgun creek, about a mile from the Southern Pacific railway, a series of lenticular chromite bodies occur in a somewhat indefinite shear zone which is vertical and courses S. 40° W. through the serpentine. Five bodies connected with more or less distinct vein-like leaders have been mined. The ore generally separates easily from the serpentine, but in places it is firmly 'frozen' to it. Other parallel zones have been found in the same region. An incomplete analysis of the material gave 43.87% chromic oxide.<sup>1</sup>

A belt of serpentine having an approximately north-south strike runs through the southwestern part of Tehama county and the northwestern part of Glenn county. The belt is on the lower eastern slope of the Coast range, called Yolla Bolly mountains. Chromite float is found in this serpentine in a number of places. Mining operations have been conducted on the north fork of Elder creek in Tehama county, and at the Black Diamond mine near Newville, Glenn county. The ore shipped from the Tehama county locality was on the basis of 47% chromic oxide as a minimum. The Black Diamond mine has also yielded considerable ore.

In Siskiyou county considerable chromite float in relatively small pieces has been found in serpentine near the top of the Forest mountains. Chromite float has also been reported from 10 miles southwest of Gazelle in the same county.

Many years ago chromite ore was shipped from San Luis Obispo county in considerable amount. The chromite ore occurs in irregular pockets and stringers in serpentine which is deeply disintegrated in most places. The ore was obtained from this disintegrated material. Owing to

\*Published with the permission of the Director of the U. S. Geological Survey.

<sup>1</sup>Diller, J. S. Redding folio No. 138, Geologic Atlas, U. S. Geol. Survey, 1906.

the way in which the ore occurred, mining was mostly surface work and many pits were scattered over the area. The principal mines were eight or nine miles north of the town of San Luis Obispo in the serpentine hills of the Santa Lucia mountains. Other mines were west and southwest of San Luis Obispo in the Los Osos mountains. In the northwestern part of the county on the western slope of Pine mountain chromite occurs under similar conditions. The cost of mining the ore found in San Luis Obispo county was somewhat high owing to its occurrence in relatively small pockets disseminated through the serpentine.

In addition to the occurrences mentioned above, chromite is known in other counties in California, among which are Alameda, Amador, Butte, Calaveras, Del Norte, Eldorado, Fresno, Mendocino, Napa, Placer, Plumas, San Benito, Santa Clara, Sierra, Sonoma, Trinity, and Tuolumne.

*Rhodesia.*—Rhodesia and New Caledonia are the two countries producing most of the chromic iron ore at the present time, and are also the countries in which development seems most promising. The Rhodesian deposits may be cheaply mined and shipped to seaport at a low rate, so that their production has increased rapidly, notwithstanding their remoteness from market and the fact that the production of chromic iron ore has been somewhat irregular during recent years. The important deposit of chromic iron ore occurring at Selukwe, Rhodesia, is a huge segregated mass associated with serpentine. It is easily mined, the supply is large, the cost of mining is low, and the deposit is in close proximity to the railway. Hence the production has increased rapidly, notwithstanding the remoteness of the deposits from market. Chromite is known in other parts of southern Rhodesia—for example, at Victoria, Makwiro, and Lomagundi—and it is not unlikely that these deposits contain large bodies of ore. The chromic oxide content of these ores varies and is sometimes low, as at Makwiro. The deposits appear to be connected with the great intrusion of pierite which runs north and south through southern Rhodesia from the Zambesi river almost to the Limpopo, and is marginally altered to serpentine in several places.

*New Caledonia.*—A large part of the world's present production of chromic iron ore comes from New Caledonia, a French possession, east of Australia. The mineral was discovered there in the early seventies. In the deposits in the southern part of the island the ore occurs: (1) as rich, soft, and easily broken masses in a ferruginous clay, and (2) in the forms of veins and masses in serpentine. The more friable ore, being the more easily separated from the country rock, is mainly sought after. The only chromic iron ore mine on the island which is worked below the surface, is the Lucky Hit in the group of mines to the south of Noumea. This ore as mined contains from 30 to 40% chromic oxide, and is concentrated mechanically to raise it to marketable quality. The largest deposits are in the northern part of the island around the Tiebaghi mine, the yield from which is approximately 4000 tons of ore per month, containing up to 67% chromic oxide.

#### USES

The uses of chromium may be classified as chemical and metallurgical. Under the former is included its use in the manufacture of pigments, dyes, mordants, and in special tanning processes; under the latter its application as an ingredient in bricks and furnace linings and in the manufacture of special steel alloys. The element received its name from its tendency to form colored compounds. Among the chromium pigments are chrome green, Guignet's green, chrome yellow, chrome orange, and chrome red. Three chromium colors are used as dyes, namely, chrome yellow, chrome orange, and chrome green. Chromium salts, including chromates and bichromates, are used in the dyeing and printing of cotton, linen, and wool. They act as oxidizing agents and are reduced to chromic oxide, which is fixed on the fibre. The goods are then ready to hold the desired dye. Tanning with certain metallic salts, among which those of chromium are used, has become important

for certain light leathers. Leather tanned with chromium salts is tough and resistant to moisture.

The mineral chromite itself is used for furnace linings in the form of brick made of crude chromite and coal-tar, which are held in place by tar mortar. Sometimes mixtures of chromite and other materials are used, and the chromite may be used in the crude form alone. Chromite seems to have several advantages for use in furnaces used for smelting lead, copper, antimony, and other metals, the slag from which rapidly attacks acid linings. Much, if not all, of the California chromite is used in the manufacture of furnace linings. The price of chrome bricks f.o.b. Pittsburgh, Pennsylvania, was \$175 per thousand in 1911. Chromic iron ore is used in making ferro-chromium employed in the manufacture of special steels, either alone or in combination with other steel-hardening metals like tungsten, manganese, and nickel.

#### DEMAND

The magnitude of the demand for chromite may best be ascertained from the domestic production—that is, the output of the domestic mines actually sold—and the importations. The production in 1911 in the United States came entirely from California and amounted to only 120 long tons, valued at \$1629, or \$13.57½ per long ton. The importations of ore were 37,540 long tons, valued at \$407,958. There was imported besides, a small quantity of chromate and bichromate of potash, and chromic acid. Imported chromic iron ore from New Caledonia, carrying 50% chromic oxide, was quoted in New York during 1911 at from \$14 to \$16 per ton, this price being for earload lots and exclusive of cost of transportation. The ore is usually purchased on a basis of 50% chromic oxide, but when the percentage of the oxide exceeds this figure, the value of the ore rises in proportion.

## Gold in the La Sal Mountains

By J. M. HILL

\*The La Sal mountains are in the Colorado plateau region, which is characterized by long mesas cut by canyons 2000 to 2500 ft. deep, with steep cliffs 500 to 600 ft. high. Above this relatively level plateau, which has a general elevation of 8000 ft., the northern group of the mountains rises abruptly at Mount Waas to a height of 12,586 feet.

Two classes of mineral deposits are worked in the vicinity of Basin and Mesa. In the mountains there are several quartz-mining prospects and at least one locality where placer gold has been recovered. The quartz mines have made practically no production, and it is probable that \$5000 would cover the entire output from both quartz and placer mining in the region.

The quartz prospects in the northern La Sal mountains are few in number and the value of the ore is low, even at the surface, where many gold-bearing deposits in other districts are enriched. The veins, so far as they can be seen, are small and contain much barren quartz. The high charges for transportation to the railroad at Cisco, ranging from \$12 to \$15 for outbound and \$25 per ton for inbound freight, are an additional handicap.

The placers of Wilson Mesa are apparently of small extent. They contain only a small quantity of gravel, and all the gold in it cannot be saved by sluicing, because some of it is carried in boulders, which require some sort of crushing. They include so much material that surely carries nothing of value that it would hardly seem advisable to install expensive crushing and amalgamating machinery unless it were found practical to sort the ore from the waste by hand. Besides these unfavorable conditions, only a very small and uncertain supply of water is available for placer operations. The placers contain, however, some free gold that might be procured at a profit if the deposits are worked in a small way.

\*From Bulletin 530-M, U. S. Geol. Survey.

# Production and Allied Statistics, California Oilfields

By J. H. G. WOLF

Statistics present but dry facts, but when studied for their significance they exhibit the trend of an industry in an unmistakable way. The second of the accompanying tables shows the world's production of crude petroleum in the decade from 1900 to 1910, showing the relation of the growth of the industry in California to that of the United States. The first gives the statistics of California production from the time immediately preceding the bringing in of the Lakeview well (and the attending flowing wells of large capacity in the Sunset-Midway field of the West Side of Kern county) to and including July 1912.

ply fuel on the Atlantic seaboard as California is now supplying the Pacific.

It is fortunate that these discoveries have come at a time when Russia's supply is declining heavily and all the known fields of the United States are apparently either at the maximum of their productive possibilities, or are on the decline. It comes also at a 'psychological moment'—the opening of the Panama canal, when the world's trade routes are destined to be re-routed, and the Pacific will become the theatre of the struggles for commercial supremacy; for trade rules the world.

Total number of 'Pumping Wells' does not include the 412 wells of the Los Angeles City field and the 125 wells of the Summerland field, the combined production of which wells does not exceed 1200 bbl. per day; their yield, however, is included in the figures of the state's yield each month.

In the figures for 'Stocks' there was an adjustment for losses in storage, seepage, Lakeview well losses, etc., in October, 1911.

Referring to (2), while the world's production doubled in the decade from 1900 to 1910, and that of the United States tripled, that of Russia, which up to this period had led all countries, declined from 85,000,000 bbl. to 70,000,000 bbl. per year. In 1901 the United States produced 41.6% of the world's supply; in 1910, 60.8%. In 1901 California produced 5.2% of the world's yield, and 12.6% of that of the United States, while in 1910 the figures had leaped to 23 and 36%, respectively.

The significance of these figures is much enhanced by the fact that the discoveries of the past few years of new fields and of extensions of old fields, in the southern San Joaquin valley, make it practically certain that California can and will supply all the petroleum for which there is a market for many decades to come. So vast an area has been added to the previously known deposits, and so profusely have the known fields produced when once opened, that it is with difficulty any approximate estimate can be given of the state's probable future annual yield. Mexico is the only country where there is much promise of new fields of magnitude, aside from California. The Mexican fields are contiguous to the gulf coast and promise to sup-

Referring to (1), while stocks have increased in the past two years some 15,000,000 bbl., there has been no appreciable gain in the daily yield of California since April 1910, or the month the Lakeview well first poured forth its enormous yield. (The well was brought in March 15, 1910.) There has been an apparent increase of daily shipments to the trade (consumption) of 50,000 bbl. between July 1910 and July 1912. This gain in delivery to the trade has been a healthy one, but it has been at the expense of the producer; prices dropped from an average at the well of 50c. per bbl. the day the Lakeview was brought in, to 30c. On the other hand, the consumer who was paying 90c. per barrel delivered on San Francisco bay early in 1910 has since obtained his supply at as low a figure as 65c. It is reputed that quotations on the bay now range to 80 cents.

It should be remembered that about 70% of the California yield is consumed as fuel oil, and that 40% of the remaining 30% that is refined, possibly 40% comes back into the fuel market in the shape of residuum, so the oil consumed as fuel is somewhat greater than the 140,000 bbl. indicated daily consumption. The price of 30 to 35c. to

producers is upon probably 70% of the state's yield. Price varies according to specific gravity; the high-gravity refining oils, the equivalents of the Pennsylvania crude, bring as much or more at the wells than the same grade in the Eastern fields, but the quantity available is small. The recently discovered Lost Hills and the Belridge fields (the latter an extension of the McKittrick field) are yielding a fine supply of over 30°B., and this, with the extension of

When these figures are compared with the yield of the Appalachian field, 1.73 bbl.; Lima-Indiana, 2.74 bbl.; Illinois, 8.37 bbl.; Mid-Continent, 5.27 bbl.; and Gulf, 14.08 bbl., the significance of the producing business in the California fields can be more easily grasped. It is probable that the high yield per well will continue for some years, due to the influence of the production from newly opened ground.

Work Along the Mother Lode

By C. W. MORSE

Following are some notes made on a hurried trip along the Mother Lode.

Good management has kept the total working costs of the properties visited from \$2.75 to \$3.75 per ton, while better ventilation, the use of stoping drills, and a bonus system in some contracts have helped to keep down costs. It was a surprise to find mines as old and with ground as heavy as the mines of the Mother Lode with only one opening to the surface. A property where five times as many men are employed on timbering as on ore, and where timber costs 50 cents per ton, is interesting to those not familiar with heavy ground.

At the South Jackson new shaft the Ingersoll-Rand hand drill 'B.C. 26' is in use with satisfactory results in the slate, some of which is hard. The drill is rotated by hand; uses hollow steel rose bits. The holes are put down at any angle desired, to a depth as great as 8 ft., though 6 ft. is the average depth. The best record for a round in the softer slate was 5 hours for 24 holes and 6 plugs. In the harder slate 9 hours has been required

ARGONAUT 40-STAMP MILL.

for a round. The shaft is 3-compartment, each being 4 by 5 ft.; 12 by 12-in. timbers are used with 8 by 12-in. spreaders. The sinking record for last month was 112 ft. It will be interesting to learn how these drills work in hard rock. The same company makes a similar drill with a self-rotating chuck, which should be an advantage.

In the same shaft delayed-action fuses are giving excellent results, and their use should be compelled by law for all shaft work. They would be valuable in any close place in the mine. They have very few misfires. A frequent cause of misfires in fuses is poorly insulated lead wires or wires on which the insulation has been damaged by tamping or rough handling. The water in the average drill-hole contains enough mineral salts to make it a fair conductor, so enough current may pass between the two lead wires to prevent the platinum bridge being heated to the ignition point of the fulminate, thus allowing some of the fuses to fail while others explode. I found this to be the cause of misfires in a salt mine in central Kansas, where damp salt was used for tamping. The same weakness was found to be the cause of annoying misfires in the Panama canal work. At the South Jackson the fuses are connected in parallel to two pieces of telephone wire which are in turn connected to the cable from the soil on the surface. The blaster carries the key to the switch-box on the light circuit, and when all are out of the shaft he connects the cable and throws in the switch.

Around Jackson there have been several cases of hookworm among the miners, and in Angels one case was heard

the practice of extracting the gasoline from the natural gas which has heretofore gone to waste, has eased the local demand for refinable products materially.

In July 1910 there were 3695 actively producing wells, yielding 222,644 bbl. per day, or 60 bbl. net to the market each day from each well; in July 1912 the yield was 43 bbl. per well per day, or about what it was in 1909, before the Lakeview and wells of its class had entered the lists.

of. The mines have probably been infected by the European laborers employed. The miners are peculiarly susceptible to malaria. The physicians disagree as to the extent of fibrosis. One thought that few of the miners escaped; others thought that not many were affected. As the miners do not apply for life insurance, they do not come under as close examination as those working at other trades. Chronic bronchitis is not prevalent. The stope drills are the cause of much irritating dust. At one mine they tried using the spray attachment, but, as usual, the miners objected to the use of any new device and preferred to 'eat dust.'

## Precipitation of Copper From Mine Water at Butte

The large amount of copper annually recovered from copper-bearing water at Butte is not generally realized. In 1910, a total of 4,558,850 lb. of copper was recovered by precipitation on scrap iron. In 1911 the water pumped from the Leonard shaft yielded 600,000 lb., while the water from the High Ore shaft yielded about the same quantity. Not all of this large quantity is produced from the mine water, however, as the leaching of old tailing, slag, and waste heaps by lessees adds very materially to the output. The recovery of copper from the mine water is of the greatest interest, however, since the quantity thus recovered is sufficient to pay the cost of pumping and yield a small profit. Handling the underground water, instead of being a heavy burden on the cost of working, is at Butte a small source of profit.

It is difficult to give exact data regarding the precipitation of the copper, since the character of the mine water varies a good deal, both according to the season of the year and according to the part of the workings from which it is derived. At one time much water was used in the Leonard mine in an attempt to extinguish an underground fire. The copper-content of the water obtained from this part of the workings was considerably above the average, but for some unknown reason this water formed a curious precipitate upon the iron, resembling fungus growths, which greatly interfered with its efficiency as a precipitant. Similar growths are also found within the mine, often on the mine timbers, and have given rise to much discussion as to whether they are vegetable or mineral growths. The following is an analysis of the water from the Leonard mine:

	Per cent.
Copper .....	0.0122
Iron, suspended .....	0.0127
Iron, solution .....	0.0067
Arsenic .....	0.00026
Antimony .....	0.000088
Free H <sub>2</sub> SO <sub>4</sub> .....	0.0139

The water is handled by pumps with bronze working-parts, and pumped through a column-pipe lined with wood or lead. On the surface the water is passed through a series of boxes and trays. At first the water flows at a rapid rate over large pieces of scrap iron and steel, and the precipitate collected at this point is high-grade, containing as much as 80% copper. Farther down smaller pieces of iron are used and a slower rate of flow. The final precipitation is accomplished on small scraps, chiefly old tin cans spread in layers on trays, the water dripping slowly from one layer to another. In this way practically complete precipitation is secured, analysis showing that with mine water which carries 0.03893% copper, the final effluent carries only 0.00036% copper, corresponding to an extraction of 99.1% of the copper in the water. The low copper content of the escaping water has been compared with that of the effluent solution at Rio Tinto, but it must be remembered that at Rio Tinto the copper-bearing solution carries 0.4% copper and the 0.002% copper content of the effluent solution corresponds to an extraction of 99.5%. Another analysis of Butte mine water shows an original content of 0.0099% copper, the water entering at 73°F.

and escaping at 65°F. with a copper content of 0.0008%, corresponding to a 92% extraction. The average copper content of the precipitate is 45%. A curious fact worth noting is that the arsenic content of the mine water at Butte is extremely low (less than 0.0003%), although about one-quarter of the copper present in the ore is in the mineral enargite, which contains nearly 20% arsenic. At Rio Tinto, on the other hand, the amount of arsenic present in the ore is small, yet according to C. H. Jones\* the copper-bearing solution contains 0.03% arsenic. This and the fact that pig iron instead of scrap steel is used for precipitation of the copper has a marked effect upon the process there employed, for both the arsenic and phosphorus come down in the final stages of the process, and form most undesirable constituents of the copper precipitate. It is not feasible, therefore, to reduce the copper content of the effluent solution so low as at Butte. At Rio Tinto, 140 lb. of pig iron is required to precipitate 100 lb. of copper, and at Butte about 150 lb. of scrap iron and steel is required.

## Work of the Aguacate Mines

By P. G. SPILSBURY

The following extract from the financial statement of the Aguacate Mines for the six months January 1 to June 30, 1912, may be of interest.

Total operating costs:

Administration .....	\$0.47
General expense .....	0.46
Mining .....	1.62
Tramming .....	0.52
Milling .....	1.24
Marketing bullion .....	0.07

Total .....	\$4.38
Credits from land rentals and store .....	0.17

Net cost .....

From the mine 6713 wet tons of ore was extracted, and 5863 dry tons milled, of an average assay value of \$12.15. The cost of constructing the experimental cyaniding plant, completing the mill, erecting a steam power-plant for the dry season, installing mine-bins and sorting-floor, and other mine improvements, and erecting necessary houses for the staff, all considered as permanent betterments, amounted to \$2.49 per ton. During this period wood fuel was used for power.

General items of interest follow: All power at present is being furnished by the hydro-electric plant. For the next dry season the steam-plant will be moved to the site of the present electric plant, and the engines connected so as to run on the same shaft with the turbine. This plant will develop a minimum of 100 hp. It is expected that electric power sufficient for all needs will be available at the mines before July 1913. Results in the preliminary cyanide plant have been such that a 100-ton unit will be added at once, and it is hoped to have it in operation by January 1913. It is planned to place a trommel before the stamps and to send fine ore direct to a 5-ft. Huntington mill, only coarse ore going to the stamps, thus increasing the efficiency of the crushing plant.

IMPORTS of gold and silver into Japan for the first eight months of the current year have been ¥10,981,000, and exports ¥16,013,000. The Nippon Ayenko Kabushiki Kaisha (Japan Zinc Ore Co.), which was recently formed, has started to work its mine at Kakeorizawa, Echigo province. The company has also six mining properties in the same district, all being in working order, the daily output of ore being 15 to 20 tons, the product containing 40 to 55% zinc. By November the output will be increased to 1000 tons per month. The company invites anybody purchasing ores to inspect its properties.

## Placing Shaft-Sets

By TOM McCORMAC

When things go right a shaft-set can be swung, blocked, and lagged in a surprisingly short space of time. The problem is to systematize the work into some such definite routine as to insure 'things' going 'right.' This is sometimes a little harder to do than it would appear, as many miners, some experienced in but one piece of shaft work, and that one probably a sad example, consider it a reflection upon their ability as shaftmen to be shown anything so simple as a detail in putting in a set of timber. These men are hard to interest in any attempt at system, as they think it entirely unnecessary. Yet these same miners, putting in shaft timber, will bring up a varied assortment of hard-luck stories explaining just why it took so long to place the set; entirely oblivious to the fact that each preceding set seemed to necessitate stories of the same uninteresting sort. It is far more satisfactory to insist upon a system at the start, even though assured by experts that many details are unnecessary.

The first essential to fast work is to know that there is sufficient room in which to swing the set; and it is a never-ending source of surprise to me to see how poor the judgment of men in this matter is. In spite of the fact that an attempt to swing a set in a shaft, where there is not sufficient room, is not compatible with good sense, still it is very frequently tried. A measuring stick and a short plumb line will settle this point absolutely, and the time required is not worth considering.

Next is a suitable platform from which to work. If the rock be so soft that the timbers can be carried close to the bottom of the shaft, no platform will be required; the timbers can be put in from the rock pile. If the rock is harder, a platform is necessary, and is sometimes made by placing two stulls in the shaft at such a distance below the last set as to give convenient working room. On top of the stulls are placed the platform planks. A much better plan is to provide four stirrups of iron, 8 or 9 ft. long, that can be hooked on the last set and, in a loop at the bottom, support a 4 by 6 which corresponds to the stull. Across these timbers, one at each end of the shaft, can be placed the platform of a few planks. If a blasting set is used, it can be dropped on the cross pieces, and used as a staging instead of the planks. With the platform in place, sufficient ground removed to accommodate the set, and the hanging rods in the proper holes in the last set, the timbers can be lowered. These should be lowered with a clevis. The timber hitch, even when guarded with a half-hitch is, in my opinion, absolutely dangerous and should not be allowed. The most dangerous feature of this hitch is the fact that in the great majority of cases it will hold; which breeds a carelessness that might easily be attended with fatal results. The clevis can be made by any blacksmith in a few minutes out of any flat piece of iron. It is shaped like the letter 'U,' with holes in each end through which a bolt is passed.

In lowering the timbers the topman can easily send down the plates in a regular order; for instance, let him invariably send down the north wall plate first, followed by the south wall plate, and so on. He should also see that the right end goes down first, which will prevent any necessity for turning the timber in the shaft. When the wall plate is lowered the clevis is removed, the two hanging rods are put in, and, if the timber is not too heavy, it is hooked into place. If heavy timber is being used it can be guided to place while it is hoisted from the surface.

When the plates are put together it is sometimes the practice to drive a big nail through the 'horn' of the end plate into the wall plate, to keep the two pieces together. The 'horn' is already the weakest part of the plates, and the advantage gained by holding the members of the set together is, in my opinion, much more than offset by the disadvantage of splitting the 'horn,' which frequently takes

place. If something of the kind is desired, dowel pins can be used; these have given good results, although I have never happened to use them. In my next work, however, I intend boring a very small hole through the tenons of the plates and pinning them together in the shaft with pins made of heavy wire nails, cut to the proper length.

With the plates in position and the posts in their places the hanging rods are tightened up solidly. Washers should, of course, correspond with the rods used, although I have seen a very heavy hanging rod accompanied by a little cut washer but slightly larger than the nut. In this case the appearance of solidity given to the shaft by the use of heavy iron was false.

The four lines are next dropped; there are men who need but three, and, I suppose, still others who can manage with but one, nevertheless, four lines make easier, quicker, and more accurate work and take up but an extra moment in the hanging. It is best to plumb from the same set for at least 50 ft., and as much farther as it is possible, without losing time caused by the swinging of a long line.

With the lines in place and fairly still, the set should be swung approximately to its place and held there by nailing short pieces of board on top of the wall plate and against the rock. Two on each wall plate and one on each end plate will hold the set solidly and nearly in its right place. These little pieces do not interfere with the blocking, since when the blocking is in place they can be knocked off, if in the way. The measurements for the proper length of blocks will fit exactly.

The topman can pick out the blocks according to the measurements sent up, perhaps being required to saw one or two of unusual length. Whether the pressure on a block should come against the grain of the wood or across the grain is a question that I would like to see discussed. If a block can be put into a shaft parallel to the posts, in this case the pressure coming across the grain, it would save some time in blocking a set. It is very easy to split this block and by driving wedges in the block itself the set can be made very solid. It is my own opinion, however, that this is poor work; that a block put in a dry shaft, after this fashion, will in the course of time fall out on account of the wood shrinking. Blocking should proceed slowly. Rush work loses time. In a large crew two men should do nothing but watch the lines and prevent any block from being tightened up too rapidly. If a block is tightened too much, the opposite block will not be able to force the set back to place, and a lot of time will be lost loosening the first block. Deliberate work pays at this time. Make each and every blow of the hammers accomplish some definite purpose. If the wedges in a shaft are placed with the sawn side against the rock they will not split so quickly.

All the blocking should be placed out of the way of the lagging; although there are some corners that would require too much moiling to permit this, and if this is done the lagging can be quickly put in place. If no attention be paid to this there will be sixteen corners to be cut in fitting the lagging to the posts. This is time lost.

If a definite routine be followed it will only be a matter of placing a few sets before a very high rate of speed can be attained, and this with no loss in accuracy. There is nothing mysterious about the placing of shaft timber; any intelligent miner with a desire to learn and the proper teaching, can learn all the rudiments in a single day. Speed, of course, is a function of experience and cannot be obtained in a day, but neither does it require any such time as a year.

CASSITERITE has been discovered at two or three points in Rhodesia, but as yet the exploitation of these deposits has not proved profitable. It is already reported that an apparently large and important deposit has been located at the Arcturus district of Mashonaland, and that a good deal of Johannesburg capital is to be devoted to the making of a thorough investigation of the mineralized area in question.

## American Institute of Mining Engineers and Its Affairs

The following analysis of the comparative statement of receipts and disbursements for the six years 1906 to 1911, inclusive, given on pages 26, 27, and 28 of the report of the Committee of Five, has been prepared by Charles Kirchhoff, to show what the position, financially, of the Institute is now, and will be for the next few years, assuming that it continues at the same rate of normal receipts and expenditures. The net loss shown by the accountant's statement for the period under review, taking credit for interest received, amounted to \$12,696.72. During that period the Institute paid in rents and assessments:

### RENT AND ENGINEERING BUILDING ASSESSMENTS

1906	Rent 99 John street.....	\$ 2,500
1907	Assessment for operating building.....	10,250
1908	" " " " .....	6,700
1909	" " " " .....	6,000
1910	" " " " .....	4,500
1911	" " " " .....	4,500
Total .....		\$34,450

At the present rate of assessment of \$4500 per year (under which the United Engineering Society is accumulating a fair surplus), the outlays would have been for the same period of six years \$27,000, so that the next period of six years should show a saving in that respect of \$7450.

The total payments for the interest on the Institute's share of the Engineering building land mortgage for the six years aggregated \$30,462.99, as follows:

### PAYMENTS FOR INTEREST ON MORTGAGE

1906 .....	\$ 9,133.33	1910 .....	\$ 3,520.00
1907 .....	5,200.00	1911 .....	3,133.66
1908 .....	5,200.00		
1909 .....	4,276.00	Total .....	\$30,462.99

At the present time the Institute is paying interest on \$68,000 net, or \$2720 per year. Had the generous gifts of friends of the Institute to the land fund been received at the beginning of the period under review, instead of flowing in at a later date, then there would have been a saving in interest of \$14,142.99, namely, \$30,462.99 less \$16,320 (six years interest at the present rate). In order to fairly judge of the ability of the Institute to meet its costs in the future, based on the normal expenditures of the last six years, there must be eliminated the two sums mentioned: \$7450 representing extraordinary building assessments, and \$14,142.99 in interest payments, which it need no longer face. The two sums amount to \$21,592.99, so that deducting abnormal outlays now no longer a possible burden, the apparent net loss of \$12,696.72 is transformed, so far as the normal conditions of receipts and expenditures are concerned, into a surplus of \$8896.27. This surplus would have enabled the Institute to place to capital account the greater part of the sums received for life memberships, which aggregated \$10,500, somewhat irregularly distributed over the six years under review. Under present conditions the Institute is not facing an annual deficit in its operating expenses. With an income based on dues of \$10 annually, and normal receipts and expenditures on the scale of those of the period of 1906 to 1911, both inclusive, the Institute will be able not alone to carry on its work as well as heretofore—maintain the standard and volume of its publications, pay the regular annual assessment of \$4500 for its share in the cost of operating the United Engineering building, pay the interest on the present mortgage debt—but to place to capital account hereafter the receipts from life memberships.

In 1907 the Institute had pledged itself under the founders agreement to pay \$180,000 as its share of the land mortgage. That amount has now been reduced to \$68,000, and no payment will be due on this balance of \$68,000 until 1915. It is believed that through revenue received

from the natural increase of membership as well as through further contributions to the land fund from friends of the Institute, this debt will be fully met. It should be appreciated that such a settlement will give the Institute an unencumbered one-third interest in a property worth \$1,659,320, in which our equity today is not less than \$480,000.

The following two circular letters will be of interest to members of the Institute:

At the last annual meeting of the Institute, in February 1912, a Committee of Five was appointed to investigate all the affairs and operations of the Institute, to see whether an increase in the dues could be avoided, and to report to the Board of Directors, making such suggestions as they might deem best for the welfare of the Institute. This committee made an exhaustive examination, and its report has been distributed to our members. As was shown in the report, the management of the Institute has been striving for some years to reduce expenses and increase its efficiency. The suggestions of the committee, even those that seem to be inadvisable or impracticable, are being carefully considered by competent committees of Board and Council. There are certain matters which will come before the adjourned business meeting on October 7, 1912, to which careful, dispassionate consideration should be given.

1. The report of the Committee of Five should be accepted, and, with its accompanying papers, correspondence, accounts, reports, etc., be filed in the archives of the Institute, the committee be discharged with thanks, and the Institute be left to the management of its duly constituted authorities, the Council and the Board of Directors.

2. On the question of increasing the dues, even temporarily, the report of the Committee of Five does not justify a final conclusion. We believe that our fellow-members would neither wish to have the dues unnecessarily increased nor, on the other hand, see the means of the Institute restricted or its work crippled. We have before us the important matter of paying off the balance of the land debt, and the plans of judiciously aiding the local sections and the professional divisions, on which we count so much to help the growth and widen the beneficial influence of the Institute. We urge the postponement of action on this suggestion, and also on the other constitutional amendments suggested last year, until the next annual meeting in February 1913, when we shall have further light from this year's budget. By that time, present uncertainties will be cleared up as to routine finances, voluntary contributions to the land fund, and the amount of new resources coming from the somewhat rapid increase in membership.

3. We believe that it is not necessary, preliminary to progress and to a solution of the new problems, to attempt to throw discredit upon the past management of the Institute, or to belittle the debt of gratitude which the Institute owes to Dr. R. W. Raymond, who served it for many years with distinction and rare devotion and self-sacrifice, and who more than any other man brought it to its high place among the technical societies of the world.

4. We believe that the membership at large should be given an opportunity to express its endorsement of the action of the Board of Directors and of the Council when they recognized Dr. Raymond's lifelong services and devotion by unanimously electing him an honorary member, and to act affirmatively on the recommendation of the Committee of Five to make possible the conferring upon Dr. Raymond of the title of Secretary Emeritus.

5. We believe that the membership at large should be given an opportunity thus to approve and ratify the action of the Board of Directors when they took steps to secure for the future his aid in that part of the editorial work of the Institute which he is so eminently qualified to perform.

6. We believe that the Institute should extend to Dr. Raymond, now that he has retired from the active direction of its affairs, suitable facilities for carrying out such work, with a proper annual stipend along the general lines as arranged by the Board at the time of his retirement from active participation in the affairs of the Institute 18 months ago.

The second letter is as follows:

In February last we addressed a circular to the members of the Institute asking for proxies to postpone action on the proposed amendments to the constitution and to have a committee appointed to study and report on the affairs of the Institute so that the members might be able to vote intelligently on these propositions. The responses were most satisfactory, over a thousand proxies having been received.

The committee was appointed and was purposely composed of men of very divergent views. Three were among the signers of the circular and two had been members of the Board of Directors of the Institute for many years. With a committee so constituted the report was necessarily a compromise and did not fully express the views of any one of its members. We hope, however, that it was full and explicit enough to serve the purpose for which the committee was appointed. The proxies received were also used at that meeting in furthering the election of George C. Stone, Charles F. Rand, and E. B. Kirby to the directorate of the Institute. They were not voted at all in the matter of the secretaryship of the Institute. This was intended to indicate a suspension of judgment. Mr. Kirby was elected to the Board in order to give the very large Western membership at least some representation in that body.

At the adjourned annual meeting to be held October 7 some decision should be reached in regard to the amendments proposed last year, and probably action will be required on other matters referred to in the report of the Committee of Five. We therefore ask for new proxies to enable us to act on these questions, as we do not feel that the old ones, although of sufficient general scope, should be used as they were really granted for a definite purpose that has been accomplished. We agree with the opinion expressed in the report of the Committee of Five, that the present financial deficit may be met by the reductions which are possible in the expenditures of the Institute. It will, however, take some time to secure this, and it is necessary to provide now for the possibility that the reduction may not be sufficient for the purpose. Therefore we propose to offer an amendment to the constitution in the following sense: giving the Board of Directors the right to increase the annual dues not to exceed \$5 a year, for such length of time as may be necessary to pay off the land fund; the increase to be used solely for that purpose and the dues to automatically recede to the present basis of \$10 per year as soon as the object is attained.

It is our opinion: That all of the amendments to the constitution proposed last year should be rejected. That the meeting should be again adjourned to the date of

the Cleveland meeting of the Institute. This is to allow of full discussion of any matters appertaining to amendments of constitution and by-laws brought up October 7 before final action at the next annual meeting in February 1913. The present constitution precludes action on any amendments which have not been proposed in their final contents at a previous annual meeting.

GEORGE C. STONE,	JOHN H. ALLEN,
J. PARKE CHANNING,	J. A. VAN MATER,
ROBERT PEELE,	EDMUND B. KIRBY,
RICHARD H. VAIL,	H. M. CHANCE,
C. R. CORNING,	F. L. GARRISON.

A meeting of the San Francisco members of the American Institute of Mining Engineers was held on September 21. Members present were: E. H. Benjamin, S. B. Christy, Frank Dennis, H. W. DuBois, J. B. Farish, A. A. Hanks, E. A. Hersam, C. Janin, W. S. Morley, R. W. Postlethwaite, B. R. Putnam, G. McM. Ross, Gustave Schrader, R. Chester Turner, H. W. Turner, and J. F. Wilkinson. S. B. Christy presided. After a full discussion, the following resolutions were passed:

1. The land debt of this Institute should be met as soon as possible; those who wish to contribute may properly subscribe in accordance with their means, and the remainder of the sum should be met by a temporary annual increase of the dues during the term of the mortgage, excepting those members who have already subscribed \$25 or more to meet the debt.

2. Any change of name of the Institute is unnecessary and undesirable.

3. In case a change of name should be voted by the members, the name should be changed to American Institute of Mining and Metallurgical Engineers.

4. The matter of reclassification of members should be postponed until the annual meeting in February 1913.

5. There should be no distinction in dues between classes of members, other than honorary and junior.

6. The standard of membership should not be lowered in any effort to secure a larger membership with a view to a larger income.

7. That a committee of five be appointed to transmit the sense of this meeting to the Council and Board of Directors of the Institute before the adjourned general meeting, October 7, 1912.

The Southern California local committee of the American Institute of Mining Engineers has called a meeting to be held in Los Angeles, September 30, and has sent out the following suggestions for discussion:

A. We recommend that for the present rules of the Council, governing sections of the Institute, there be substituted a constitutional amendment providing for the formation of local sections and specifying the powers thereof, and their relations to the parent body, and granting the largest degree of autonomy consistent with reasonable supervision by the Council.

B. It is the sense of the committee that some adequate provision for geographical representation in the Council of the Institute should be provided. Would suggest that the chairmen of the local sections should become ex-officio members of the Council, and that other members, to the required number, should be elected at large by members of the Institute.

C. We consider that the secretaries of the Board of Directors and of the Council should be elected by these boards respectively, instead of by the Institute at large.

D. By-law 4, paragraph 4, should be amended to read as follows: Neither the secretary of the Council nor the secretary of the Institute shall be the same person as the secretary of the Board of Directors.

E. That provision be made to secure free nomination for the general offices from the membership at large, and that the nominating committee be instructed to propose two or three names for each office in case such number be not nominated by the members. We feel that some provision

should also be made for district representation in all offices, excepting president and vice-president.

F. As to the Board of Directors, while we clearly recognize the necessity of having enough active members residing near New York City, we feel that the policy should be established of securing members of that board, so far as possible, who have had sufficient experience in other parts of the country to enable them to represent the members thereof.

G. We favor the establishing of topical divisions similar to the Iron and Steel Division, under the auspices of the Institute, with headquarters in regions appropriately embracing membership particularly occupied in work relating to the scope of such divisions. A division of precious metals and allied ores should be formed in the West and probably one or more for the copper, lead, and zinc industries in the Middle West.

H. We urge the importance of prompt and effective cooperation of the Institute in the forthcoming International Engineering Congress, to be held at the Panama-Pacific International Exposition, San Francisco, in 1915.

I. We deem it unwise and unnecessary, at this juncture, to increase dues, being convinced that this will be wholly unnecessary if the finances be arranged in accordance with plans now partly in operation.

J. We heartily endorse the action of Mr. James Douglas, past president of the Institute, in soliciting subscriptions as a means of liquidating the mortgage indebtedness, and do hereby pledge our best efforts to secure for this purpose the due share of contributions from members residing in our district.

K. We suggest that the policy should be followed of giving representation geographically upon all general committees, as publication, nomination, and in every way possible of giving members in all parts of the country full opportunity for expression of opinions on matters affecting organization, prestige, and financial and professional administration.

L. We recommend that bi-monthly reports of the proceedings of both the Board of Directors and the Council be distributed to all members with the *Bulletin*, and that the more important acts be announced more frequently in prominent mining journals.

## The Braden Copper Company

The Braden Copper Co. may shortly have to do new financing, according to the *Boston News Bureau*. The company has in its treasury \$1,000,000 7% five-year second lien collateral trust convertible bonds of a \$2,000,000 authorized issue. There are outstanding \$13,000,000 in securities, of which \$6,000,000 is stock and the remainder is bonds. Many predictions regarding the Braden property made some time ago by the management have fallen short of realization. It was thought that between 15,000,000 and 18,000,000 lb. of copper would be produced last year, but not until early in 1912 was production commenced.

The Braden mill has been finally completed with a nominal capacity of 2000 tons per day. Only a 50% recovery has been secured in the new mill, which caused the management to install the Minerals Separation process in the single-unit mill. The result has been most satisfactory, as recoveries have run as high as 90%. It has been determined to equip the three sections of the new mill with this process, and when completed each unit will have a nominal capacity of 600 tons. A recovery of over 85% is looked for. The cost of these alterations will not exceed \$200,000, and the capacity will eventually be increased to 3500 tons.

The smelter will be enlarged sufficiently to handle the concentrate coming from the daily treatment of 3500 tons of ore. This work does not mean that the leaching process has been abandoned; work on the leaching plant, however, has been more or less delayed. Although the latest estimates of Pope Yeatman, consulting engineer, gave the

Braden 23,000,000 tons of reserves, it is understood that the actual amount of developed and partly developed ore is considered nearer 30,000,000 tons. Operations have been retarded of late by caving at the mine, and the mill has not treated its normal capacity. During August but 25,000 tons was run through the plant.

## Katanga Developments

According to the report of G. Campbell, British vice consul at Katanga, as summarized in *The Financial News*, the smelting of the copper ore at Elisabethville is still in the experimental stage. On the arrival of the railway at the Star of the Congo the Union Minière proceeded to set up a smelter at Lubumbashi for the treatment of the ore by blast-furnaces. The smelter started to work regularly in August 1911, and continued until the end of November, when the lack of fuel caused a stoppage, and a delay occurred, which was prolonged by an accident which took place in December. Work was resumed in January 1912, and continued until the end of February, when the supply of fuel again failed. The arrival of 500 tons of coke toward the middle of March enabled operations to be continued for another three weeks. Up to the present time coke has been imported from Europe at the cost of £12 per ton landed at Elisabethville; but an arrangement for the supply of either coal or coke from the Wankie colliery, which is situated on the main line between Bulawayo and Livingstone, is under consideration, while some favor the use of electricity. It is presumed that the board is discussing the question in the light of a report furnished by a special commission which visited Katanga in November 1911, and it is clear to all that expenditure must be decreased if any substantial profits are to be made. None the less, it is disappointing that the work should suffer at the precise moment when satisfactory results are being obtained.

During January and February 1912 over 98 tons of bar copper was obtained; lately the ore has been washed before smelting, with the result that 25 tons per day has been produced. The copper has brought £60 per ton at Antwerp. A small plant has recently been put up for the treatment of the ore by the reduction process, using charcoal, which is procurable in the vicinity, as fuel, and experiments will no doubt be carried on with the plant when the smelter is closed.

Mr. Campbell considers it too early as yet to gain reliable information as to the value of the recent discoveries; but states that it is generally admitted that, with the exception of gold and diamonds, several years must elapse before deposits of minerals, of whatever value, which lie beyond the territory controlled by the Union Minière, can be worked at a profit. A few claims have been pegged out in the district through which the railway from Sakania to Elisabethville runs; but the majority are far distant from transport facilities, and it is obvious that copper, tin, and iron cannot be worked under such conditions. No important gold discoveries have been made of late, as far as is known, while work on the Kundelungu diamond pipes has been so handicapped by lack of labor that no opinion can be given as to their value. Prospectors have, in short, been disappointed; they are aware on their arrival that the country is far from the coast, and that working expenses are bound to be heavy; but they do not take into account the fact that the most highly-mineralized portion of the Katanga, to the extent of one-third of the district, is in the hands of the Union Minière, and as they work their way to the regions beyond the main copper belt they find their difficulties and expenses increase far more than they expect, owing to the high price paid for carriers at Elisabethville and the scarcity of food for the first 100 to 150 miles.

THE Mysore group of mines of British India produced bullion worth \$900,250 during August, the Champion Reef contributing \$210,700 from 18,702 tons, and the Mysore \$361,900 from 25,446 tons treated.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Increasing the Dues of the American Institute of Mining Engineers

The Editor:

Sir—The proposed increase in the annual dues of the American Institute of Mining Engineers from \$10 to \$15 has occasioned grave doubts among many members as to whether it would actually increase the revenue of the society. For it is feared that so many resignations will result, and that it will prove such a formidable bar in increasing the membership, especially from the much-needed younger element, that it will prove a boomerang as a net revenue producer, while it will increase the burden of the 'loyal stayers' some 50%. As I belong to that one-eighth portion of the membership known as life members who paid their dues for life in a lump payment, I feel that my personal opinion should be withheld in a matter that increases the dues of the other seven-eighths of the membership, especially as the energetic 'insurgent committee,' in their very valuable work, produce figures and make suggestions that may render a change in the dues unnecessary.

This same problem has arisen in the history of our other national societies, and the experience of the closely related American Society of Mechanical Engineers is at least helpful in suggesting that there need be no fear of expecting any material loss in the membership or interference with the growth should the dues be increased to \$15 per year. Some twenty years ago, when this much younger society had reached the stage, very much earlier in its career, where the expenses had outgrown the revenue derived from \$10 dues, its executive committee had to face the present condition of the Institute. While some of the committee promptly suggested increasing the dues to \$15, too many members feared the resignations that would thereby result and an effort was made to struggle on with the growing work by paring the expenses and thereby continue the dues at the original rate of \$10 per year. I was then one of the 'conservatives' in this society who greatly feared a heavy loss in the membership if the dues were raised, as so many of the members were young men to whom this would add an appreciable burden. However, my brother, F. Meriam Wheeler, a 'progressive', insisted that if the society was to grow and become of greater value to its members, it must have a larger revenue and hence larger dues. He finally brought the rest of the executive committee to his point of view, and the dues were increased to \$15. The resignations that followed were utterly insignificant, the income of the society was increased almost 50%, and the growth in new members was rather increased, instead of being restricted, by the additional advantages that the larger income permitted.

Portage, Wisconsin, September 18.

### Persistence of Ore in Depth

The Editor:

Sir—My recollection hardly agrees with that of T. A. Rickard, as to there having been a marked change in opinion on this question during the twenty years that have elapsed since the discussion in the *Engineering and Mining Journal*. Then, as now, irresponsible scribblers, or unscrupulous promoters, would frequently refer to the 'known fact' that 'true fissure veins extended to unknown depths, and usually became richer as they went down'; and then, as now, the great majority of scientific observers and experienced miners were non-committal, but inclined to a

contrary opinion. I remember myself contributing a letter to that discussion, controverting one or more particular cases with which Mr. Rickard had fortified his argument. If I remember rightly, I was very careful to say that I did so without any idea of attempting to base a general rule on those or any other individual experiences. I question very much whether we are justified in doing so now.

It seems clear that the more soluble ores, and particularly those of copper and silver, are subject to migration in a manner which usually results in their removal from vein outcrops and redeposition lower down. But neither the zone of leaching nor that of secondary enrichment has necessarily any relation to the present water-level, and while our recognition of the phenomena of secondary enrichment necessarily implies that a zone of primary impoverishment must eventually succeed it, experience at Butte and elsewhere should make us very cautious in forming any hasty opinions as to the limits in depth of these zones. And when we come to gold ores, apart from alteration near the present surface, the evidence of the existence of secondary enrichment is both scanty and dubious. Notwithstanding Mr. Rickard's authority, I venture to think that most gold ores were originally deposited in or very near their present position.

We have some evidence, which accords with our generally accepted notions on the subject of vein formation, that there is a critical horizon where the conditions of heat and pressure favor the deposition of ores. But this is by no means necessarily at the actual surface, and there seems to be evidence that in many cases veins have been followed down through a barren surface-zone to one of primary ore deposition, just as they have been followed down below the zone of ore deposition to one where they are virtually barren. Would it not be as reasonable, in the former class of instances, to assert that veins increase in richness with depth, as in the latter class to say that they became impoverished? Does not Mr. Rickard confuse this impoverishment in depth of orebodies with that of veins? In the former case, sooner or later impoverishment is inevitable; for universal experience shows that individual orebodies are limited in extent in depth as well as horizontally.

I admit that undoubted cases where the zone of primary ore deposition was below the present surface are comparatively rare, but surely there is a natural reason for this: prospectors do not usually sink on barren veins, in order to find out what is below. Ordinarily prudent people, as a rule, only sink on veins which show at the surface evidence of productiveness. As orebodies, however persistent, must terminate somewhere, it is to be expected that those which have been followed down from the surface will play out eventually, and the chances of finding others in depth are by no means as good as they were of finding the original ones of which nature had furnished a section. It is quite possible that, in any given district, if a number of shafts were sunk on barren veins to depths of one or two thousand feet, and a few miles of levels driven corresponding to the openings on the productive mines, valuable orebodies might be discovered. We should be careful to distinguish mentally between the greater difficulty of finding, or the greater expense of extracting, ore at increased depth, and the question as to whether its actual quantity or value is less.

I do not think the evidence of the value of ores raised from any district in depth, as compared with that mined at the surface, can be conclusive, unless all the veins, rich and poor, are developed to an equal extent before making the comparison. The only district where this is being done, or is likely ever to be done, is the Witwatersrand, and the evidence there is variously interpreted. In the first place, it is still uncertain whether the genesis of the ores was such as to entitle us to quote experience there as bearing on the persistence of ore in veins; and, in the second, while it is obvious that the grade of ores now being worked in depth is far lower than that mined nearer the surface, it is by no means generally accepted that the difference may

not be accounted for by the fact that the deep modern mines are taking out the veins *en masse*, whereas the earlier ones confined themselves to the then profitable areas. Surely everyone remembers that many of the outcrop mines were at first regarded as too low in grade for profitable working. It will be time enough to use the Rand as an argument to bear on the general topic, when Rand engineers have reached an agreement as to the facts. Evidence which is to throw light on a general rule must be derived from individual cases; but in any district it is apt to be conflicting, unless one is familiar with it in all its phases. I will confine myself to quoting two districts to which I have given special study.

The principal mining district of Gilpin county has been cross-cut throughout, at an average vertical depth of 1500 ft., by the Newhouse tunnel; the maximum depth reached by sinking on the veins (excepting in one instance) being two or three hundred feet less. The evidence so obtained, together with other evidence from shallow adits and mine cross-cuts, may be summed up in the statement that in depth the number of veins is less, but that in the veins which persist there is no general change in character or extent of mineralization. I make this statement without reservation, so far as it applies to the area centring in Nevadaville, which has been the principal productive area of the district. As to the Russell Gulch district, I am not so sure, but incline to sum up my observations in the same statement, although several individual instances point the other way. The Aduddel-Searle-Kokomo lode, for instance, where driven on at the Newhouse tunnel level, for a length of 2000 ft. shows no commercial ore. At first sight this looks like decided evidence of impoverishment in depth; it must, however, be borne in mind that long stretches of the same vein, as, for instance, one of equal length to the east of the Kokomo shaft, contains no commercial ore at surface. Similarly the rich pipe-like orebodies of the Druid, which occur along irregular fissures, so tight that it is hard to distinguish the fissure where mineralized, have not been found at any point below the 300-ft. level. In view of the nature of their occurrence, and the extraordinary difficulty in tracing them, however, this by no means disproves their existence in depth. Similarly rich pipe-like orebodies have been found at the tunnel level in the Trentina or Wellington No. 6 vein, which has not been positively identified at the surface.

In another district, that around St. Elmo, where gold and silver occur associated with sulphides of zinc, lead, and copper, the orebodies unquestionably are of less size and value in depth. Numerous small pockets of gold ore were taken out at the surface, but while these led to nothing in the form of permanent mines, this may be accounted for on the supposition that the ore was merely pockety, and that such pockets were naturally found only at surface. The most extensive workings in the district are those on the Mary Murphy and Pat veins, the former having been opened through a vertical distance of 2000 ft., of which 1200 ft. from the surface has been thoroughly explored. The ore in depth is obviously of far less value, although not uniformly so. Some ore of very high grade was extracted between the twelfth and thirteenth levels (1000 to 1100 ft. vertical depth), and some is now exposed above the eleventh. But most of the ore in depth, from 500 to 1000 ft. vertical, is of much lower grade in gold and silver than that found in the first 500 ft. The most striking features shown by a comparison, however, are: (a) that the distribution of the precious-metal content in the lower levels is far more erratic, the high-grade ore occurring only in irregular bunches, distinguishable from the low-grade zinc and lead sulphides only by assay; and (b) that the orebodies become progressively less continuous in depth. While it has not been found possible to distinguish any particular minerals with which the gold and silver are associated, it is noteworthy that in the upper part of the vein, and in the lower levels where rich ore is found, there is a great deal of quartz and rhodonite present as gangue. On the other hand, gold and silver are by no means always

present where there is much quartz and rhodonite. Below the fourteenth level (1200 ft.) development so far has disclosed no commercial ore.

The Mary Murphy affords excellent opportunities for observing the character of the ore throughout a great vertical height, both because unsystematic mining methods have left pillars of ore standing throughout the old workings, and also because of the recent discovery of a parallel system of veins, narrower and more irregular than the Mary, but of similar character and grade, which are being worked from the second to the eleventh levels. A similar tendency to impoverishment in depth is observable, as in the Mary Murphy itself. This, then, is a rather striking case of non-persistence of ores in depth; due, in my judgment, to the fact that the primary deposition of the most valuable ore was principally near the present surface. From the fourth level to surface, there is no change in grade; and the unaltered sulphide ore in places extends right up to the grass roots.

Speaking generally, I would say that while the great majority of individual cases justifies the conclusion that mines do become poor in depth rather than the reverse, I deprecate drawing from these individual cases general conclusions as to the actual distribution of ores, from the standpoint of the geologist. From a commercial point of view, the miner does well to proceed with caution from the known to the unknown; the engineer cannot be too skeptical as to the indefinite continuance of orebodies. Economically, Mr. Rickard is doubtless justified in choosing the gold contained in the first thousand or so feet on the Rand, in preference to that in the next ten thousand; but the quantity actually there is another question. In fact, the entire discussion seems to me rather academic.

GEORGE E. COLLINS.

Denver, Colorado, September 16.

## Imports of Copper Into France

Imports of copper into France during the first eight months of 1912 are not only the heaviest in the history of that country, but the percentage of United States copper to the total also established a new record. Of total imports of 122,270,400 lb. from January 1 to September 1, the United States contributed 103,051,200 lb. or 84%. The appended table, compiled by the *Boston News Bureau*, shows total imports of fine copper into France during the first eight months of the years 1907 to 1912, inclusive, the imports from the United States, and the percentage of United States imports to the total (in pounds):

	Total imports Jan. 1 to Sept. 1.	From U. S.	% U. S. to total.
1912 .....	122,270,400	103,051,200	84
1911 .....	94,158,400	71,899,520	76
1910 .....	81,544,960	56,981,120	68
1909 .....	82,418,560	63,616,000	77
1908 .....	106,971,200	84,981,120	79
1907 .....	67,249,280	43,384,320	64

AN exploring expedition consisting of eight members of the Geological Institute of Mexico has, from recent accounts, made some valuable discoveries in the peninsula of Lower California. The expedition was divided into four different parties, each in charge of two of the experts from the Institute. The party under the direction of Dr. Wittich and Dr. Böse pushed on through the central desert region to the great salines around Sebastian bay. Great fields of salt, 60 to 70 square kilometres in area, were discovered, and from the data collected the fact is shown that the Pacific Ocean is in course of rapid retreat from this part of the peninsula. Traces of the comparatively recent presence of the sea were found at an altitude of 3450 ft. Dr. Wittich concludes that even as late as during the prehistoric human period the peninsula was either entirely under water or formed an archipelago.—*Pan-American Union*.

## Special Correspondence

### SALT LAKE CITY, UTAH

CAUSE OF BINGHAM STRIKE.—DEMANDS OF THE WORKMEN.

—MINE-OWNERS CONFIDENT.

Forces that have fought before are lined up for battle in Bingham. On one side is Charles H. Moyer and the Western Federation of Miners, and on the other is Charles M. MacNeill, of the Utah Copper Co., who was one of the active forces in the great Cripple Creek strike of less than ten years ago, in which Moyer was the leader on the other side. Mr. MacNeill is now in Europe, so he will not be able to personally direct the fight against his old enemy, and matters will be in charge of D. C. Jackling.

The cause of the strike which called out about 4500 men in Bingham, September 18, was the demand for recognition of the union and for an advance in wages of 50c. per day, in addition to the increase of 25c. per day granted September 1. The mine-owners thus far have refused to treat with the union, although expressing a willingness to meet committees of employees. Indications are that the strike will be prolonged, the mills at Garfield will be tied up, and the Garfield smelter of the American

BINGHAM GULCH.

Smelting & Refining Co. will be obliged to shut down in part, bringing out between 4000 and 5000 more men, or a total of between 9000 and 10,000.

The fight is far from being impromptu. Bingham has never been a high-wage district, and the Western Federation of Miners has always looked upon it with jealous eyes, even before the development of the Utah Copper Co. gave it the importance it has attained in recent years. The mine-owners have been closely organized for years, and have combatted every move of the Federation. At the time the labor troubles in Colorado were at their height, and large numbers of men from Cripple Creek, Telluride, and other districts were drifting into Utah, the Federation endeavored to get a foothold in Bingham. The mine operators watched every newcomer closely, however, and there was no work for anybody who had a record as an agitator or of having taken an active part in labor troubles. Mine operators all through Utah, in Park City and elsewhere, took this stand, and the 'undesirables' were passed on to Nevada, where they soon made trouble.

In 1906 a strike was averted by a voluntary increase in wages, which were reduced after copper slumped in 1907. Since then the Utah Copper Co. has become more and more the dominant factor in Bingham, being by far the largest employer of labor. The policy of this company has been to do all the work possible with cheap labor, hiring foreigners principally. Something like 90% of the men who went on strike are Greeks, Slavs, Lithuanians, Finns, and others of foreign birth. The Federation has

been steadily fighting for membership, but has made rather slow headway in the face of the opposition of the mine-owners and the difficulties attendant on organizing a conglomeration of many races with many tongues. In fact, a minority of the strikers are members of the union, but the men were stampeded by the agitators.

Trouble has been in sight for some time. The operators hoped to avert it by the voluntary increase of 25c. per day, effective September 1, but this failed to satisfy the men. Charles H. Moyer came on to take command in person, and the vote to strike came at a meeting in which he made a speech. The mine operators are confident of winning this strike. The Utah national guard is too small in numbers to cope with the strikers if they take a violent course. This will mean the prompt calling out of the regular troops at Fort Douglas, adjacent to Salt Lake City. Experience has shown that the regular troops can control violence, and the operators believe that Moyer cannot long hold together the various groups of foreigners.

### NEW YORK

STRIKES AND THE COPPER MARKET.—ANACONDA SHARES.

—COPPER FROM PRECIOUS METAL MINES.

Unexpected elements have added much interest to the copper situation, which now can only be described as doubly double-barreled. The newest feature is evidently a blessing in deep disguise. A short time ago refinery production was retarded by a strike at the Baltimore plant of the American Smelting & Refining Co. and prices advanced. Now the workings of the Utah Copper Co. are held by armed workmen on strike owing to a refusal to grant a demanded wage increase. The follower of the share market has now a most puzzling problem to work out. Utah Copper is a most important producer. The stoppage of its production would make a most decided difference in September figures. Ordinarily such a condition would be considered a catastrophe and shares would have a distinct drop in the market. On the other hand, refinery production has been increasing, and last month's output was ominous in its possibilities. A growing surplus would cool the buying enthusiasm of consumers. If, however, curtailment can be effected without agreement on the part of producers, metal prices should, and probably will, go still higher, and the general copper share list rise in proportion. There is some comment concerning a possible 'runaway' market, and of efforts on the part of producers to prevent such a result. It is difficult to see just where a runaway market would start in the face of a production that breaks all records and could still be easily maintained above the average of the past two years even with the output of Utah Copper cut off. If the strike should spread to the other Guggenheim properties and Nevada Consolidated, Ray, and Chino be temporarily closed, then the only avenue for the producers who are trying to prevent a runaway market would be to let a little of the copper prosperity spread to the workmen. The copper situation is fundamentally based on exactly the same controversial elements as are all political and economic questions—the struggle for an equitable distribution of wealth. The company's treasury needs a surplus, the stockholders need dividends, the miners and laborers need increased compensation. There is insistent clamor, at any rate, whether the need is there or not. The entire copper situation is most interesting, and it is undoubtedly true that never before has any group of manipulators succeeded in carrying such a tremendous deal to a similar point of progress. The public does not yet know how successful a market has been made for the metal. The price has been advanced and is held with great apparent firmness. What has been done with all of the copper is not a matter of public record.

The chief issue in the Bingham difficulty seems to be recognition of labor organizers—what used to be known as the 'walking delegate'—rather than a wage question pri-

marily. The original demand of the miners was for an increase of 50c. per day. Half of this demand was granted on September 1, and the present strike is on the ground that miners do not propose to be satisfied with 'half a loaf.' Copper Producers' figures will be affected not alone by the strike in Utah, but as well by the cessation of shipments from Cananea. The conditions along the Mexican border appear to grow worse rather than better, and the copper which is derived from Mexico will undoubtedly have to be deducted for the next two or three months. The Utah Copper Co. is to turn consumer of its own product. Plans have been completed for the electrification of the Bingham & Garfield railroad and all of the power mechanism operated in the mine at Bingham, in the smelter at Garfield, and the various pumping plants. The power will be derived from the Telluride Power Co. The manufacturers of steam-shovels are said to be working on devices to use electric power instead of steam pressure.

There is a good deal of market capital being made out of the expected action of the boards of directors of the Amalgamated Copper Co. and the Anaconda company. Both issues are being manipulated to higher levels, and the possibilities of greater income returns are being exploited as much as possible for market purposes. The Anaconda company states that its High Ore shaft is to be sunk to the 3400-ft. level. Its present depth is 2800 ft., which is the deepest working in Butte.

The Ahmeek Mining Co. is continuing to conform to precedent and has declared a quarterly dividend of \$6 per share. Each dividend that Ahmeek has declared since it commenced distribution has been an increase over its previous payment. The previous dividend, which was paid in July, was \$5 per share. Recent developments in the way of copper production at Cobalt are worthy of notice. The Timiskaming Mines Co. recently made a shipment to the American Smelting & Refining Co. of 30 tons of ore which contained 400 oz. of silver per ton. In addition to the silver, the ore carried 3% copper, and the Timiskaming company received \$150 for the metal. This is the first payment on record made to a Cobalt property for copper. If, as has been foretold from time to time, Goldfield, Nevada, should develop into an important copper producer, it would be a noteworthy coincidence that the two best known of the precious metal districts in the country should develop into copper producers.

Wall Street has been interested in the acquiring by New York banking interests of the old Manning & Mackintosh claim against the Mexican Government, amounting to more than \$50,000,000. As the Mexican Government is in such an unstable condition at the present time, it is to be presumed that Wall Street was able to acquire its part in the claim at a very considerable discount. N. L. Amster has purchased the San Jose de Sonoyta grant in Mexico on the Sonoyta river, consisting of some 5000 acres, valuable for both mineral and timber, but the principal present value of the property is its water rights, which will provide for all of the needs of the R. R. R. mine. An interesting organization has recently been perfected, headed by Samuel E. Adair, who was formerly an associate of the late H. H. Rogers of Standard Oil fame. Mr. Adair, working with a group of capitalists in New York and Philadelphia, has taken over a mining concession in Brazil covering 60,000 square miles, said to be richly mineralized. A unique feature of the company's work is that there is to be no stock offering. The properties will be worked entirely by leasing, on a 20 to 25% royalty basis.

### BOSTON

DECLINE IN LAKE SUPERIOR SHARES.—LAWSON AGAIN.—  
HYDRO-ELECTRIC CONSOLIDATION IN UTAH.

The decline in Lake Superior copper shares has been worrying Boston considerably of late, as the movement is believed to represent something more than a mere transient phase of the market. It is feared that the leaven of Mr. Finlay's estimate of the district is at last be-

ginning to leaven the whole lump. The decline of mid-September was not confined to Wolverine and the Dow stocks, but included nearly every stock in the Lake list except Ahmeek. Notwithstanding the high copper market and with every incentive to recovery, Boston has recently seen Calumet & Hecla selling 20 points below the year's high mark, Wolverine 37, Lake 14, Copper Range 9½, Mayflower 6, Old Colony 5, Allouez 4½, Isle Royale 3¾, Quincy 8½, Adventure 3½, Superior 5¾, Hancock 13, Osceola 21, Centennial 10, and the Dow stocks—Franklin, Indiana, Algoma, and North Lake—8¼, 8, 5, and 4, respectively. The weakness of all Lake shares has cast a gloom over the entire market. In mixed metaphors it may be said that the Lake situation is the one fly in the copper ointment which wet-blankets the market. For three generations the New England investing public has followed the Lakes, but it seems that their glory is departing.

Interest in the Ely district is also being revived by the activity on the Curb of Smokey Development Copper, an issue which is being handled here by Gay & Sturgis. Advices from Ely state that Smokey Development is showing good progress, the ore being good grade for over 100 ft. in the adit. Ely interests are predicting that Smokey Development will present the same possibility as Nevada Consolidated did at \$5 per share and Cumberland-Ely at 25c. per share.

People have been wondering when and where Lawson would break out next. His stocks here have all been neglected, so far as he is concerned. Nobody has been able to say what would be the character and extent of his forthcoming eruption. Now it is announced that he will take up his war against the 'System' at the point he left off five or six years ago. The story will be resumed in *Everybody's Magazine*. *Everybody's*, a year or so ago, passed within the control of the Butterick corporation and was supposed to have modified its sensational attitude toward Wall Street with that transition. Now it appears that the magazine is to take up its 'muck-raking' again after the same fashion as when Ridgway and Thayer bought the moribund monthly from John Wanamaker, who could never make it profitable. The publishers engaged Lawson, who was then itching to expose the Amalgamated transaction, to write it up in serial form for *Everybody's*. Lawson was willing and made a great hit with his story, 'Frenzied Finance.' Following the Amalgamated flotation came the life insurance scandals, and Lawson continued his crusade in that field. Two or three years afterward he published his story, 'Friday the Thirteenth,' and later on his farewell to militant financial reform literature appeared in *Everybody's*, 'Why I Gave Up the Fight.' Now Lawson is to take up the dropped threads and is said to be more spectacular than ever. He proposes to show that 'sure-thing' gambling on the Stock Exchange is the real cause of the high cost of living, and will bring out his famous 'Remedy,' proposing to carry out his long-cherished intention of putting the Stock Exchanges 'out of business.'

The recent successful flotations of Pond Creek Coal, Butte & Superior, and Alaska Gold Mines by Hayden, Stone & Co. are to be followed in the near future by another offering, that of Telluride Power Co., unless the Bingham strike postpones the matter. The Telluride company is to be reorganized, with D. C. Jackling as president, and the plans of the banking house here are to bring about a consolidation of practically all of the hydro-electric power-plants of Utah and southern Idaho. The meeting of the company will be held in Chicago on October 1, at which time the capitalization is to be increased and a bond issue authorized. Several million dollars will be spent in building new plants and improving old ones. It is proposed to make the hydro-electric service for the mines, mills, and other industries of the intermountain country comparable in importance to the hydro-electric lines of California which serve the mines, smelters, and other enterprises of California and Nevada. The reorganized company is preparing to enter into a contract to sup-

ply Utah Copper with power at a cost of about \$500,000 per year, which will reduce the expenses of the mining company about \$100,000 per year. The generating capacity of the proposed consolidated plants will be 125,000 hp. Reed Smoot, David Eccles, and Jesse Knight are interested. While the new financing will be directed from Boston, it is understood that the control will be held in the West.

Wolverine since its 20-point slump has been the subject of all kinds of rumors. One rumor was to the effect that it would take over Mayflower and Old Colony. Wolverine is a New York copper and the others are Boston issues. Until a few months ago Mayflower and Old Colony were under the management of Harry F. Fay. But Fay was outvoted on Mayflower by the St. Mary's Mineral Land Co. faction, and Charles J. Paine, of Winona, and St. Mary's Mineral Land Co. succeeded Fay as president. Physically, the expansion of Wolverine by taking over these next-door neighbors would be a logical move. Wolverine is a small property and could well afford, it seems, to follow the example of Calumet & Hecla, Copper Range, and Quincy in expanding. It is a pity that Wolverine did not acquire control of Mayflower and Old Colony last year, when they could have been had so cheap. Last year Mayflower sold down to 25c. and Old Colony to 50c. per share. The whole capitalization of the one could have been bought for \$25,000 and the other for \$50,000. Such a move, considering the developments which have since been made by the drills in Mayflower and Old Colony, would have made Wolverine one of the most brilliant speculations in the copper-share market here this year. Instead, it is now looked upon as approaching extinction, with the management indisposed to do anything to perpetuate its excellent name and organization. Wolverine could probably be amortized for around \$100 per share, as the pillars in the drifts constitute an asset which has not been fully calculated. The company also has money in the treasury and quick assets in machinery. The debilitated condition of the Lake market is such that a consolidation of Wolverine, Mayflower, and Old Colony would be just the tonic needed. But it is a difficult matter to join two rich prospective properties with one whose days are numbered, even though it has a brilliant history in low-cost production and dividend payments.

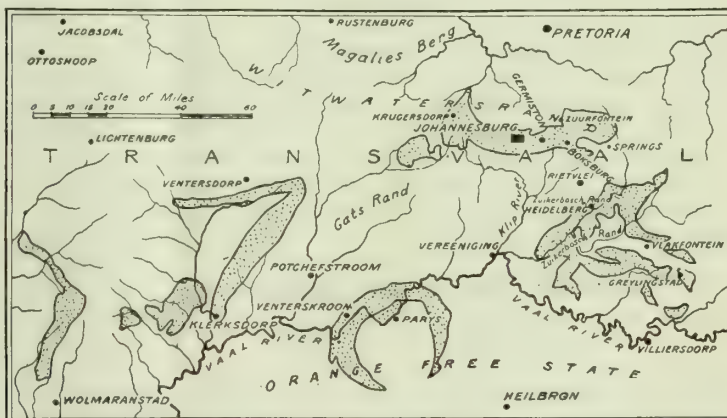

### JOHANNESBURG, TRANSVAAL

ECONOMIES FROM CO-OPERATION.—LOWER WORKING COSTS.  
EXTENSIONS OF THE RAND.

The Rand gold-mining industry will not suffer severely from the incubus thrown upon it by the Miners' Phthisis Act, which is estimated to mean an additional cost of a million sterling to the mines. Relief from this tax on the mining industry is to be found in the proposed co-operation among the mines in the matter of recruiting unskilled labor; the different groups having hitherto foolishly been in open competition in the labor market. The natural result has been that higher prices have been paid for negroes and higher wages offered to attract the negroes to the mines. It is expected that if the new arrangement is adhered to by all the different groups, the total saving ought to practically reach the same amount as the extra impost about to be cast on the mines through the coming into force of the Miners' Phthisis Act. The Railway Administration has also announced a reduction of 1s. 3d. per ton on the railway rate for carrying coal from Witbank to the gold mines on the Rand. Witbank is the principal centre now supplying coal to the gold mines, and as about 250,000 tons of coal per month is being used by the gold mines alone, this means a saving of about £200,000 per year in the fuel bill of the gold mines. This

will be an additional compensation for the effects of the phthisis act. If, however, the mines and the Government would co-operate and induce or compel the miners to properly observe the mining regulations, there is every prospect that the better method of recruiting negro labor and the lower freight rate on coal to the Rand would result in an important reduction of costs; not perhaps to a record low level, but at all events to a shilling per ton lower than the prevailing costs of working.

The absolute necessity for lowering the working cost per ton milled appears to have been somewhat obscured by the adoption of selective mining; that is, mining the ore best adapted to increase the profits. This policy, of course, can be carried to the same extremes as sending waste to the mills, with the object of reducing the average working cost per ton milled, and both practices have been known to exist on the Rand. Selective mining tends to defeat its aim because it almost invariably results in a material addition to the working costs. After all, its benefits are of a transient character, impossible to maintain over the whole life of the mine, with the result that the duration of the mine is shortened and its latter days

OUTCROPS OF THE RAND SERIES.

constitute a continuous struggle with an attenuated yield.

It was at one time thought that the adoption of coal-mining methods by aiming at a large output and low working costs per ton, would materially add to the profits of the Rand, and several coal-mining experts have been imported from England to bring about this much-needed economy. Unfortunately for the mines, the high salaries offered attracted the wrong type of men, who have been managing directors rather than practical mining engineers, with the result that the cost of mining has not decreased to the extent anticipated. What the Rand really requires is practical underground engineers, good organizers, men of sound knowledge acquired by practical mining. Those introduced have failed to meet these requirements, being more suited to lecture on mining subjects than to go underground and introduce practical economies. That Rand mining bears many striking resemblances to coal mining is true, but only to the most difficult types of coal mining. It is therefore necessary that a consulting engineer should be well versed in coal and metal mining, and above all be a good organizer and practical miner. If men of this type were introduced on the Rand, material reductions could probably be made in working cost, and the uneasiness felt at certain properties over impoverishment in depth would be removed by the adoption of better methods of mining.

The Chamber of Mines returns for the month of July record a total output of 766,338 oz. of gold, of which no less than 735,941 oz. came from the Rand. The value of the Rand monthly output alone is now over £3,000,000, and in July (a 31-day month) it was declared at £3,126,077. The outside districts only contributed 30,397 oz. to the Transvaal gold output in July, and on the whole the

gold output of the Transvaal, outside the Rand, can scarcely be considered satisfactory. There has been in progress lately an interesting discussion as to the probability of finding elsewhere in the Transvaal an extension of the Rand banket deposits. Seeing that the Rand gold-field forms the outcrop portion of an extensive irregular basin formed by surrounding bosses of granite, it might be thought probable that extensions of the Rand beds would be found beyond these granite bosses. Vestiges of extensions are claimed to have been found, but they are mostly identified with the lower, or unproductive, portion of the Witwatersrand beds, and all attempts to discover any indication of the upper or productive division of the Witwatersrand have hitherto ended in disappointment and failure. There is, of course, no reason why similar basins should not be found in other parts of the Transvaal, as beds of undoubted Witwatersrand age extend for almost the entire length of Swaziland on the Transvaal side. Unfortunately, these are all Lower Witwatersrand beds which as yet have not been proved to carry continuous profitable veins. In the Orange Free State an extension of the Lower Witwatersrand beds has been proved for many miles by the New Rand, Ltd., but as yet the upper or productive series is entirely absent. There is also the question as to whether, if found some distance from the Rand, the veins would prove profitable. In the neighborhood of Parys, in the Orange Free State, where the equivalents of the Rand productive banket outcrop, they are low grade and altogether too patchy to be workable. Taken on the whole, the prospects of finding another Rand in the Transvaal are not bright, but nevertheless there are several who still consider it possible that such a discovery may be made.

### BLACK HILLS, SOUTH DAKOTA

VICTORIA MILL STARTS.—JUDGMENT AGAINST MINNESOTA MINES.—WORK AT THE WASP.

The Victoria mill has been started, and everything about the plant is working in excellent manner. About 100 tons per day is now being treated, but this will be gradually worked up to 200 tons, which is the full capacity of the leaching department. The Reliance mill has been started, under the management of F. C. Bowman, after some small changes in the mill had been completed under his direction. Judgments amounting to a little over \$20,000 against the Minnesota Mines Co. have been liquidated by a group of the stockholders of the company. This is the first move in a plan to resume operations at this valuable property. Funds are now being raised to start development. The mine is equipped with a first-class hoisting and air-compressing plant, and the wet-crushing cyanide mill has a capacity of 150 to 175 tons per day. The property is at Maitland. E. Major is manager. The Bismarck mill, at Flatiron, will, according to F. B. Hitchings, the general manager, be in operation in sixty days. The plant will have a capacity of 300 tons per day and is modeled along similar lines to the Wasp No. 2, its nearest neighbor. In fact, both properties have the same character of ores.

The Wasp No. 2 company has erected some flat-bottomed ore-bins in the open-cut, into which the mine-cars will be dumped. Skips which deliver the ore to the mill will be filled from chutes in these bins. This will facilitate work as well as give a little extra storage for ore. The steam-shovel is being kept busy stripping, it being the intention to strip enough ore to keep the mill supplied while the shovel is shut down during the winter months. Where the shovel is now at work, on the north side of the open-cut, the stripping is 10 to 14 ft. thick, consisting of sand, rock, and shale. A Donaldson tilting-furnace, made by the Denver Fire Clay Co., was lately installed in the refinery, and is giving excellent service, using Wyoming oil for fuel. Coke furnaces were previously used for melting the precipitate.

E. J. Hoover, of Boise, Idaho, has secured the Golden

Gate property, in Blacktail gulch, and a crew of men is employed cleaning out and repairing the old shaft preparatory to starting extensive development. The property has been a producer of a large quantity of refractory silicious ores, most of which were treated in the old Ros-siter mill, at Deadwood. Nothing has been done at the property for twelve years, and the new owners hope to develop medium-grade milling ores which were untouched during former operations.

Work on the 600-ft. level has been discontinued at the North Homestake property, at Maitland, and it is announced that work will soon be started on the 300-ft. level, where a drift will be run northeasterly to tap the refractory silicious ores lying on the quartzite. This will give a large area of stoping ground. The Black Hills Standard company, a local corporation of which mention has already been made, has started its mill, and is operating steadily, handling 100 tons per day. The mill is in charge of C. G. Willard, for a number of years connected with Lundberg, Dorr & Wilson.

### SUDBURY, ONTARIO

MINING IN THE WEST SHINING TREE DISTRICT.—RESULTS FROM VARIOUS PROPERTIES.—THE OUTLOOK.

There has been more activity in the West Shining Tree gold district, north of Sudbury, than last season, but there is no boom, as had been hoped and predicted by many people. The result of the winter's work and the active work of last summer did not prove a big gold mine in the district, but it gave great hope to the men on the ground and has resulted in further prospecting, and development of the already located properties. A number of engineers visited the district in the fall, but they did not advise their clients to buy any properties, because of the high prices asked, and the stiff terms required. Two options were taken on the Fred Gosselin property by different parties, and both have been relinquished after paying about \$10,000 for the options and doing considerable development. The impression is that the property is of value, but the conditions did not make it possible to justify the high price asked, \$300,000, within the short time allowed by the option. At any rate, Fred Galvin and Victor Rakowsky, of Duluth, have left the property, as the second payment of \$15,000 is about due. The shaft was sunk 55 ft. and a good deal of surface work done. The failure of this property to interest the outside investor has had the effect of keeping other investors and operators from the district for the time. The Gosselin property is in Churchill and Asquith townships. In McMurchie township the Bennet property is reported to be opening well, as also are the adjoining Jefferson and the McIntire & McDougall properties. W. McVittie, of Sudbury, has taken an active interest in the Thomas Seville claims at McMurchie, and after an inspection decided to continue development. Other properties that are attracting attention are the Clark and Caswell claims at Asquith. The Clark claims show an extensive area of mineralized quartz, with copper and galena. Some fine-looking gold specimens have come from the McQuire claims, near the Clark group.

In general, it may be said that the area has been extended by the work of this season, and a number of new prospects have been found within the already known gold-bearing area, but there has been little progress made toward proving any of the deposits sufficiently large to be profitable. For free gold specimens this area is equal, if not superior, to the Porcupine district in its early days. What Shining Tree needs is work, and until something is done the outsider is likely to devote his attention to other fields. The district is now easily reached by a gasoline motor-boat in a day. A Government railroad from Porcupine has been surveyed to the district, and this is likely to be built soon. A wagon-road to the district is also being built which will be only 20 miles in length from the railroad.

## General Mining News

### ALASKA

#### CORDOVA

The Bureau of the Census has issued its estimate of the population of Alaska in 1910, which gives the first judicial district, including Juneau, Ketchikan, Skagway, and others, a population of 15,216 persons; the second district, including Nome, Kuskokwim, St. Michael, and others, 12,351; the third district, including Bristol Bay, Cordova, Kodiak, Valdez, Kenai, and others, 20,078; and the fourth district, including Fairbanks, Otter, Circle, Koyukuk, Tanana, and others, 16,711; making the total population of Alaska 64,356 persons.

Seventy tons of supplies for the Government expedition to the Bering coalfield has gone adrift on a scow

KATALLA OILFIELDS, ALASKA.

and will probably be lost. Beginning October 1, the winter routing of the mail for interior Alaska will be resumed at the Cordova postoffice, and until November 24 there will be two mails weekly from Cordova and Fairbanks. From this date to March 24, there will be three mails of 1200 lb. each weekly. Father Bernard Vaughan, an English Jesuit, has spent some time in Alaska of late, and said that he found the miners to be a hearty, honest, good-natured, and open-handed class of men.

#### NOME

The Miocene Ditch Co., controlled by the Pioneer Mining Co., has started a suit against the Wild Goose company for \$1,500,000 for having diverted the waters of the Nome river during the past six years, and alleges that these waters were acquired by the Miocene company under rights obtained through the Champion Ditch Company.

Telegraph advice states that a rich find of placer gold has been made on Boulder creek, six miles from Nome. The ground yields \$2.50 per pan, and great excitement prevails. It is thought that an extension of the third beach line, which has yielded so much gold, has been discovered.

### ARIZONA

#### GILA COUNTY

(Special Correspondence.)—Churn-drill hole No. 3, at the South Live Oak, is 780 ft. deep, and is reported to have passed through ore for 40 ft., with an average of about 2% copper, though some samples went nearly 3%. At the Copper Reef mine, 12 miles south of San Carlos, the drift from the California adit, on the California vein, has disclosed the ore-shoot for a length of over 200 ft., and the face is still in ore. It is reported to have an average width of 10 ft. and to contain 3% copper and \$8 per ton in gold. A raise is being driven to the surface, a distance of 220 ft., and is now up about 160 ft. A winze has also been started on the ore, and is down about 30 ft. About 25 men are employed.

Globe, September 14.

(Special Correspondence.)—Old Dominion produced 2,597,696 lb. of fine copper in August with four furnaces in continuous operation, compared with three furnaces in July. Preparations are being made to move the old buildings near the main shaft to make room for the new crush-

ing plant, sampling mill, ore-bins, and conveyor-houses, and excavation for the crushing plant has been started. A skip-pocket is being cut at level 14 preparatory to replacing cages with skips for hoisting ore. Similar pockets will be cut at No. 8, 12, and 16 levels. This work must be done and the change made in the method of hoisting without delaying or interfering with hoisting of ore, and therefore proceeds slowly, so that it will probably be eight months before it is finished. About 1200 men are employed. The Inspiration Copper Co. has three Velie motor trucks at work hauling supplies from the town of Miami to the mines, distances of one to three miles. They are of 1500, 3000, and 6000-lb. capacity, respectively. Records were kept of the last machine. It made trips daily at a cost of 48c. per ton-mile, of which 24c. was for labor and depreciation, 13c. for repairs, and 11c. for fuel and oil; being 9c. per ton-mile less than the cost of hauling by teams. The mine officials are quite satisfied with the work of these trucks.

Globe, September 19.

#### GRAHAM COUNTY

The Arizona Copper Co. produced 1630 tons of copper in August.

#### MOHAVE COUNTY

The mill at the Mocking Bird mine has been working intermittently, and the cyanide plant has not started yet. Burke and associates, leasing at de la Fontaine mine, have shipped 50 tons of zinc ore to the smelters. They also have 50 tons of lead ore and 40 tons of screenings on hand. The tungsten mines in the Acquarius range are reported to show good ore, the average shipments being 70% ore, and the average as broken in the mine being 10%. The Golconda is shipping 1400 tons of rich ore per month to the smelter in Oklahoma. The mine is in good shape.

#### SANTA CRUZ COUNTY

Immigrant and customs inspectors have been on a tour as far west as Ajo, about 200 miles from Nogales, and report great activity in the old mining districts visited. About 300 men are working at Ajo, which has been practically dead for some years. The C. & A. Mining Co. has 50 diamond-drill men prospecting the district. Many Mexicans and Indians are employed in that part. An automobile service is in operation between Ajo and Gila, about 45 miles across the desert.

### CALIFORNIA

#### AMADOR COUNTY

The ninth quarterly report of the Lincoln Consolidated Mining Co. shows that receipts amounted to \$15,794, and expenses were \$12,666, leaving a credit balance of \$3128. To date receipts have totaled \$103,454, and expenses \$100,327. Everything about the mine is in first-class working order. New gear, pinion, and cable have been fitted at the hoist. A long-time power and water contract has been arranged with the Pacific Gas & Electric Co., at a favorable rate, under which that company agrees to furnish additional transformer capacity. J. Surface, Ione City, California, is now a director.

No work was done on the 800-ft. level during the past quarter, as all the transformer capacity was required for other parts of the mine. Driving will be resumed in the east cross-cut from the north end of this level later on. The westerly drift in the west cross-cut of the 1200-ft. level has been driven north for 152 ft. in low-grade ore; and work has been stopped for the present. The south drift on the 1950-ft. level has been extended 857 ft., making it a length of 1988 ft., and is now in a fine vein with good walls, which is thought to be the main Wildman vein. Probably the drift is now under the north orebody of the Wildman mine. The latter shaft is full of water and cannot be explored at present. The Wildman's south lode, 160 ft. wide, is some distance south of the shaft, and it will take the Lincoln people about three months to get under where it was found on the 1400-ft.

south level of the Wildman, this being the objective point, where good ore in large quantities is expected. The east cross-cut from the 1950-ft. level is in 802 ft. in black slate and small veins of good-looking quartz.

#### CALAVERAS COUNTY

(Special Correspondence.)—The 40-stamp mill at the Angels mine is working steadily. Fair-grade ore has been opened at a depth of 850 ft. The shaft at the Lightner has passed the 1050-ft. point and is making fair progress. It is reported that an Eastern company has taken an option on the Tulloch mine for \$65,000. The property is at Albany Flat and is being worked under a bond by J. F. Curtis, who offered it to Eastern people. Fair-grade ore has recently been found. The Calaveras Copper Co. has everything in readiness for early smelting at Copperopolis, and it is planned to commence heavy production shortly. Another copper property, the Pool, at Nassau, is to be placed on the operating list, according to recent reports. Some good ore has been developed, and it is proposed to sink deeper.

Angels Camp, September 21.

#### INYO COUNTY

(Special Correspondence.)—During the month of August the mill of the Skidoo Mines Co. treated 1142 tons of ore, with a yield valued at \$17,613. Operating costs were \$6837 and development \$1232, leaving a net profit of \$9545. The mill lost 10.83 days during the month.

Los Angeles, September 24.

The Foreign Mines Development Co., of London, England, successors to the California Trona Co. at Searles, is to resume work at the Borax lake mines. These deposits of trona, or carbonate of soda, cover 40,000 acres of unpatented land in San Bernardino county, and 800 acres in Inyo county. Litigation between these companies has ceased.

#### LOS ANGELES COUNTY

The Republic Smelting Corporation has been organized under the laws of Arizona, with head office at Parker, Arizona, and business offices at Los Angeles. The company is capitalized at \$7,500,000, of which \$1,500,000 has been paid for the property. The officers are: F. C. Fenner, president; W. J. Robinson, treasurer; R. G. Munn, secretary; and J. A. Chestnut, vice-president and general manager. W. W. Wishon will serve as consulting engineer and S. J. Gormly as metallurgist.

#### NEVADA COUNTY

(Special Correspondence.)—A rehearing was recently granted in the case of the Champion Mines Co. v. the Champion Gold Mining Co., and both sides are preparing for the fight. The case involves title to the Champion mines in this district, now being worked under bond and option by the North Star Mines Co. The latter company appears to have no fear of future legal trouble, and continues development work. At its main properties, the North Star company is working as usual. The 80-stamp mill is operating on good grade quartz from the Central workings. During the first half of the year \$100,000 was distributed in dividends, and to date the North Star has disbursed \$3,586,989. Unwatering of the Oustomah is progressing. Klinker brothers, of Los Angeles, have a bond and option on the mine. The lower adit at the Native Son, near Blue Tent, is in over 400 ft., and is expected to intersect the vein about 400 ft. farther in. Hand-drills are used and the work progresses at an approximate rate of 15 in. per shift. J. H. Bishop is manager. Klinker brothers report the finding of pay-gravel at the Oak Flat, above Columbia hill. The adit is being extended to prove the channel. The gravel is of the blue variety, and by some is thought to be the continuation of the Bald Mountain channel. The erection of the new cyanide plant at the Pennsylvania mine, Grass Valley, is about to start. Preliminary grading is practically complete. Development in the mine is reported to be consistently satisfactory. Walter and Garret Biglowe, of Oakland, are arranging to

reopen the old Siberia property, near Badger hill. The mine was a fair producer several years ago.

Nevada City, September 15.

#### YUBA COUNTY

(Special Correspondence.)—In many mining districts in California numbers of dumps of low-grade ore have been left by miners who have prospected for a higher-grade ore before erecting stamp-mills. Sometimes this better grade was found, but the low-grade dumps were covered or left as too poor for milling. At the Pennsylvania mine, at Browns Valley, J. C. Campbell has erected and is working a 9-ft. Beer roller quartz mill to treat the large dump partly shown in the illustration. This mill is a success, and two more are now at work. The dump consists of quartz and country rock of porphyritic diabase, averaging \$3 per ton from test runs. The Beer mill is driven by a 20-horse-power gas-engine at 30 r.p.m., and grinds about four tons per hour through a 24-mesh screen. Both

BEER ROLLER MILL AT PENNSYLVANIA MINE.

inside and outside amalgamation is used, the latter being made efficient by the addition of a 55-ton Pierce amalgamator for saving floured mercury and fine gold.

Browns Valley, September 18.

#### COLORADO

##### DOLORES COUNTY

From July 25 to August 25 the Rico-Wellington company shipped 1340 tons of ore, which returned \$27 per ton net from the smelter. The company has leased the Rico Mining Co.'s mill, at Rico, for five years. It was built for the treatment of zinc, lead, and silver ores, but is not adapted in its present form to the Rico-Wellington ores. Tests have been made for some time past on these latter, and 250 tons was taken averaging 15.65 oz. of silver, 24.4% lead, and 32.13% zinc. Two products were made, zinc and lead concentrate, assaying (1) 45.58% zinc, 5.8% lead, and 5.6 oz. of silver; and (2) 55.9% lead and 31.6 oz. of silver. Out of 100 tons of ore there would be 52.5 tons of zinc and 32.4 tons of lead concentrate. About 10,000 tons of this ore is ready to be mined. It will cost \$21,500 to remodel the mill. To the present two crushers, three rolls, two Huntington mills, and 10 Wilfley tables, will be added one tube-mill, five Deister tables, six Callow tanks, two Callow screens, four pumps, and several elevators. The mill will be driven by electric power, and may exceed 75 tons per day.

##### JEFFERSON COUNTY

(Special Correspondence.)—The experimental plant at the Colorado School of Mines is now equipped with the concentrating unit, and as the second quarter of the appropriation, amounting to \$12,500, will be available by October 1, complete equipment for all the units is promised before the end of the year. C. T. Durell has been making tests with flotation on Colorado zinc ores, and apparatus has been arranged in the plant in advance of the

completion of the permanent equipment. Last year a course in coal-mining was added at the school, as it was felt that more time should be devoted to instruction on this subjection, considering that Colorado employs 15,000 men and produces 12,000,000 tons of coal yearly. Twenty-two men attend the coal-mining classes. Most of the coal-fields are easily accessible to students.

#### GILPIN COUNTY

At a depth of 245 ft. in the Gilpin Orion property, a vein of copper ore 6 in. wide and assaying \$160 per ton has been cut. The shaft will be continued to 300 ft., when the mine will be opened at this depth. S. Laner and associates, working the Columbia lode on Quartz hill, have shipped 10 tons of smelting ore, averaging \$35.50 per ton, from a winze sunk below the 200-ft. level. The local people working the Troublesome mine, on Winnebago hill, are mining ore worth \$35.50 at the 180-ft. level. Shipments from the Bates mine, in Chase gulch, and the Pittsburgh mine, Lake district, have returned good averages in gold, silver, and copper. From the latter mine 50,000 to 60,000 gal. of water is being pumped daily.

#### LAKE COUNTY (LEADVILLE)

Based on the present output of 150 tons of spelter per day from Carbonate ores, it is estimated that Leadville will produce 109,000,000 lb. of spelter this year, compared with a total output of 94,607,456 lb. from the whole state in 1911. During August the New Monarch company sent out 101 cars of medium-grade ore from different levels in the Cleveland and Winnie. From 500 to 600 ft. of development was done, and 80 men are employed. The Winthrop company, at English gulch, has several carloads of machinery ready to be taken to the mine as soon as the Colorado & Southern railroad has built the spur line. Lessees on the Fryer hill mines are busy. Ore averaging 30 to 40 oz. of silver per ton, with some lead and gold, is being shipped from the Adelaide through the Yak tunnel.

#### TELLER COUNTY (CRIPPLE CREEK)

The present flow from the Roosevelt drainage tunnel is 11,000 gal. per minute. On No. 9 level, 1000 ft. south of the Lee shaft of the Isabella, lessees have cut 8 ft. of ore assaying \$41 per ton. They have also opened a rich shoot on No. 8 level. All the lessees at this property are doing fairly well. A 30-hp. electric hoist has been erected at the Mary Cashen shaft, while several machines have been started on a cross-cut to open some of the known orebodies. A 15-hp. electric hoist is also being erected on the Lottie claim of the Stratton estate. The Portland company has put in a 60-hp. electric hoist to scrape into one of the old stopes dry tailing from the mill. The Blue Flag mill is treating 125 tons per day with a high extraction. First-class concentrate from the Portland mill is being shipped to Colorado Springs for treatment.

### IDAHO

#### IDAHO COUNTY

Machinery has been ordered for the American Eagle mine. The Rio Tinto company, which has an option on this property, is to sink a shaft 500 ft. near the mouth of No. 1 adit, where a rich shoot was found when the mine was worked some years ago. A raise will be driven from No. 2 to No. 1 adit. A. W. Boyd, the former superintendent of the mine, is in charge. The Last Chance mill has plenty of water for power and plenty of ore for crushing. A rich shoot has been opened at 300 ft. in the Center Star mine. The mill at the South Fork is again at work after a shut-down for repairs. At the Clarence Ray claim, in the Buffalo Hump country, the adit was driven 350 ft. in hard granite, and has cut ore of good grade. The lode at the Mascot has been opened by an adit 300 ft. long, besides by open-cut. It is 6 ft. wide and oxidized, suitable for a Huntington mill, and a 3½-ft. mill has been erected. It is driven by water-power. At present only copper plates are used for saving the gold.

#### SHOSHONE COUNTY

The Federal Mining & Smelting Co. has acquired the Wilson-Mackay property adjoining the Standard mine at Mace. The price paid is said to be about \$250,000. The Federal company has held several options on the claims, but has allowed them to lapse, up to the present deal. The old bunkhouse of the Bunker Hill & Sullivan company was burned down on September 14. The Yankee Boy mine, on Big creek, has been leased to F. Barker and W. Hughes, who have started active operations. Visitors from the East have inspected the Amazon-Dixie property, which is situated near the summit of the mountains which divide Idaho and Montana. At present 16 men are employed. Ore outcrops for 960 ft. and is being developed at 200 ft. from the surface by an adit, where the lode is from 6 to 60 ft. wide. About 1656 ft. of a lower main adit has been completed. The surface has been equipped with necessary plant and buildings.

### MONTANA

#### LINCOLN COUNTY

(Special Correspondence.)—The Kalispell-Lincoln Gold Mining Co. has completed a 3-stamp mill on its property in the West Fisher district, 35 miles south of Libby, and it will be started at once. The company has a rich vein of gold-bearing quartz, a large part of which, according to the owners, will average \$100 per ton in gold.

Libby, September 16.

#### LEWIS AND CLARK COUNTY

At the State Fair being held at Helena during the present week, prizes will be given for the best collection of concentrator products, smelter products, and other displays. E. P. Mathewson, manager of the Washoe smelter at Anaconda, is chairman of the Mine Products Exhibit Committee.

#### SILVERBOW COUNTY

From the Badger State, a former Boston & Montana property, about 700 tons per day is being hoisted, but this could easily be increased if necessary. Five veins are being worked, including the Edith May and Jessie, of the North Butte. Ore sent to the smelter averages 4% copper and 5 oz. of silver per ton.

### NEVADA

#### ESMERALDA COUNTY

Work at the mines and mill of the Goldfield Consolidated continues on the usual lines, most of the ore coming from the Clermont and Mohawk; and high-grade ore being shipped from the deep workings of the Grizzly Bear to the smelter at Tooele, Utah. This ore now contributes largely to the company's output, and it is said that a large tonnage is available. The new station in the Grizzly Bear shaft, from which the drift is to be driven south into the property of the Atlanta company and to connect with the cross-cut from the Merger shaft within Atlanta ground, has been completed, and the drift will be started at once. This work will be of value to the three companies, as it will give good ventilation for their deep levels. The shares of the Goldfield Consolidated have been withdrawn from the New York Stock Exchange and are now being traded in on the Curb market. The main shaft at the Merger is now 1400 ft. deep, and at 1330 ft. a station is being cut out, from which a cross-cut will be driven to the Atlanta to connect with the drift from the Grizzly Bear. About 800 ft. north of the shaft, and in the ground formerly included in the Baby Florence No. 2 lease, the Florence Goldfield has stoped some rich ore. A raise from the cross-cut on the 350-ft. level has entered the shoot, and stoping is now in progress. Another raise has been started from this level, and for a width of two feet the ore averages \$300 per ton. Some good assays have been obtained from the 800-ft. level. The shaft is down 1245 ft., and work will soon be started on the 1200-ft. level. Ore is being sent to the Jumbo Extension mill, which has been shut down temporarily for repairs. Ore which averages \$50, containing tellurides, has been ex-

posed on the Diamondfield Black Butte, in the new workings of the Black Butte Leasing Co., a point southwest of the main shaft. A winze is being sunk on the vein, which shows 18 in. of rich ore at one end. A 40-hp. electric hoist is to be erected at the Goldfield Midway, and the shaft will be sunk to 500-ft. depth. Good assays have been obtained from an ore-shoot which has been opened on the north lode of the Vernal.

#### LYON COUNTY

The average shipments from the Nevada-Douglas for the past week were 350 tons of copper ore per day, the Ludwig providing 200 and the Douglas 150 tons. Gypsum is being sent out at a steady rate. The former mine is opening well, and the seventh level shows a good tonnage of 15% ore. The main incline is being sunk from 700 to 1000-ft. depth. The latter mine is being prospected by cross-cuts from adits. Diamond-drilling is to be started at the 700-ft. level of the Ludwig. The new ore-bin is well under way; and extra sidetracks and spurs are being laid down.

#### NYE COUNTY

During August the mines at Tonopah milled 41,586 tons of ore. For the week ended September 21 the production was 10,723 tons, with an estimated value of \$268,075. The Tonopah-Belmont made a net profit of \$151,074 for August, from 11,736 tons treated; and the West End made \$30,900 from 3650 tons. The mid-monthly clean-up of the Extension resulted in 36,524 oz. of bullion worth \$28,200. During the past week a fine orebody has been opened on the 1250-ft. level of the North Star. It was cut in the southeast cross-cut in andesite, near the Favorite claim of the Belmont company, and is 30 ft. wide, of quartz veins and country rock carrying low metal content, but 14 in. on the hanging wall showed silver and yellow pyrite of high assay value. Further driving opened 4 ft. of ore, and samples from across 14 in. and 24 in.

NEVADA HILLS MILL, FAIRVIEW, NEVADA.

gave 43 oz. of gold and 39 oz. of silver, and 53.1 oz. of gold and 58 oz. of silver, respectively. The four feet will average \$250 per ton. An employee at the Tonopah Mining Co.'s mill, at Millers, accidentally drank cyanide solution last week. The usual antidotes and stomach pump were promptly used, but failed to prevent his death.

The banks at Tonopah report the receipt of \$11,000 in bullion from the War Eagle and Associated mills at Manhattan, and \$1080 from various leases and \$700 in placer gold. On the 200-ft. level of the Big Four mine a width of 50 ft. of ore, worth \$25 per ton, has been opened. The raise from the 500 to the 400-ft. level is about completed. Assays have returned \$15 per ton from this work. The raise in the Kendall-Douglass lease of the Manhattan Consolidated is now up 40 ft., showing 5 ft. of rich sulphide ore, with a tendency to increase in width. All the ore hoisted is sent to the War Eagle mill and averages \$46 per ton. The Amalgamated has just completed a second crushing of 100 tons of ore averaging \$16 per ton, at the Associated mill. This ore comes from stopes above the 150-ft. level.

#### STOREY COUNTY

The new vertical centrifugal pump installed on the 2500-ft. level of the C. & C. shaft, is at work lifting water to the pumps at the 2310-ft. station. The two pumps here throw it to the Reidler pumps at 2000-ft. level, these elevating it to the Sutro tunnel drain. The water is being easily handled. The pressure water on the hydraulic elevator pumps has been turned off, they having been at work since 1899. The Ophir and Consolidated Virginia have made little headway during the past week on account of the changes in the pumps at the C. & C. shaft. The Consolidated Virginia has driven north and south on the 2300-ft. level through porphyry and quartz of low value. Good progress is being made with the Ophir cyanide plant.

At a meeting of the Comstock Pumping Association, held in San Francisco, it was decided to shut down the Ward shaft. This will mean the lifting of the pumps from the 2150-ft. station, and the rising of the water to its natural level, below the Sutro tunnel connection.

#### NEW MEXICO

##### LINCOLN COUNTY

The old White Oaks mining district, which is said to have produced gold valued at \$3,000,000, and is 150 miles north of El Paso, is likely to have a revival. The gold mines are just west of the town of White Oaks, and the coal mines are on the east side; and there is ample water for general purposes. The principal developed mines of the district are the Old Abe, South Homestake, North Homestake, Little Mack, Rita, Lady Godiva, Henry Clay, and a few in the prospecting stage. The first-named has a bullion production of \$1,000,000, and the second about \$900,000.

##### LUNA COUNTY

Prospects of an increased output from the mines in the Deming district are considered good, especially as the smelter at Deming will be opened very soon. The Chance mines will use the smelter mostly for its ores. The Helen group is shipping 300 tons of ore per month. The owners of the Othello and Desdemona have contracted to deliver 20,000 tons of lead and zinc ore.

#### UTAH

##### BEAVER COUNTY

So far during September the Majestic has sent out 27 cars of ore, and the total is expected to be 45, against 40 in August. None of this ore has come from below the adit level. It has been followed for 1500 to 1600 ft. and is 30 ft. wide in places. The ore is copper-bearing, with a high percentage of iron. Thirty men are employed underground.

##### JUAB COUNTY

It is not thought likely that the strike at Bingham will affect the mines in the Tintic district, unless the smelters are closed. When the mine-owners get together they will hear the committee selected by the miners to discuss the wage question. Development on the 500-ft. level at the Iron Blossom has opened a fair deposit of lead-silver ore, worth \$40 to \$50 per ton in the raise at this point. About 150 tons of ore per day is being shipped from the mine. Electric power is to be generally used at the Victoria mine. The Knight people have selected a site for their concentrating plant. During its past year the Black Jack development totaled 1218 ft., and ore shipments netted \$1954. The mine should yield a profit when the new mill is ready to deal with the low-grade ore. Good ore is being mined on the 700-ft. level of the Eagle & Blue Bell mine, and shipments may soon be increased to 12 cars per day. The May Day mine is shipping 10 cars of ore which will average about 30% zinc.

##### SALT LAKE COUNTY

Following are the wages paid at the Bingham mines, where the strike is still on: Machine men, \$3 per 8-hr. shift; machine helpers, \$2.75; hand and steel men, \$2.50 and \$2.75; timbermen and helpers, \$2.50; trammers, \$2.50;

horse and mule trammers, \$2.75; and 'nippers', \$2.50 per shift. Wages paid to employees on the surface are: Machinists on drills, \$4.80 per 10-hr. shift; first helpers, \$3.60; second helpers, \$2.50; drill sharpeners, \$3.50 per 9-hr. shift; blacksmiths, \$4; helpers, \$2.75; steam-shovel operators, \$190 per month for 10-hr. shift; crane-men, \$135; shovel firemen, \$3 per 10-hr. shift; carpenters, \$4.44; helpers, \$2.50; bank-men, \$3; powder-men, \$3.25; pipemen, \$2.50; engineers on switch engines, \$4.25; firemen on locomotives, \$3; brakemen, \$3.50; boilermakers, \$4; helpers, \$2.75; and compressors, \$4.50. An increase of 50c. per day for all classes of mine and mill labor is demanded.

Mr. Moyer, president of the Federation, said that "different strikes assume different attitudes, and it is not possible to forecast the future of the present strike. The Federation will do its utmost to preserve order and comply with the law. The officers of the Federation are ready to discuss the wage question. The strike is deplored, but it would have been obviated if the operators had treated with the unions." D. C. Jackling stated that "the whole trouble at the mines has been caused by a few men who have come into the district to make trouble. They are agitators pure and simple, and intended to make trouble when they came to the district. We have known what they were doing for some time; but there was no way of stepping in and stopping it without appearing arbitrary or unjust. They have raised all the trouble, mixing with the men for the single purpose of starting this strike. Now some must suffer, but these agitators will be the first to go. Notwithstanding the present high price of copper, the operators of the Utah Copper Co. have not yet fully reflected this condition, for it requires approximately four months from the time the ore is mined before the company can get its money for the product, and the present price of the metal has not been sustained for anything like such a period. No one can tell what the future action of the copper market will be, but we believe that it will be good, and therefore hope within a reasonable time to be able to readjust our scale, and offer increased wages to such classes of employees as are reasonably entitled to such increase." Regarding the concentrating plants and smelters likely to be affected, at Garfield there are about 2000 men at the former and 1200 at the latter. The International smelter employs 250, and there are 1100 employed at each plant at Murray and Midvale. The Ohio mill employs about 350, and other mills of the camp employ a total of 350 to 400 men. This makes about 6400 men employed in plants wholly or to a great extent dependent on the mines of Bingham for their employment. The Garfield smelter has a large tonnage of copper ore and concentrate on hand, but not enough to work full-handed for any length of time; the International smelter at Tooele has a good supply of lead ore on hand. The Midvale plant of the United States S. R. & M. Co. may be able to continue for a considerable time, but its Huff electrostatic zinc plant at Midvale will probably close, and the Murray smelter of A. S. & R. Co. should be able to work on indefinitely on lead-silver ores. It is stated that a great number of the foreigners employed in the mines are armed and have assumed a defiant attitude to mine officials and others, but there has been no serious trouble so far. It is quite possible, judging from the speeches of Federation leaders, that the trouble may extend to Butte in Montana and Ely in Nevada.

#### TOOELE COUNTY

Reports state that nearly \$1,000,000 worth of metal has accumulated at the International Smelting & Refining Co.'s plant at Tooele since the treatment of lead-silver ores was started last March. The new refinery at East Chicago, Indiana, is finished, and bullion is being sent from Tooele at a rate of 100 tons per day.

### CANADA

#### BRITISH COLUMBIA

(Special Correspondence.)—The Coronation Mines, Ltd.,

at Cadwallader creek, Lillooet, is doing a fair amount of development, and 12 miners are at work. The cross-cut on the 400-ft. level at the Little Joe claim cut the lode, which is from 18 to 24 in. wide, and the shoot has a length of 35 ft. A raise is being driven to No. 3 level, and gold is visible up the raise and along the drift. At the Countless claim, some 1200 ft. away from the former, a lode which outcropped on the surface 700 ft. west was cut 415 ft. from the portal of the cross-cut. This is 190 ft. from the surface, and shows free gold and pyrite over a width of four to five feet. Driving is under way for the Little Joe vein, which has been opened on the surface for over 600 ft., assaying \$18 per ton throughout. Victoria, September 18.

#### YUKON

The Yukon river is four feet lower at Dawson than at this time last year. About 3500 tons of freight has to leave White Horse for Dawson before the close of navigation. Of this amount, about 2000 tons is for dredges being constructed near the latter centre. Steamers have been delayed by sand and debris in the river, and the *Dawson Weekly News* of August 22 speaks plainly on the great gold output of the country, the necessity for keeping the river clear, the small Government appropriation for such work, and its effect on future work. The most prosperous mining creek is said to be the Sulphur, where there are a good number of open-cuts, self-dumpers, and windlass outfits. C. Nagin, who owns eight claims, recently cleaned up with a yield of \$5000, and E. Johnston has had several good runs, one yielding over \$2000. It is said that the White Pass & Yukon railway, which operates between Skagway and White Horse, 14 miles, has been sold to the Grand Trunk Pacific Railway Co., the actual transfer to be made on January 1, 1913.

### MEXICO

#### CHIHUAHUA

The revolution has interfered little with construction work of the Mexican Northern Power Co., and the plant should be completed by June 1913. This company has a paid-up capital of \$12,000,000, and \$10,000,000 bonds issued, and owns a concession to develop power on the Conchos river. The power-plant will cost \$8,000,000. The main dam at the Bogrulla is 900 ft. long, 230 ft. wide on the upstream side, and 200 ft. thick at the bottom. The present installation will develop 20,000 horse-power.

#### GUADALAJARA

Machine drills are working at the Tajo mine, in the San Sebastian district of this state, and development is quite satisfactory. In the deepest workings, the Porvenir adit, the Tajo vein is from four to six feet wide; and within 100 ft. in the west drift it is expected that an ore-shoot which yielded rich ore in past years will be cut. All work is done by adits on this property. A good deal of water flows from the Porvenir adit, and this will be used to provide power. G. J. Rockwell, of Denver, is in charge.

#### SONORA

(Special Correspondence.)—Notwithstanding the difficulties and adverse conditions caused by the Mexican revolution and Yaquis, the management of the Mina Mexico company, of Sonora, has been able to keep its plant at work and will make all efforts to continue operations. Comparative calm is prevailing at the mines, and no serious difficulties are anticipated. The old concentrator of the company is in course of reconstruction, and the remodeled plant will have a capacity of 100 tons per day. A rich orebody has been opened between the eighth and ninth levels, and development is being pushed vigorously. The shaft is nearly 1000 ft. deep. General indications are very promising for the future of the mine. The company has a large tonnage of rich ore and concentrate on hand and expects to blow in its 100-ton smelter shortly, and resume making shipments of concentrate and matte. Mina, September 8.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. B. LAMB is at Swastika.  
 C. W. MERRILL has gone East.  
 HARRY G. PEAKE is in Europe.  
 GELASIO CAETANI is in Arizona.  
 KARL EILERS is at the Fairmont.  
 A. J. EVELAND has been at Park City.  
 W. H. STORMS has gone to Bakersfield.  
 E. M. HAMILTON is at Cobalt, Ontario.  
 MARK B. KERR is here from Nevada City.  
 F. B. WEEKS was in San Francisco recently.  
 C. W. MORSE has gone to the Redding district.  
 HOWARD D. SMITH has returned from the East.  
 M. B. BELDEN has gone to Gilta, Siskiyou county.  
 LIONEL LINDSAY is visiting mills in the Southwest.  
 CLIFFORD G. DENNIS has returned to San Francisco.  
 CHARLES GUNDEROTH, of Utah, is at Miami, Arizona.  
 JOSEPH C. HOPPER is here on his return from Nevada.  
 R. HAY ANDERSON is returning to Mexico from London.  
 A. M. CHAMBERLIN has returned from Juneau to San Jose.  
 F. LYNWOOD GARRISON is expected in San Francisco during October.  
 K. C. STADTMUELLER is now with the Braden Copper Co. in Chile.  
 ALBERT BURCH has returned from Idaho and gone to Amador county.  
 FRED MILLER was in town during the week and has returned to Grass Valley.  
 HENRY R. PUTNAM has moved from Virginia City, Nevada, to San Francisco.  
 JOHN S. BUTLER is now with the Cia. Metalurgica Mexicana, at San Luis Potosi.  
 C. H. GREIME will leave Fairbanks, Alaska, at the end of September, for Seattle.  
 C. COLCOCK JONES was in San Francisco on his way to Los Angeles from Nevada.  
 J. PARKE CHANNING was here during the week and has returned to Salt Lake City.  
 F. H. PROBERT is at Patagonia, Arizona, and will return to Los Angeles during the week.  
 T. GEORGE MACKENZIE, who has been in Nova Scotia, is now at Parral, Chihuahua, Mexico.  
 F. L. SIZER is in Arizona, but expects to return to California about the first of the month.  
 E. P. CRAWFORD is at Berkeley on his return to Silver City, New Mexico, from a trip to Alaska.  
 W. RAY COX has been appointed mineral inspector for the General Land Office, with headquarters in San Francisco.

F. B. LAWSON, chairman of the Mountain Copper Co. passed through San Francisco on his way to Korea and the Far East.

BERNARD MACDONALD has been in Cobalt and New York, and has returned to Los Angeles, where he is staying during the trouble in Mexico.

## Obituary

JOHN ALEXANDER CHALMERS died on September 9 at his home in Bournemouth, England, after a long illness. He was formerly one of the engineers for the Consolidated Gold Fields of South Africa, and in collaboration with F. H. Hatch published 'The Gold Mines of the Rand.'

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice or mining, milling, and smelting.

**C**ONCRETE stringers are used underground in place of timber at the Ahmeek mine, Michigan.

**A**MSTERDAM has 70 factories for cutting and polishing diamonds, employing 1700 cutters and 4700 bur-nishers.

**A**NY machine, such as a concentrating-table, which re-jects certain material, is not fairly treated if that product is returned to it. If a middling product is rejected let another machine deal with it.

**S**ULPHUR production in Sicily for the year ended July 31, 1911, decreased from 397,000 to 392,000 tonnes; but exports increased from 297,000 to 446,000 tonnes, and visible stocks decreased to 535 tonnes.

**R**OLLS used for crushing ore are sometimes used in stages, and others are expected to reduce the ore in one operation. These machines are used at Broken Hill for crushing ore from rock-breakers before it is sent to shaking-screens and jigs.

**S**TEEL was probably first made in the United States in 1728, by Samuel Higley and Joseph Dewey, in Connecticut; crucible steel in 1832, at the works of W. & J. H. Garrard, at Cincinnati, Ohio; bessemer steel in 1864, by W. F. Durfee, at an experimental plant at Wyandotte, Michigan; and open-hearth steel in 1864, by the New Jersey Steel & Iron Co., at Trenton.

**G**ERMANY in the first six months of the current year produced 8,424,632 tons of pig iron, against 7,682,639 tons for this period of 1911. Domestic business is quieter than formerly, as nearly all consumers have covered their needs to the end of the year. Foreign trade continues to be lively, and is marked by increasing prices. The coal production for the first half of this year was 124,136,000 metric tons, and that of coke 13,755,000 tons. These totals are in advance of those for 1911.

**F**ULLER'S EARTH to the amount of 2563 tons, valued at \$29,137, was produced in Arkansas in 1910. The developed deposits of this state comprise an area of about three square miles, between Hot Springs and Benton, and were discovered in 1897. The earth is used for bleaching cottonseed oil, hog leaf lard, beef tallow, and stearine. The mined clay is stored for a time in sheds at the mines, hauled to a mill, and partly dried. A machine crushes it into about 1-in. pieces, when it is fed into iron cylinders and thoroughly dried by hot air or steam jacket. After this, the clay is pulverized and run through 'bolting reels,' as used in flour mills, filled into sacks holding 225 to 400 lb. each, and sent to market.

**C**HILE is devoting a good deal of attention to the development of coal mines. There is an increased consumption of Chilean coal every year, and the government uses it on its railroads when available. There are fairly large deposits, but more capital is required for their development. Some of the best coal is mined about three miles from Coronel bay, just south of Talcahuano. This mine has been worked for about 60 years. In 1911 the railway consumed 403,050 tons of Chilean against 116,209 tons of imported coal. Analyses of coal from 9 Chilean mines show the following: water, 0.98 to 4%; ash, 2 to 8%; sulphur, 0.21 to 4.9%; volatile matter, 32 to 43%; fixed carbon, 49 to 61%; and coke, 46 to 65 per cent.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### GAS LEASE—DILIGENCE REQUIRED

A gas lease providing for an annual royalty on each well contemplated that the land should be developed with due diligence, and on failure so to do the lessor was entitled to cancellation as to the undeveloped land.

Day v. Kansas City Pipe Line Co., (Kansas) 125 Pac., 43. July 6, 1912.

### OIL LEASE—ROYALTIES NOT PAYABLE AFTER SURRENDER

Under an oil lease providing for payment of royalties on oil produced and for penalty for failing to operate any well, the lessee was held liable for royalties only so long as the wells were operated, and after operation ceased, and until surrender of the lease, were liable only for the penalty for failure to operate. Mere failure to formally surrender the lease after the machinery had been removed did not entitle the lessor to further payment of rentals.

Dickey v. Coffeyville Vitrified Brick & Tile Co., (Kansas) 125 Pac., 74. July 6, 1912.

### MINING CONTRACT—RIGHT TO PURCHASE

Where the contract of purchase of mining property provided that title should not pass until the entire price was paid, and that the deed should be held in escrow, a fund being created consisting of a certain amount per month to pay the purchase price, and that failure to make three monthly payments or any yearly payment should render the contract void and forfeit to the vendor all payments made, the purchaser had a right to withdraw from the contract at any time without giving any reason therefor, and on so doing he could not be held for any further payments on the purchase price.

Richardson v. Dell, (Missouri) 149 Southwestern, 15. June 29, 1912.

### MINING PARTNERSHIP—DOES NOT EXIST, WHEN

Where several persons by an express or implied agreement organize a partnership to work a mine, and it appears that under the terms of such agreement the confidential relations of an ordinary partnership are to exist, and that the firm is not subject to intrusion of other partners at will, the fact that the business in which they are engaged is the working of a mine does not affect their relation or liability as general partners nor fix their relation as mining partners. Whether the relation is a general partnership or a mining partnership must be determined from the acts, intentions, and agreements of the parties as disclosed by the evidence.

Daily v. Fitzgerald, (New Mexico) 125 Pacific, 625. May 5, 1912.

### EXTRALATERAL RIGHT—BURDEN OF PROOF ON CLAIMANT

In an action of trespass for conversion of ore taken within the side-lines of plaintiff's claim, where the defense rests upon a claim that the ore was taken from a vein apexing within the limits of defendant's claim, the burden of proof is upon defendant to establish both the apex and continuity of the vein in question. For the exercise of an extralateral right, it must appear that the vein outside is identical with and a continuation of the one inside the claimant's boundaries. If the mineral disappears or the fissure with its walls of the same rock disappears, so that its identity can no longer be traced, the right to pursue it outside of the perpendicular line of claimant's survey is gone. To say, then, in this case, that the alleged apex on the Grand Trunk is that of the vein appearing on the Hecla, at a wholly unexplored distance of 550 ft., with a right angle distance of 300 ft. and an additional extended distance lengthwise of the claims 200 ft., is to base such conclusion upon mere speculation.

Collins v. Bailey, (Colorado) 125 Pac., 543. April 8, 1912. Rehearing denied, June 10, 1912.

## James Lewis & Son's Copper Report

During August standard copper prices have fluctuated to the extent of £2 15s. per ton, between £77 for cash on August 9 and £79 15s. on August 28, when £79 18s. 9d. was paid for late September delivery. The backwardation ruling for three months prompt has been converted into a contango, 10s. per ton being paid for carrying 500 tons. Sales amounted to about 46,000 tons, and closing prices are £79 6s. 3d. for cash and £79 15s. for three months. There has lately been an improved demand for refined copper, and considerable sales of electrolytic have been made by American refiners at 17<sup>3</sup>/<sub>4</sub>c. per pound.

American shipments from northern ports for the month are advised as 24,377 tons. European stocks have increased 458 tons, but the visible supply has decreased 242 tons. Imports have been 2825, and deliveries 7511 tons less than during the same period of last year. The total arrivals in England and France for August have been 23,025 and deliveries 21,685 tons of fine copper. Arrivals in England from Chile were 2311, and deliveries 2424 tons; and from other countries 13,655 and 12,612 tons respectively. Arrivals at Liverpool and Swansea from the United States have been 2293 tons of bars, and 995 tons of plate, equal to about 3279 tons fine; in London, 1055 tons; and France, 5331 tons. Chile charters for the month are advised as 3000 tons, including 2125 tons for the United States. Exports from the former country to August 31 were 25,215 tons, against 20,606 tons for the same period of 1911.

**GOLD AND COPPER IN TURKESTAN.**—In the eastern part of the Zaisan district many claims have been entered on areas containing gold. There are no enterprises with any considerable capital. According to information received from Turkestan some rich copper ore has been found in eastern Bokhara by a Russian officer, who for six years has been investigating this district. Analysis showed that the ore contained 24% copper. This interested Russian capitalists, and one of the Warsaw private banks is organizing a joint stock company to work these mines. Professor Norosivich, of Warsaw University, has been engaged by this bank to continue the investigation. Several English engineers from the Siberian Mining Syndicate have been searching for copper this year in Turkestan.

## Commercial Paragraphs

In constructing the new Union Stock Yards at Memphis, Tennessee, all the buildings, covering about 400,000 sq. ft. of land, were roofed with J-M Asbestos Roofing furnished by the H. W. JOHNS-MANVILLE Co. of New York.

The GENERAL ENGINEERING Co., Salt Lake City, Utah, announces the addition of Karl Bernson to its engineering staff. Mr. Bernson will act in the capacity of constructing engineer, taking active charge of all construction work. He has had a large and valuable experience in this class of work for the last fifteen years, having had charge of the construction of many of the largest sampling and concentrating mills, and other classes of mine and mill construction work in the western states.

Mr. Schwanhauser, chief engineer for the INTERNATIONAL STEAM PUMP Co., has returned from a three-months trip to Europe, visiting England, Germany, and Russia. While in London he closed a contract with S. Pierson & Son for the entire pumping equipment required for a new oil pipe-line now under construction in Mexico. The pumping engines will be furnished by the FRED M. PRESCOTT STEAM PUMP Co. of Milwaukee, Wisconsin, and the condensers and auxiliaries by Henry R. Worthington.

The prospector and small operator is coming into his own again. There is a strong demand for new properties, the Government officials are showing a disposition to co-operate, and everything points to a big resumption of prospecting and development this fall and early winter. A reflection of these conditions is shown in an alliance recently completed by the WAY'S POCKET SMELTER Co. The sales of this company have reached such a point that it has become advisable to separate the manufacturing and selling organizations. In the future, Way's Pocket Smelter Co. will devote its entire time to making smelters and in experimental work along new lines. The selling organization will be J. W. Swaren & Co., 112 Market street, San Francisco, California. In the future all orders for Way's smelters and supplies should be sent direct to J. W. Swaren & Co. In addition to the Way process, this new company will handle a complete line of machinery and supplies ordinarily used by prospectors and new properties. Mr. Swaren has been a prospector himself, and he fully appreciates the difficulties met in getting equipment and supplies while out in the hills or in the desert. His personal attention will be given to securing for the customers of this new firm the best materials on the market.

That the DODGE MANUFACTURING Co., Mishawaka, Indiana, does not confine all its efforts to the manufacture of stock goods in transmission machinery, was demonstrated September 13 when a split iron sheave, 288 in. (24) pitch diameter, with a 40-in. face width, was cast in the south foundry. It required about ten days for the foundrymen to shape up the big mould, about two hours to prepare for the pour, and a little over two minutes to pour the metal—approximately 53,000 pounds. The metal was distributed by means of immense ladles, through a runway over the mould. The sight was not only interesting but spectacular, and attracted a large number of outsiders. The wheel when finished will weigh about 45,000 lb. It was made for the Anaconda Copper Mining Co., Anaconda, Montana, for use on the shaft of a 46 by 60 duplex blowing engine. It is grooved for twenty 1<sup>3</sup>/<sub>8</sub>-in. Dodge 'Firmus' manila ropes, has a 16-in. bore, and will be driven by another sheave 48 in. diameter on a 750-hp. motor at 59 r.p.m. The large wheel was cast in two sections and will be shipped in that condition. After it leaves the machine-shops at the mines the halves will be fastened together permanently not only by bolts through rim lugs. Several years ago the company made a large wheel for the Kokomo (Indiana) Steel & Wire Co. This was also 24-ft. diameter, 7<sup>1</sup>/<sub>2</sub>-in. face width, and weighed 80 tons. It was of four-piece construction, consisting of two split pulleys bolted together by internal rim flanges.

## EDITORIAL

**P**RESIDENCY of the Ananias Club will doubtless be unanimously awarded to W. R. Hearst, in the light of recent disclosures.

**I**NTEREST was marked in the National Irrigation Congress, held at Salt Lake City during the past week, and well known speakers addressed the gathering.

**M**INERS at the Nevada Consolidated have struck in sympathy with the men at Bingham, and the 20-cent copper predicted by our New York correspondent becomes more than a possibility.

**A**RIZONA is surprised to find that its workmen's compensation law, recently enacted, does not compensate. Somebody slipped into it this proviso: "it shall be lawful, however, for the employer or workman to disaffirm an employment under the provisions of this act by written contract between them or by written notice of one to, and served upon, the other to that effect before the day of the accident."

**F**OREIGN capital has played an important part in the development of industry in Brazil and is showing a remarkable rate of growth. The capital of the Brazilian companies authorized last year amounted to 13,597 contos of reis (a conto of reis equals \$546,000), or an increase of 103 per cent over the preceding year, while the capital of foreign companies amounted to 311,518 contos, or an increase of 232 per cent during the year. Investors are evidently not slow to recognize the possibilities of the Brazilian field, and the Rio Janeiro loan of \$15,000,000 at 5 per cent, which is soon to be placed in London, is likely to be well received.

**A**NNOUNCEMENT has been made of the sixteenth annual convention of the California Miners' Association, to be held in San Francisco on December 9, 10, and 11 of this year. The Association is planning to assist in securing for the Panama-Pacific International Exposition a mineral exhibit which will surpass any other in this country. The effort is an admirable one, and the Association has been so effective in the past that success may be anticipated. Success can only come, however, through the participation of all engaged in the mining industry in California, and it is to be hoped that the response will be spontaneous and generous.

**L**IGHT upon present problems can often be best obtained by a study of that which is old, while the consideration of the growth of present ideas is always helpful in formulating more advanced concepts. We are glad, therefore, to present this week the interesting summary of the theories of ore deposition prior to the seventeenth century, which Mr. and Mrs. Hoover have prepared as a footnote to the chapter in their translation of Agricola's 'De Re Metallica,' which treats of ore deposits. The Saxon physician, George Bauer, was the first to reduce the vague medieval notions concerning mineralogy and metallurgy to a scientific basis, and his writings are of the most intense interest to students

of geology and mining. They offer almost insuperable difficulty to the ordinary Latin scholar, for he employs several hundred Latin technical terms which are not defined in a glossary, and of which the meaning can only be perceived by painstaking comparison and study. No less than seven other translators have carried the work part way to completion, only to abandon it in despair. All those engaged in mining will be correspondingly grateful to Mr. and Mrs. Hoover for their patience and persistence in rendering available to all this mine of interest and information.

**A**UTHORS too frequently neglect to remember the reader, and the announcement sent out by Mr. Alfred C. Lane regarding his elaborate two-volume study of the Keweenaw series, recently published by the Michigan Geological Survey, is as unusual as it is refreshing in its frankness. Mr. Lane says that the report "is so largely a mass of detail that, in view of the extreme unlikelihood that anyone but the author will ever read it through, I have thought best to reprint and distribute a few pages only, which may be of general interest." Mr. Lane's studies have been of the greatest interest to geologists, but especially we beg to compliment him upon the grateful appreciation his consideration for the overworked reader is sure to bring.

**B**OSTON copper circles have suffered a severe shock from the failure of the house of Stephen R. Dow & Company, members of the Boston stock exchange and widely known by reason of the firm's connection with some of the recently developed properties in Michigan—Franklin, North Lake, and Indiana. North Lake and Indiana were each sensational prospects in 1910, when the diamond-drill cores were thought to foreshadow the development of another Calumet & Hecla. The treasuries of the various copper companies under the Dow management held a total of some \$300,000, all of which was borrowed by the failed firm. The whole matter is material for a sermon on the benefits to be derived from publicity in mining affairs. Compulsory independent periodical auditing and the publication of monthly reports showing mining progress and operating costs are two forward steps that mining shareholders should demand. A comparison of the methods prevailing in this country with those followed by the companies organized under the English law furnishes a large part of the reason for the different attitude prevailing in the two countries. In this country the idea that the shareholder is entitled to any specific information regarding the work under way seems not to prevail. In England the information is published and sent to the stockholders, and sudden unfavorable disclosures are, in a measure, except in case of actual fraud or misrepresentation, prevented. In the present instance there was on the part of the company no attempt to conceal the facts. It was simply a case of no sentinel on duty. Mine work is from some points of view more important than financial management. One of the most important and interesting gold producers in the world, Goldfield Consolidated, has been the cause of much bitter complaint on the part of Eastern buyers because the holders of the shares have been without authentic information on which to base any estimate of the life of the property. The energy and ability of the management has been conceded, but mining properties are owned by the shareholders, who are entitled to all of the information there is, good, bad, and indifferent, as a matter of absolute right. Nothing would be more effective to establish mining on its proper footing and to create a growing and a satisfied public following than the enactment and enforcement of a set of regulations that would place both financial and physical details before the stockholders and the public.

## What Are Profits in Mining?

Fundamental concepts are seldom clearly grasped by the general public, and, if the simile be permitted, the average man knows how fast he is progressing, but rarely has any clear ideas as to whether he is headed in the right direction. To our discussion columns Mr. J. R. Finlay, who speaks with authority, contributes an interesting and suggestive letter in regard to profits in mining. The matter is one which has been too little considered, and we hope our readers will join in the discussion. Reserving our remarks until later, it will be worth while to call attention to the confusion of thought which has existed even in great minds. In his 'Wealth of Nations' Adam Smith has the following to say regarding mining:

"Of all those expensive and uncertain projects which bring bankruptcy upon the greater part of the people who engage in them, there is none, perhaps, more perfectly ruinous than the search after new silver and gold mines. It is perhaps the most disadvantageous lottery in the world, or the one which the gain of those who draw the prizes bears the least proportion of the loss of those who draw the blanks; for though the prizes are few, and the blanks many, the common price of a ticket is the whole fortune of a very rich man.

"Projects of mining, instead of replacing the capital employed in them, together with the ordinary profits of stock, commonly absorb both capital and profit. They are the projects, therefore, to which, of all others, a prudent lawgiver, who desires to increase the capital of his nation, would least choose to give an extraordinary encouragement, or to turn toward them a greater share of that capital than what would go to them of its own accord. Such is the absurd confidence which almost all men have in their own good fortune, that wherever there is the least probability of success, too great a share of it is apt to go to them of its own accord.

"But though the judgment of sober reason and experience concerning such projects has always been extremely unfavorable, that of human avidity has commonly been quite otherwise. The same passion which has suggested to so many people the absurd idea of the philosopher's stone has suggested to others the equally absurd one of immense rich mines of gold and silver.

"The dream of Sir Walter Raleigh concerning the golden city of El Dorado may satisfy us that even wise men are not always exempt from such strange delusions. More than a hundred years after the death of that great man, the Jesuit Gumila was still convinced of the reality of that wonderful country, and expressed with great warmth, and, I dare say, with great sincerity, how happy he should be to carry the light of the Gospel to a people who could so well reward the pious labors of their missionary."

Mining is often grouped with agriculture as the two industries which are creative of wealth, but the analogy is not a close one, the products of agriculture being directly consumed to furnish vital energy, while metals and minerals serve as aids to human industry. It is evident that agriculturists produce more food than they eat; it is not so evident that mining operations produce more wealth than they consume, for the compilation of a balance-sheet offers insuperable difficulties. The catch phrase is often heard, "more money is lost in mining than is made," which recalls a casual remark of a friend, a professor of political economy, "more money is lost in gambling than is won." If the farmer's crop return him less wheat than he sowed, he does not despair, for the next may be a good year and recompense him a hundred-fold. But if the mine's final yield is less in value than the expenditures in developing

and operating it, there is no profitable future to hope for. Is the profit real, or is it a phantom one? Why should anyone engage in the nefarious and "perfectly ruinous" search after new silver and gold mines?"

### The Problem of Fines

The treatment of finely divided material offers one of the greatest problems in metallurgical work. In ore dressing the smallest particles offer the greatest resistance to separatory processes, and in cyaniding the fine material for a long time, and even at present to a certain extent presents great difficulties in filtering and washing, while the colloids, those curious denizens of the border land between solid and liquid, have only recently been rendered amenable to treatment. In the smelting of iron and copper ores the use of large quantities of finely divided ore in the blast-furnace is a vexing problem to the metallurgist, a problem that persists to the end of metallurgical work, for the gases escaping from the stack carry with them fine solid particles that are both a source of loss to the smelter and of annoyance to its neighbors. On another page, Mr. Anton Eilers describes the use of the bag-house to remove fine solid particles from the escaping fume of lead smelters.

It is, however, to the handling of fine ore in smelting operations that we propose to confine ourselves, referring more particularly to the smelting of copper ores. Fines have always been a problem in this work, and even in the days of the heap-roasting of lump ores the disposal of the small amount of fine ore unavoidably produced in mining was a source of worry to the metallurgist. The early conditions now seem almost like an iridescent dream to the many operators who are compelled to handle concentrate alone, or with but a small proportion of lump ore. A large and increasing part of the output of copper is derived from finely disseminated low-grade sulphide ore which must first be subjected to mechanical concentration. Smelting concentrate, practically all smaller than  $\frac{1}{8}$  inch in diameter, and unmixed with lump ore, is an irritating problem. The Gordian knot can be quite simply cut by roasting the concentrate and smelting the calcine in reverberatory furnaces, but only at a high working cost. At a plant where coke costs \$10 per ton the sulphur in concentrate containing 50 per cent of pyrite is worth \$2.50 per ton as a source of heat in smelting operations, and to be obliged to roast it off at a cost of about 50 cents per ton is heart-rending. In addition, the smelting cost per ton is higher in reverberatory work, though recent advances in the use of liquid fuel has increased the tonnage smelted and lowered costs. Progress in the use of gaseous fuel is of the negative order, for at the one copper smelter where it has been in use, the Great Falls plant of the Anaconda Copper Mining Company, the use of gas producers will be abandoned in the new construction now under way, and grate firing substituted. In this case the high ash of the coal used gave trouble in the regenerative checkerwork, another instance of the fines problem.

For handling fine ore in smelting, a great variety of ingenious methods have been devised. Since sulphides are readily fusible it would perhaps seem simplest to melt them and allow them to consolidate on cooling. Like most simple suggestions, this is impracticable. Melting and cooling sulphides, while retaining their sulphur content, offers annoying mechanical problems and can only be done at a prohibitive cost. But to fuse the fine ore to such a degree that it coheres sufficiently to act like lump ore in the blast-furnace is more practicable, and is the line upon which the most recent and satisfactory progress has been made. In this work the problems are essentially analogous to those of coke-making. The mixture must be fused sufficiently to

make it cohere strongly enough so that it will not break up too much in handling nor crush under the weight of the burden in the blast-furnace. The resulting product should be porous in order to aid the penetration of the blast and to facilitate the reactions of smelting. The complexity of this single group of problems is too little realized. In coking, the components present vary in degree but not in kind, yet the most careful study of the mixture of coal and water fed to the ovens is required to procure a satisfactory product. In smelting, the components vary in kind as well as in degree, and the amount of study of each particular case thus required is correspondingly greater. It is not remarkable, therefore, that the attempt to use such methods has often been abandoned after a short period of unsuccessful experimentation. Smelting differs radically from other kinds of chemical engineering work in that it is essentially variable in its character. A variety of different products must be utilized, and their relative proportions vary from week to week because of conditions not under the metallurgists' control, and methods which would be adequate to solve a constant problem may fail utterly before a variable one. This is the fundamental problem in the use of agglomerative methods for handling fines, and both in sintering on grates and in pots the securing of a mixture which shall be uniform throughout, both in a single operation and during the day's work, is one of the criteria of success.

In the treatment of lead ores agglomeration by fusing in pots and on grates is carried out with marked success and has reached a higher stage of development than the agglomeration of copper ores. The conditions to be met differ with the two methods. With lead ores the endeavor is to eliminate sulphur, and the ore is commonly subjected to a light roast before sintering in pots, while with copper ores the sulphur should be preserved to as large an extent as possible. The hot zone of oxidation that passes through the mass to be sintered is easily controlled if a relatively small quantity of sulphur is present and can be allowed to oxidize nearly completely, but is rebellious where there is present a large percentage of sulphur, only a part of which can be allowed to oxidize. But this problem is essentially similar to that in coking, where excessive fusing is checked by the addition of a suitable amount of moisture, and it may eventually prove that the sintering of fine copper sulphides on grates is more easy to perform than has been supposed. The sintering of flue-dust, with or without a small quantity of coke dust, is now successfully done both at the Pittsmonth and Mason Valley copper smelters, and the sintering of fine ore may follow as the next step in development.

Disposal of fine sulphides by adding them to the converter charge has often been proposed, but has not attained any marked success. Aside from the difficulties it gives rise to, it is evident that it cannot offer any universal solution of the problem, since the larger proportion of the ore must be otherwise treated in order to produce the matte for converting. Briquetting in its various forms is as old as the industry itself, and has been a continuous source of vexation. Under certain conditions it may be applied with marked success, as at Anaconda, but the hope of escape from its annoyances is a constant lure to the metallurgist, and there is little hope of satisfactory progress in the improvement of briquetting. Special methods serve to meet special conditions, especially where labor is cheap; thus flue-dust is mixed with converter slag at Cananea, and the nodulizing method recently described in these columns is satisfactory at Shisaka, in Japan, but everywhere the hope of devising a more satisfactory method is a potent force making for progress.

# Theories of Ore Deposition Prior to the Seventeenth Century

By H. C. and L. H. HOOVER

\*Prior to Agricola there were three schools of explanation of the phenomena of ore deposits, the orthodox followers of the book of Genesis, the Greek Philosophers, and the Alchemists. The geology of Genesis—contemporaneous formation of everything—needs no comment other than that for anyone to have proposed an alternative to the dogma of the orthodox during the Middle Ages required much independence of mind. Of the Greek views—which are meagre enough—that of the Peripatetics greatly dominated thought on natural phenomena down to the seventeenth century. Aristotle's views may be summarized: The elements are earth, water, air, and fire; they are transmutable and never found pure, and are endowed with certain fundamental properties which act as an 'efficient' force upon the material cause—the elements. These properties are dryness and dampness and heat and cold, the latter being active, the former passive. Further, the elements are possessed of weight and lightness, for instance, earth is absolutely heavy, fire absolutely light. The active and passive properties exist in binary combinations, one of which is characteristic, that is, 'earth' is cold and dry, water damp and cold, fire hot and dry, air hot and wet; transmutation took place, for example, by removing the cold from water, when air resulted (really steam), and by removing the dampness from water, when 'earth' resulted (really any dissolved substance). The transmutation of the elements in the earth (meaning the globe) produces two 'exhalations,' the one fiery (probably meaning gases), the other damp (probably meaning steam). The former produces stones, the latter the metals. Theophrastus (On Stones, i to vii) elaborates the views of Aristotle on the origin of stones, metals, etc.: "Of things formed in the earth some have their origin from water, others from earth. Water is the basis of metals, silver, gold, and the rest; 'earth' of stones, as well the more precious as the common. . . All these are formed by solidification of matter pure and equal in its constituent parts, which has been brought together in that state by mere afflux or by means of some kind of percolation, or separated. . . . The solidification is in some of these substances due to heat and in others to cold." (Based on Hill's Trans., pp. 3-11). That is, the metals inasmuch as they become liquid when heated must be in a large part water, and, like water, they solidify with cold. Therefore, the 'metals are cold and damp.' Stones, on the other hand, solidify with heat and do not liquefy, therefore, they are 'dry and hot' and partake largely of 'earth.' This 'earth' was something indefinite, but purer and more pristine than common clay. In discussing the ancient beliefs with regard to the origin of deposits, we must not overlook the import of the use of the word 'vein' (*vena*) by various ancient authors including Pliny (xxxiii, 21), although he offers no explanation of the term.

During the Middle Ages there arose the horde of Alchemists and Astrologers, a review of the development of whose muddled views is but barren reading. They in the main held more or less to the Peripatetic view, with additions of their own. Geber (thirteenth (?) century) propounded the conception that all metals are composed of varying proportions of 'spiritual' sulphur and quicksilver, and to these Albertus Magnus added salt. The Astrologers contributed the idea that the immediate cause of the metals were the various planets. The only work devoted to description of ore deposits prior to Agricola was the *Bergbüchlein* (about 1500), and this little book exhibits the absolute apogee of muddled thought derived from the Peripa-

tetics, the Alchemists, and the Astrologers. We believe it is of interest to reproduce the following statement, if for no other reason than to indicate the great advance in thought shown by Agricola.

"The first chapter or first part; on the common origin of ore, whether silver, gold, tin, copper, iron, or lead ore, in which they all appear together, and are called by the common name of metallic ore. It must be noticed that for the washing or smelting of metallic ore, there must be one who works and the thing that is worked upon, or the material upon which the work is expended. The general worker (efficient force) on the ore and on all things that are born, is the heavens, its movement, its light and influences, as the philosophers say. The influence of the heavens is multiplied by the movement of the firmaments and the movements of the seven planets. Therefore, every metallic ore receives a special influence from its own particular planet, due to the properties of the planet and of the ore, also due to properties of heat, cold, dampness, and dryness. Thus gold is of the Sun or its influence, silver of the Moon, tin of Jupiter, copper of Venus, iron of Mars, lead of Saturn, and quicksilver of Mercury. Therefore, metals are often called by these names by hermits and other philosophers. Thus gold is called the Sun, in Latin *Sol*, silver is called the Moon, in Latin *Luna*, as is clearly stated in the special chapters on each metal. Thus briefly have we spoken of the 'common worker' of metal and ore. But the thing worked upon, or the common material of all metals, according to the opinion of the learned, is sulphur and quicksilver, which through the movement and influence of the heavens must have become united and hardened into one metallic body or one ore. Certain others hold that through the movement and the influence of the heavens, vapors or *braden*, called mineral exhalations, are drawn up from depths of the earth, from sulphur and quicksilver, and the rising fumes pass into the veins and stringers and are united through the effect of the planets and made into ore. Certain others hold that metal is not formed from quicksilver, because in many places metallic ore is found and no quicksilver. But instead of quicksilver they maintain a damp and cold and slimy material is set up on all sulphur which is drawn out from the earth, like your perspiration, and from that mixed with sulphur all metals are formed. Now each of these opinions is correct according to a good understanding and right interpretation; the ore or metal is formed from the fattiness of the earth as the material of the first degree (primary element), also the vapors or *braden* on the one part and the materials on the other part, both of which are called quicksilver. Likewise in the mingling or union of the quicksilver and the sulphur in the ore, the sulphur is counted the male and the quicksilver the female, as in the bearing or conception of a child. Also the sulphur is a special worker in ore or metal.

"The second chapter or part; deals with the general capacity of the mountain. Although the influence of the heavens and the fitness of the material are necessary to the formation of ore or metal, yet these are not enough thereto. But there must be adaptability of the natural vessel in which the ore is formed, such as the veins, namely, *steinendegange*, *flachgange*, *schargange*, *creutzgange*, or as these may be termed in provincial names. Also the mineral force must have easy access to the natural vessel, such as through the *kluffte* (stringers), namely, *hengklufft*, *queckkluffte*, *flachekluffte*, *creutzklufft*, and other occasional *flotzwerk*, according to their various local names. Also there must be a suitable place in the mountain which the veins and stringers can traverse."

AGRICOLA'S VIEWS ON THE ORIGIN OF ORE DEPOSITS.—

\*A footnote to Book III of 'Agricola's de Re Metallica,' translated and annotated by H. C. and L. H. Hoover. *The Mining Magazine*, London, 1912.

Agricola rejected absolutely the Biblical view which, he says, was the opinion of the vulgar; further, he repudiates the Alchemistic and Astrological views with great vigor. There can be no doubt, however, that he was greatly influenced by the Peripatetic philosophy. He accepted absolutely the four elements—earth, fire, water, and air, and their 'binary' properties, and the theory that every substance had a material cause operated upon by an efficient force. Beyond this he did not go, and a large portion of *De Ortu et Causis* is devoted to disproof of the origin of metals and stones from the Peripatetic 'exhalations.'

No one should conclude that Agricola's theories are set out with the clarity of Darwin or Lyell. However, the matter is of such importance in the history of the theory of ore deposits, and has been either so ignored or so colored by the preconceptions of narrators, that we consider it justifiable to devote space necessary to a reproduction of his own statements from *De Ortu et Causis* and other works. Before doing so we believe it will be of service to readers to summarize these views, and in giving quotations from the author's other works, to group them under special headings, following the outline of his theory given below. His theory was:

1. Openings in the earth (*canales*) were formed by the erosion of subterranean waters.

A, B, C, VEIN. D, E, F, SEAMS IN THE ROCKS.

2. These ground-waters were due (a) to the infiltration of the surface waters, rain, river, and sea water; (b) to the condensation of steam (*halitus*) arising from the penetration of the surface waters to greater depths—the production of this *halitus* being due to subterranean heat, which, in his view, was in turn due in the main to burning bitumen (a comprehensive genera which embraced coal).

3. The filling of these *canales* is composed of 'earth,' 'solidified juices,' 'stone,' metals, and 'compounds,' all deposited from water and 'juices' circulating in the *canales*.

'Earth' comprises clay, mud, ochre, marl, and 'peculiar earths' generally. The origin of these 'earths' was from rocks, due to erosion, transportation, and deposition by water. 'Solidified juices' (*succi concreti*) comprised salt, soda, vitriol, bitumen, etc., being generally those substances which he conceived were soluble in and deposited from water. 'Stones' comprised precious, semi-precious, and unusual stones, such as quartz, fluorspar, etc., as distinguished from country rock; the origin of these he attributed in minor proportion to transportation of fragments of rock, but in the main to deposits from ordinary mineral juice and from 'stone juice' (*succus lapidescens*). Metals comprised the seven traditional metals; the 'compounds' comprised the metallic minerals; and both were due to deposition from juices, the compounds being due to a mixture of juices. The 'juices' play the most important part in Agricola's theory. Each substance had its own particular juice, and in his theory every substance had a material and an efficient cause, the first being the juice, the second being heat or cold. Owing to the latter the juices fell into two categories—those solidified by heat (that is, by evaporation,

such as salt), and those solidified by cold (that is, because metals melt and flow by heat, therefore their solidification was due to cold, and the juice underwent similar treatment). As to the origin of these juices, some were generated by the solution of their own particular substance, but in the main their origin was due to the combination of 'dry things,' such as 'earth,' with water, the mixture being heated, and the resultant metals depended upon the proportions of 'earth' and water. In some cases we have been inclined to translate *succus* (juice) as 'solution,' but in other cases it embraced substances to which this would not apply, and we feared implying in the text a chemical understanding not warranted prior to the atomic theory. In order to distinguish between earths (clays, etc.), the Peripatetic 'earth' (a pure element) and the earth (the globe) we have given the two former in quotation marks. There is no doubt some confusion between earth (clays, etc.) and the Peripatetic 'earth,' as the latter was a pure substance not found in its pristine form in nature; it is, however, difficult to distinguish between the two.

ORIGIN OF CANALES (*De Ortu*, p. 35).—"I now come to the *canales* in the earth. These are veins, veinlets, and what are called 'seams in the rocks.' These serve as vessels or receptacles for the material from which minerals (*res*

A, B, C, VEIN. D, E, F, SEAMS IN THE ROCKS.

*fossiles*) are formed. The term *vena* is most frequently given to what is contained in the *canales*, but likewise the same name is applied to the *canales* themselves. The term vein is borrowed from that used for animals, for just as their veins are distributed through all parts of the body, and just as by means of the veins blood is diffused from the liver throughout the whole body, so also the veins traverse the whole globe, and more particularly mountainous districts; and water runs and flows through them. With regard to veinlets or stringers and 'seams in the rocks,' which are the thinnest stringers, the following is the mode of arrangement. Veins in the earth, just like the veins of an animal, have certain veinlets of their own, but in a contrary way. For the larger veins of animals pour blood into the veinlets, while in the earth the humors are usually poured from the veinlets into the larger veins, and rarely flow from the larger into the smaller ones. As for the seams in the rocks (*commissurae saxorum*) we consider that they are produced by two methods: by the first, which is peculiar to themselves, they are formed at the same time as the rocks, for the heat bakes the refractory material into stone, and the non-refractory material similarly heated exhales its humors and is made into 'earth,' generally friable. The other method is common also to veins and veinlets, when water is collected into one place it softens the rock by its liquid nature, and by its weight and pressure breaks and divides it. Now, if the rock is hard, it makes seams in the rocks and veinlets, and if it is not too hard it makes veins. However, if the rocks are not hard, seams and veinlets are created as well as veins. If these do not carry a very large quantity of water, or if

they are pressed by a great volume of it, they soon discharge themselves into the nearest veins. The following appears to be the reason why some veinlets or stringers and veins are *profundae* and others *dilatatae*. The force of the water crushes and splits the brittle rocks; and when they are broken and split, it forces its way through them and passes on, at one time in a downward direction, making small and large *venae profundae*, at another time in a lateral direction, in which way *venae dilatatae* are formed. Now since in each class there are found some which are straight, some inclined, and some crooked, it should be explained that the water makes the *vena profunda* straight when it runs straight downward, inclined when it runs in an inclined direction; and that it makes a *vena dilatata* straight when it runs horizontally to the right or left, and in a similar way inclined when it runs in a sloping direction. Stringers and large veins of the *profunda* sort, extending for considerable lengths, become crooked from two causes. In one case when narrow veins are intersected by wide ones, then the latter bend or drag the former a little. In the other case, when the water runs against very hard rock, being unable to break through, it goes around the nearest way, and the stringers and veins are formed bent and crooked. This last is also the reason we sometimes see crooked small and large *venae dilatatae*, not unlike the gentle rise and fall of flowing water. Next, *venae profundae* are wide, either because of abundant water or because the rock is fragile. On the other hand, they are narrow, either because but little water flows and trickles through them, or because the rock is very hard. The *venae dilatatae*, too, for the same reason, are either thin or thick. There are other differences, too, in stringers and veins, which I will explain in my work, *De Re Metallica*. . . . There is also a third kind of vein which, as it cannot be described as a wide *vena profunda*, nor as a thick *vena dilatata*, we will call a *vena cumulata*. These are nothing else than places where some species of mineral is accumulated; sometimes exceeding in depth and also in length and breadth 600 ft.; sometimes, or rather generally, not so deep nor so long, nor so wide. These are created when water has broken away the rock for such a length, breadth, and thickness, and has flung aside and ejected the stones and sand from the great cavern which is thus made; and afterward when the mouth is obstructed and closed up, the whole cavern is filled with material from which there is in time produced some one or more minerals. Now I have stated when discoursing on the origin of subterranean humors, that water erodes away substances inside the earth, just as it does those on the surface, and least of all does it shun minerals; for which reason we may daily see veinlets and veins sometimes filled with air and water, but void and empty of mining products, and sometimes full of these same materials. Even those which are empty of minerals become finally obstructed, and when the rock is broken through at some other point the water gushes out. It is certain that old springs are closed up in some way and new ones opened in others. In the same manner, but much more easily and quickly than in the solid rock, water produces stringers and veins in surface material, whether it be in plains, hills, or mountains. Of this kind are the stringers in the banks of rivers which produce gold, and the veins which produce peculiar earth. So in this manner in the earth are made *canales* which bear minerals."

ORIGIN OF GROUND-WATERS (*De Ortu*, p. 5).—" . . . Besides rain there is another kind of water by which the interior of the earth is soaked, so that being heated it can continually give off *halitus*, from which arises a great and abundant force of waters." In description of the *modus operandi* of *halitus*, he says (p. 6); " . . . *Halitus* rises to the upper parts of the *canales*, where the congealing cold turns it into water, which by its gravity and weight again runs down to the lowest parts and increases the flow of water if there is any. If any finds its way through a *canales dilatata* the same thing happens, but it is carried a long way from its place of origin. The first phase of distillation teaches us how this water is produced, for when

that which is put into the ampulla is warmed it evaporates (*expirare*), and this *halitus* rising into the operculum is converted by cold water, which drips through the spout. In this way water is being continually created underground." (*De Ortu*, p. 7): "And so we know from all this that of the waters which are under the earth, some are collected from rain, some arise from *halitus* (steam), some from river water, some from sea water; and we know that the *halitus* is produced within the earth partly from rain water, partly from river water, and partly from sea water." It would require too much space to set out Agricola's views upon the origin of subterranean heat which produced this steam. It is an involved theory embracing clashing winds, burning bitumen, coal, etc., and is fully set out in the latter part of Book II, *De Ortu et Causis*.

ORIGIN OF GANGUE MINERALS.—It is necessary to bear in mind that Agricola divided minerals (*res fossiles*—'things dug up') into 'earths,' 'solidified juices,' 'stones,' 'metals,' and 'compounds'; and, further, to bear in mind that in his conception of the origin of things generally, he was a disciple of the Peripatetic logic of a 'material substance' and an 'efficient force,' as mentioned above.

As to the origin of 'earths,' he says (*De Ortu*, p. 38): "Pure and simple 'earth' originates in the *canales* in the following way: rain water, which is absorbed by the surface of the earth, first of all penetrates and passes into the inner parts of the earth and mixes with it; next, it is collected from all sides into stringers and veins, where it, and sometimes water of other origin, erodes the 'earth' away—a great quantity of it if the stringers and veins are in 'earth,' a small quantity if they are in rock. The softer the rock, the more water wears away particles by its continual movement. To this class of rock belongs limestone, from which we see chalk, clay, and marl, and other unctuous 'earths' made; also sandstone, from which are made those barren 'earths' which we may see in ravines and on bare rocks. For the rain softens limestone or sandstone and carries particles away with it, and the sediment collects together and forms mud, which afterward solidifies into some kind of 'earth.' In a similar way under the ground the power of water softens the rock and dissolves the coarser fragments of stone. This is clearly shown by the following circumstance, that frequently the powdered rock or marble is found in a soft state and as if partly dissolved. Now, the water carries this mixture into the course of some underground *canalis*, or dragging it into narrow places, filters away. And in each case the water flows away and a pure and uniform material is left from which 'earth' is made. . . . Particles of rock, however, are only by force of long time so softened by water as to become similar to particles of 'earth.' It is possible to see 'earth' being made in this way in underground *canales* in the earth, when drifts or tunnels are driven into the mountains, or when shafts are sunk, for then the *canales* are laid bare; also it can be seen above ground in ravines, as I have said, or otherwise disclosed. For in both cases it is clear to the eye that they are made out of the 'earth' or rocks, which are often of the same color. And in just the same way they are made in the springs which the veins discharge. Since all those things which we see with our eyes and which are perceived with our senses, are more clearly understood than if they were learnt by means of reasoning, we deem it sufficient to explain by this argument our view of the origin of 'earth.' In the manner which I have described, 'earths' originate in veins and veinlets, seams in the rocks, springs, ravines, and other openings, therefore all 'earths' are made in this way. As to those that are found in underground *canales* which do not appear to have been derived from the earth or rock adjoining, these have undoubtedly been carried by the water for a greater distance from their place of origin; which may be made clear to anyone who seeks their source."

On the origin of solidified juices, he states (*De Ortu*, p. 43): "I will now speak of solidified juices (*succi concreti*). I give this name to those minerals which are without difficulty resolved into liquids (*humore*). Some stones

and metals, even though they are themselves composed of juices, have been compressed so solidly by the cold that they can only be dissolved with difficulty or not at all. . . . For juices, as I said above, are either made when dry substances immersed in moisture are cooked by heat, or else they are made when water flows over 'earth,' or when the surrounding moisture corrodes metallic material; or else they are forced out of the ground by the power of heat alone. Therefore, solidified juices originate from liquid juices, which either heat or cold has condensed. But that which heat has dried, fire reduces to dust, and moisture dissolves. Not only does warm or cold water dissolve certain solidified juices, but also humid air; and a juice which the cold has condensed is liquefied by fire and warm water. A salty juice is condensed into salt; a bitter one into soda; an astringent and sharp one into alum or into vitriol. Skilled workmen in a similar way to nature, evaporate water which contains juices of this kind until it is condensed; from salty ones they make salt, from aluminous ones alum, from one which contains vitriol they make vitriol. These workmen imitate nature in condensing liquid juices with heat, but they cannot imitate nature by condensing them by cold. From an astringent juice not only

plain what it really is from which metals are produced. The best proof that there is water in their materials is the fact that they flow when melted, whereas they are again solidified by the cold of air or water. This, however, must be understood in the sense that there is more water in them and less 'earth'; for it is not simply water that is their substance, but water mixed with 'earth.' And such a proportion of 'earth' is in the mixture as may obscure the transparency of the water, but not remove the brilliance which is frequently in unpolished things. Again, the purer the mixture, the more precious the metal which is made from it, and the greater its resistance to fire. But what proportion of 'earth' is in each liquid from which a metal is made no mortal can ever ascertain, or still less explain, but the one God has known it, who has given certain sure and fixed laws to nature for mixing and blending things together. It is a juice (*succus*) then, from which metals are formed; and this juice is created by various operations. Of these operations, the first is a flow of water which softens the 'earth' or carries the 'earth' along with

A, THIN *vena dilatata*. B, THICK *vena dilatata*.

is alum made and vitriol, but also *sory*, *chalcitis*, and *misy*, which appears to be the 'flower' of vitriol, just as *melanteria* is of *sory*. When humor corrodes pyrites so that it is friable, an astringent juice of this kind is obtained."

ON THE ORIGIN OF STONES (*De Ortu*, p. 50) he states: "It is now necessary to review in a few words what I have said as to all of the material from which stones are made; there is first of all mud; next juice which is solidified by severe cold; then fragments of rock; afterward stone juice (*succus lapidescentis*), which also turns to stone when it comes out into the air; and lastly, everything which has pores capable of receiving a stony juice." As to an 'efficient force,' he states (p. 54): "But it is now necessary that I should explain my own view, omitting the first and antecedent causes. Thus the immediate causes are heat and cold; next in some way a stony juice. For we know that stones which water has dissolved, are solidified when dried by heat; and on the contrary, we know that stones which melt by fire, such as quartz, solidify by cold. For solidification and the conditions which are opposite thereto, namely, dissolving and liquefying, spring from causes which are the opposite to each other. Heat, driving the water (*humorem*) out of a substance, makes it hard; and cold, by withdrawing the air, solidifies the same stone firmly. But if a stony juice, either alone or mixed with water, finds its way into the pores either of plants or animals . . . it creates stones. . . . If stony juice is obtained in certain stony places and flows through the veins, for this reason certain springs, brooks, streams, and lakes, have the power of turning things to stone."

ON THE ORIGIN OF METAL, he says (*De Ortu*, p. 71): "Having now refuted the opinions of others, I must ex-

A, SOLID VEIN. B, SOLID STRINGER. C, CAVERNOUS VEIN. D, CAVERNOUS STRINGER. E, BARREN VEIN. F, BARREN STRINGER.

it, thus there is a mixture of 'earth' and water, then the power of heat works upon the mixture so as to produce that kind of a juice. We have spoken of the substance of metals; we must now speak of their efficient cause. . . . (p. 75): We do not deny the statement of Albertus Magnus that the mixture of 'earth' and water is baked by subterranean heat to a certain denseness, but it is our opinion that the juice so obtained is afterward solidified by cold so as to become a metal. . . . We grant, indeed, that heat is the efficient cause of a good mixture of elements, and also cooks this same mixture into a juice, but until this juice is solidified by cold it is not a metal." . . . (p. 76): "This view of Aristotle is the true one. For metals melt through the heat and somehow become softened; but those which have become softened through heat are again solidified by the influence of cold, and, on the contrary, those which become softened by moisture are solidified by heat."

ON THE ORIGIN OF COMPOUNDS, he states (*De Ortu*, p. 80): "There now remain for our consideration the compound minerals (*mistae*), that is to say, minerals which contain either solidified juice (*succus concretus*) and 'stone,' or else metal or metals and 'stone,' or else metal-colored 'earth,' of which two or more have so grown together by the action of cold that one body has been created. By this sign they are distinguished from mixed minerals (*composita*), for the latter have not one body. For example, pyrites, galena, and ruby silver are reckoned in the category of compound minerals, whereas we say that metallic 'earths' or stony 'earths' or 'earths' mingled with juices,

are mixed minerals; or similarly, stones in which metal or solidified juices adhere, or which contain 'earth.' But of both these classes I will treat more fully in my book *De Natura Fossilium*. I will now discuss their origin in a few words. A compound mineral is produced when either a juice from which some metal is obtained, or a *humor* and some other juice from which stone is obtained, are solidified by cold, or when two or more juices of different metals mixed with the juice from which stone is made, are condensed by the same cold, or when a metallic juice is mixed with 'earth' whose whole mass is stained with the color, and in this way they form one body. To the first class belongs *galena*, composed of lead juice and of that material which forms the substance of opaque stone. Similarly, transparent ruby silver is made out of silver juice and the juice which forms the substance of transparent stone; when it is smelted into pure silver, since from it is separated the transparent juice, it is no longer transparent. Then, too, there is pyrites, or *lapis fissilis*, from which sulphur is melted. To the second kind belongs that kind of pyrites which contains not only copper and stone, but sometimes copper, silver, and stone; sometimes copper, silver, gold, and stone; sometimes silver, lead, tin, copper and silver glance. That compound minerals consist of stone and metal is sufficiently proved by their hardness; that some are made of 'earth' and metal is proved from brass, which is composed of copper and calamine; and also proved from white brass, which is colored by artificial white arsenic. Sometimes the heat bakes some of them to such an extent that they appear to have flowed out of a blazing furnace, which we may see in the case of *cadmia* and pyrites. A metallic substance is produced out of 'earth' when a metallic juice impregnating the 'earth' solidifies with cold, the 'earth' not being changed. A stony substance is produced when viscous and non-viscous 'earth' are accumulated in one place and baked by heat; for then the viscous part turns into stone and the non-viscous is only dried up."

**THE ORIGIN OF JUICES.**—The portion of Agricola's theory surrounding this subject is by no means easy to follow in detail, especially as it is difficult to adjust one's point of view to the Peripatetic elements, fire, water, earth, and air, instead of those of the atomic theory which so dominates our every modern conception. That Agricola's 'juice' was in most cases a solution is indicated by the statement (*De Ortu*, p. 48): "Nor is juice anything but water, which on the other hand has absorbed 'earth' or has corroded or touched metal and somehow become heated." That he realized the difference between mechanical suspension and solution is evident from (*De Ortu*, p. 50): "A stony juice differs from water which has abraded something from rock, either because it has more of that which deposits, or because heat, by cooking water of that kind, has thickened it, or because there is something in it which has powerful astringent properties." Much of the author's notion of juices has already been given in the quotations regarding various minerals, but his most general statement on the subject is as follows (*De Ortu*, p. 9): "Juices, however, are distinguished from water by their density (*crassitudo*), and are generated in various ways—either when dry things are soaked with moisture and the mixture is heated, in which way by far the greatest part of juices arise, not only inside the earth, but outside it: or when water running over the earth is made rather dense, in which way, for the most part the juice becomes salty and bitter; or when the moisture stands upon metal, especially copper, and corrodes it, and in this way is produced the juice from which chrysocolla originates. Similarly, when the moisture corrodes friable cupriferous pyrites an acrid juice is made from which is produced vitriol and sometimes alum; or, finally, juices are pressed out by the very force of the heat from the earth. If the force is great the juice flows like pitch from burning pine . . . in this way we know a kind of bitumen is made in the earth. In the same way different kinds of moisture are generated in living bodies, so also the earth produces waters differing in quality, and in the same way juices."

**CONCLUSION.**—If we strip his theory of the necessary influence of the state of knowledge of his time, and of his own deep classical learning, we find two propositions original with Agricola, which still today are fundamentals:

(1) That ore channels were of origin subsequent to their containing rocks; (2) That ores were deposited from solutions circulating in these openings. A scientist's work must be judged by the advancement he gave to his science, and with this gauge one can say unhesitatingly that the theory which we have set out above represents a much greater step from what had gone before than that of almost any single observer since. Moreover, apart from any tangible proposition laid down, the deduction of these views from actual observation instead of from fruitless speculation was a contribution to the very foundation of natural science. Agricola was wrong in attributing the creation of ore channels to erosion alone, and it was not until Von Oppel (*Anleitung zur Mark scheide kunst*, Dresden, 1749, and other essays), two centuries after Agricola, that the positive proposition that ore channels were due to fissuring was brought forward. Von Oppel, however, in neglecting channels due to erosion (and in this term we include solution) was not altogether sound. Nor was it until late in the eighteenth century that the filling of ore channels by deposition from solutions was generally accepted. In the meantime, Agricola's successors in the study of ore deposits exhibited positive retrogression from the true fundamentals advocated by him. Gesner, Utman, Meier, Lohneys, Barba, Rössler, Beeher, Stahl, Henckel, and Zimmermann, all fail to grasp the double essentials. Other writers of this period often enough merely quote Agricola, some not even acknowledging the source, as, for instance, Pryce (*Mineralogia Cornubiensis*, London, 1778) and Williams ('Natural History of the Mineral Kingdom,' London, 1789). After Von Oppel, the two fundamental principles mentioned were generally accepted, but then arose the complicated and acrimonious discussion of the origin of solutions, and nothing in Agricola's view was so absurd as Werner's contention (*Neue Theorie von der Entstehung der Gänge*, Freiberg, 1791) of the universal chemical deluge which penetrated fissures open at the surface. While it is not the purpose of these notes to pursue the history of these subjects subsequent to Agricola's time, it is due to him and to the current beliefs as to the history of the theory of ore deposits, to call the attention of students to the perverse representation of Agricola's views by Werner (*op. cit.*) upon which most writers have apparently relied. Why this author should be (as, for instance, by Posepny, *Trans. Amer. Inst. Min. Engineers*, 1901) so generally considered the father of our modern theory, can only be explained by a general lack of knowledge of the work of previous writers on ore deposition. Not one of the propositions original with Werner still holds good, while his rejection of the origin of solutions within the earth itself halted the march of advance in thought on these subjects for half a century.

A FEW years ago a coal analysis was a complicated puzzle to most people. But recently it has become an economic necessity to scrutinize the coal bill as carefully as the food bill, and we have learned that a chemical analysis, when properly made from a sample properly taken, is the surest test of a coal's fuel value. This value is generally stated in terms of the British thermal unit (sometimes abbreviated to 'b.t.u.'), the quantity of heat necessary to raise the temperature of a pound of water 1°F. Manufacturers and large commercial houses have now found it a matter of economy to determine the heating value of fuel purchased for power or heating, and the coal-testing laboratory is considered quite as important as the accounting-room. The United States Government, in making its contracts for coal, requires a guaranty not only as to burning quality, but also as to ash content. It goes even much further than this and makes analyses of samples taken from each shipment to determine whether the standard set by the contract is being maintained.

Bag Filtration Plants

By ANTON EILERS

\*The first large bag-house used in connection with lead smelting was built about 1887 at the Globe Smelting & Refining Company's plant at Denver, Colo. When first installed it was not successful because the furnaces were run with hotter tops than is the custom at present. Following this first attempt I made a good many experiments to determine the temperature of the gas and the quantity of sulphuric acid which it contained. As a result of this work the length of the flues in all smelting works was greatly increased and there was no difficulty in treating the gases in bag-houses. It was found that in flues of a length of from 1000 to 1800 ft. there was no difficulty in accomplishing the end sought.

*Murray Plant Bag-House.*—This plant is at Murray, near Salt Lake City, Utah. The outside dimensions of the bag-house are 216 ft. 6 in. by 90 ft. 6 in.; height to roof trusses being 51 ft. 6 in. The total cost for construction was

compartment has a steel stack to conduct the gases to the atmosphere. When the stacks were built the joints were lapped in such a manner that condensed moisture finds its way to the outside of the stack, corroding the metal and giving the stacks an unsightly appearance. Considerable moisture also trickles down inside the stack and originally gave considerable trouble by rotting the bags. To overcome this a lead-lined pan is used under the stack and a lead gutter conducts the accumulated moisture out upon the roof.

The bags were originally shaken by hand, but in 1910 a new system was adopted and each row of bags was hung on a 1½-in. gas pipe suspended by a U-bolt from the old bag hooks. By means of a lever on the outside of the building this gas pipe can be given a horizontal motion of about 5 in., which effectually removes the dust from the bags. By this device forty-two bags are shaken at one time. Cotton bags were originally used and cost \$2.136 each at Murray. At the end of two years it was computed that the average life of cotton bags was seventeen months, eleven days. Had it not been for the adverse experience in roof construction and in the condensation of moisture in the

BAG-HOUSE, MAMMOTH COPPER SMELTER, KENNETT, CALIFORNIA.

\$127,194 including the cost of 4032 cotton bags, distributing flue, fans, motor, fan house, etc. The original roof construction had to be modified on account of the tendency of the gases to attack the nails. After two years' service the nails holding the 1-in. board sheeting were eaten to such an extent that a heavy wind carried away about one-third of the roof of one partition. It was evident that nails could not be depended upon for holding the roof down, and a new roof was put on top of the old one, allowing an air space between the two.

The bag-house is completely divided into four partitions running from floor to roof; and each compartment is further divided below the thimble floor into four chambers. A distributing flue 16 by 16 ft. runs the entire length of the bag-house, and connects with each of the sixteen cellars by means of 42-in. bulls-eye valves. On the top of the distributing flue is a smaller one which is used to conduct the gases from any of the chambers that are in process of sintering, and return them to the main flue. Each

stacks, the life of the cotton bags probably would have been longer. One compartment was equipped with woolen bags costing \$4.7185 each at Murray. These were put into use May 19, 1909, and no bags have been replaced to date. As a result of the superiority of woolen bags over cotton the use of the latter has been entirely discontinued. Filtering surface is provided at the rate of 3.45 sq. ft. per cubic foot of gas per minute. When one compartment is closed this rate is reduced to 2.59 sq. ft. per cubic foot of gas per minute, and as one compartment is usually closed most of the time, 2.5 sq. ft. was the basis used for calculating the number of bags needed.

All laborers connected with the bag-house are required to take a shower bath and change clothes before leaving the bath-house. Formerly rubber suits and helmets were furnished to the bag-shaker and foreman, but later it was found that these were not essential to the men, and that the main secret of good health was cleanliness, particularly avoiding eating their lunches with dirty hands and faces.

RECOVERY OF FUME, ETC., FOR ENTIRE OPERATION OF MURRAY PLANT BAG-HOUSE, JULY 7, 1907 TO FEBRUARY 29, 1912

	Charge smelted.	Fume recovered.	Fume recovered, per ton.	Charge smelted, %	Value of metals recovered.

Gain for 4 years and 8 months.....	\$6,547.09
The table shows the apparent gain from the installation of the bag-house in four years and eight months. But the figure does not include interest on the original investment, nor a fair percentage of same for amortization.	
If these two items were included, as they should be, we would have:	
Gain in 4 years and 8 months.....	\$6,547.09
6% interest on cost of \$127,194.89 for 4 years and 8 months .....	\$35,614.57
5% amortization for 5 yr. and 8 mo. ....	29,678.80
	65,293.37

Net loss in 4 years and 8 months..... \$58,746.28

On account of the advisability of extracting the high percentage of  $As_2O_3$  from the fume, the Murray fume has to be shipped to another works of the American Smelting & Refining Co., which is equipped with a plant for that purpose and works up the fume from a number of lead smelting plants. It is not good financial policy to provide every plant with an arsenic establishment, for it would be idle three-quarters of the time. But if the Murray plant had happened to be the one provided with its own arsenic establishment, the cost of working up the fume would not have been over \$5 per ton, thus diminishing the loss shown above by \$34,654, leaving the loss for four years and eight months still \$24,101.28.

These figures show that, taking the immediate financial outcome only, bag-houses are not profitable in lead smelting works, which treat ores low in the precious metals and especially in lead. But there is another consideration to be taken into account when smelting works are, like Murray, situated near farms and villages. This is the elimination of constant lawsuits, which are bound to be of frequent occurrence, when  $As_2O_3$  and the sulphates of lead and other metals are permitted to drop down into the fields. It must be decided therefore in the case of each smelting plant, whether it is not good business to expend the money for constructing and operating a bag-house, though an immediate profit is not apparent.

**Converter Bag-House System at Omaha.**—The Omaha plant of the American Smelting & Refining Co. converts a large quantity of leady copper matte. The gases from the converters are conducted through suspended flues. The flues lead to a fan 12 ft. diam. and 6 ft. wide, running at 140 r.p.m. and requiring 25 hp. The fan discharges into a bag-house containing 940 bags, divided into two compartments. With the acid-lined converters one set of bags will filter 1600 tons of lead sulphate fume representing 4500 tons of blister copper. The secret of long life of the bags seems to be in the use of long flues, permitting rapid radiation, and a good vacuum above the bags so that the gases are removed rapidly. The average vacuum at the fan is about 0.8 of an inch of water and at the converter from 0.07 to 0.15 inch.

The average temperature in the bag chamber is 140°F., varying from 100 to 180°F. Bags are made of Osnaburg sheeting, with a loop at the closed end, through which passes a 1-in. pipe or stick to support the bag. In the following table are some pertinent figures relating to the converter bag-house operations at Omaha.

**Blast-Furnace Bag-House System at Omaha.**—The blast-

furnace charge at Omaha is high in lead, rather above 40% than under. The recovered fume contains about 50% lead, considerable carbon, and arsenious acid. In sintering this fume, the arsenic is concentrated to about 20%. Some experiments were made to see how far the arsenic could be eliminated from the fume by roasting. Several results show a reduction from 13.1% As to 3.6% As.

The burned fume is fused in a small reverberatory, allowed to cool in pots, and then charged alone into the residue furnace of the lead refinery, reducing a little lead and removing silver. The antimonial and arsenical slag resulting from this operation is reduced in a blast-furnace, producing an impure lead which is later refined by a special process of fusion.

THE most ancient diamond-fields known are those of India, situated in the eastern portion of the Deccan mountains. From here were obtained the valuable historical gems. They have long ceased to be worked. The Brazilian diamond-fields were discovered in 1739, and have been famous for more than a century. The diamonds are for the most part enclosed in beds of itacolumite and alluvial gravels. The genesis of the precious stones has not yet been satisfactorily ascertained, but a conglomerate was discovered containing minerals similar to those in the kimberlite of South Africa. Ultimately an area of serpentinous rocks was detected, notably analogous to those of the Cape and of Arkansas. Important deposits of diamonds occur in the United States, which are presumed to owe their origin to glacial erosion of a district not yet located, but conjectured to be situated on the south side of Hudson Bay. In California and Indiana diamonds exist in the auriferous alluvium, and, although extracted from the beds of rivers, are associated with minerals similar to those in the kimberlite of South Africa. They are also sporadically found in New South Wales, Lapland, and the Urals. All these last-named deposits are of small import compared with those of South Africa, which supplies approximately 98% of the world's production.—*Revista Minera*.

WILFLEY TABLES numbering 17,000 are reported to be in use throughout the world.

# The Sudbury Nickel District, Ontario, Canada

By KIRBY THOMAS

The Sudbury nickel district is in western Ontario, about 260 miles northwest from Toronto, and 183 miles east of Sault Ste. Marie, the outlet of Lake Superior. It comprises an oval area, roughly 30 miles long by 16 miles wide, the longer axis being northeast and southwest.

## HISTORICAL

The extensive mineral deposits of the region first attracted attention about 1883, when the Canadian Pacific

PART OF ONTARIO.

railway was in course of construction across the area. Mining work was begun about 1886 at the Copper Cliff mine, by the Canadian Copper Co., which later became the nucleus of the International Nickel Co. The early mining was largely directed toward the recovery of the rich copper sulphide ore from the easily accessible outcrops on the south range, but the association of nickel with the copper in the ore was soon recognized. The creation of a wide market for this metal in the arts and industries, particularly as an alloy for steel, for armor plate, and special purposes, gave to the nickel content of the ore great importance. It was also found that the copper content of the ore deposits of the region was irregular and generally low, while most of the ore yielded nickel in commercial amounts. The known area of the copper-nickel bearing formation was greatly enlarged by exploration and it was found that the orebodies are generally large. For some years several companies in addition to the Canadian Copper Co. operated in

the district, but chiefly owing to metallurgical difficulties and to market conditions most of them discontinued work before 1903. The International Nickel Co. was organized in 1902, based on the merging of the more important mining properties, the smelter of the Canadian Copper Co., and the plant at Bayonne, New Jersey. About the same time the Mond Nickel Co. was organized in England. This company controls the Mond nickel-refining process. Several properties were purchased and a smelter constructed at the Victoria mine in the Sudbury district to produce matte for treatment in England by the Mond method. These two companies have for nearly ten years produced practically all of the nickel and copper of the district.

## NATURE OF THE ORE OCCURRENCES

The ore deposits of the Sudbury district are unusual, and consideration of their genesis and geological relations is of direct importance in exploration, development, and operation. All the strata of this region are early pre-Cambrian. The ore deposits are directly related to an enormous batholith, which in pre-Cambrian times was forced through the older complex eruptive and metamorphic rocks and spread out under a mass of sedimentary beds. Transportation of this vast amount of material from the interior of the earth resulted in a settling along the main fracture line of the eruption, and a subsequent tilting of the eruptive beds and of the overlying sedimentary beds so as to form a trough or basin, roughly platter-shaped, with the north and south edges dipping toward the centre and the ends somewhat flattened and more or less irregular.

The nickel-bearing eruptive is over a mile in thickness, and what now remains of it covers an area 30 by 16 miles. In the centre of this basin are the much altered remnants of the sedimentary beds. Erosion, both pre-glacial and glacial, has removed a great thickness of strata, practically all of the sedimentary beds, except in the centre of the platter, and has exposed the contact of the tilted nickel eruptive with the older rock so as to form an oval contact line. The ore is found mainly along and dipping with this contact. There are also some orebodies occurring in 'off-sets.' These are important as to size and grade. They are invariably accompanied by norite, indicating a primary genetic relation with the more numerous contact ore deposits. The 'off-sets' probably represent dikes or chimneys of the norite intrusive forced into cooling fissures or displacement fractures, presumably contemporaneously with the main intrusion. They are sometimes six or more miles long.

The lower portion of the nickel-bearing eruptive is classed as a norite, being a variety of gabbro with hypersthene. This grades toward the top, or the inner edge, of the basin into various acid rocks of the type of syenite and granite. In the norite, particularly near the contact, are found spots or 'blebs' of pyrrhotite with nickel and copper sulphides. These blend downward into the masses of pure pyrrhotite containing a uniform nickel and copper content and often platinum and palladium and traces of gold. The nickel occurs as pentlandite, a nickel-iron sulphide mineralogically similar to chalcopyrite. The copper occurs as chalcopyrite, and sometimes iron pyrite is found.

The generally accepted theory by Canadian and other geologists is that these orebodies represent the type of ore formation known as magmatic segregation, the theory being that the heavy copper, nickel, and iron minerals have settled out of the norite, their original source, by gravity. This theory is exceptionally interesting, and in the main it undoubtedly accords with the visible phenomena. However, I am inclined to believe that there has been considerable redeposition of the ores by water circulation, and that the magmatic segregation idea applies only to the primary source of the ore and not as a complete explanation of the ore occurrences as they exist today.

THE Lena company has mined and hoisted 470,062 cu. yd. of gravel from October 1, 1911, to July 22, 1912, and washed 330,004 cu. yd. yielding gold worth \$3,345,000. Men employed totaled 4060.

# Electric Hoisting at the Hecla Mine

By E. M. MURPHY

Eight years ago the Hecla mine, a lead-silver producer situated at Burke, Idaho, was producing ore from but two levels, the 300 and 600-ft. All hoisting was done with a 12 by 16-in. slide-valve, double-reel hoist. The hoist was operating to full capacity and was unsuitable for greater depths. As a new level was about to be opened, it became necessary to remodel the equipment or install a new hoist. The recent introduction of electric power from Spokane had made that available. By a series of tests conducted throughout the Coeur d'Alene district, it was found that it cost \$109 per year to generate 1 hp. with steam. Electric power was to be had for \$50 per horse-power-year. It was decided to substitute for the engines a motor-drive, of sufficient capacity to operate to the 900-ft. level, and ultimately install an entirely new hoist. After disconnecting the engines, installing a new shaft, and making a few minor changes, a 300-hp., 2300-volt, 514-r.p.m., variable-speed motor of the induction type was geared to the reel-shaft. The reels were supplied with  $\frac{3}{8}$  by 4-in. flat rope, and the duty of the hoist was about as follows: Cage, 1700 lb.; ore, 2600; car, 1400; rope, 2250; total, 7950 pounds.

The Bristol ammeter chart shows the combined current consumption of the hoist and mine motors. The large intermittent load is clearly shown; this produced harmful fluctuations in the voltage of the long lightly-loaded 60,000-volt transmission line from Spokane to the Coeur d'Alene. The power company received no compensation for the increased cost of producing power for this fluctuating load. In order to protect its system from similar excessive fluctuations of voltage in the future, the power company established a limit to the capacity of motors which it would permit to operate intermittently on its lines. When planning for its new hoist, it was therefore necessary for the Hecla company to adopt a device which would store energy during the periods when the demand for power is small, and return it during peak-loads. To meet this condition, it was decided to use an electric hoist of the Ilgner type, with the Ward-Leonard control.

The new hoist was installed during the spring of 1908, and began operation June 1 of that year. The equipment of the motor generator set is as follows: The set is self-contained, having a cast-iron sub-base, four bearings, and shaft; the driving element consists of a 450-hp., three-phase, 60-cycle, wound secondary motor, designed to operate between 2000 and 2300 volts. The generator is a 450-kw., 525-volt machine, with commutation poles to permit of its handling full-load current at any voltage between zero and maximum. Mounted on the shaft is a fly-wheel, 7 ft. 9 in. diam., weighing 29,000 lb. This fly-wheel consists of a cast steel spider, upon which is assembled a laminated steel rim. Upon the end of the shaft is mounted a 25-kw., 125-volt exciter, the armature of which is on the shaft of the set. The total fly-wheel effect of the set is 220,000 lb. at 1 ft. radius at 720 revolutions per minute.

The hoist motor is rated at 375 hp., 500 volts, 60 r.p.m., and weighs 51 tons. It is supplied with two bearings and is coupled to the reel-shaft through a forged flanged coupling. The reels are 5 ft. inner, and 12 ft. 8 in. outside diameter. Each reel is fitted with a Lane clutch and a post brake. At present each reel carries 1600 ft. of  $\frac{3}{8}$  by 4 $\frac{1}{2}$ -in. flat rope, this being sufficient to operate from the 1200-ft. level. The centre of the reels is placed 93 ft. 10 in. from the centre of the shaft. Lack of available space, preventing the placing of the hoist farther away, led to the adoption of flat rope. The sheave-wheels are 8 ft. diam., and the centres are 102 ft. from the collar of the shaft.

A paper presented at a meeting of the Spokane Section of the A. I. M. E., February 17, 1912. Excerpt from the *Bulletin*.

The dump is 55 ft. 6 in. from the collar, and the skip-pockets are 25 ft. below the station at the 600 and 900-ft. levels, and 30 ft. below at the 1200-ft. level. The skips are of 50 cu. ft. capacity, weigh 3500 lb., and carry 2.6 tons of ore per trip. Double-deck cages hang beneath the skips at all times; each cage weighs 2400 lb. The motor generator set, the slip-regulator, and switch-board, are situated in a room adjacent to the hoist-room. On the switch-board are placed the following instruments and equipment: one polyphase indicating wattmeter; one polyphase integrating wattmeter; one A.C. voltmeter; one A.C. ammeter; one double-reading D.C. voltmeter; one D.C. ammeter in the motor field; one D.C. voltmeter on the exciter circuit;

LARGE PEAKS PRODUCED BY 300-HP. INDUCTION MOTOR OPERATING OLD GEARED HOIST.

one graphic recording D.C. wattmeter; one Tirril regulator for exciter voltage; one DPST switch in the armature circuit of the exciter; one automatic, hand-operated, three-phase, 2300-volt, oil circuit-breaker; one generator-field switch; one exciter-field rheostat; one generator-field rheostat; one motor-field rheostat; one switch in the magnet circuit of the slip-regulator switches; two line-relays for the slip-regulator; one compensator for line-relays; current and potential transformers for the various instruments.

**Principle of Operation.**—In order that the fly-wheel shall give up part of its energy during the peaks, it is necessary to have some method of slowing down the set as the load comes on. This is accomplished by what is known as the slip-regulator. This device consists of a sectionalized resistance, of 13 sections, connected to the secondary of the induction motor. Each section can be short-circuited by means of an oil-switch operated by compressed air. The air-valves are controlled by A.C. magnets wound for 50 volts, the magnets being supplied with power from a 2300 to 50-volt transformer connected between the motor and its circuit-breaker. The magnet circuit comprises three circuits, accelerating, drop-out, and hold-in; each of the first two has a switch in series, which is opened and closed by its respective relay. The relays receive power from a compensator, which is excited from two current-transformers in the A.C. motor circuit. The relay switches can be set to operate at any desired value, within certain limits, by means of a dial-switch on the compensator, the one on the accelerating circuit being set to operate on a lower current than the one in the drop-out circuit.

With the A.C. circuit-breaker open, all the short-circuiting oil-switches are out, and the total resistance is in the secondary. To start the set, all that is necessary is to close the circuit-breaker; the starting current, being above that for which the relays are set, operates them, thus opening the accelerating and drop-out circuits. All the oil-switches, of course, remain open. As the set speeds up, the current diminishes and the relays close, causing an oil-switch to be pulled in. This short-circuits a section of resistance, the current increases, and the accelerating relay opens. As long as it remains open, the oil-switches remain out, with the exception, of course, of the one just closed, and this one remains closed, due to the action of the hold-in circuit. When the accelerating relay closes again, due to the fall in current, another oil-switch is closed. The opening and closing of the accelerating circuit, due to the increase and decrease of current, with its accompanying closing of oil-switches, goes on until all the oil-switches are closed, and all of the resistance is cut out of the secondary. In hoisting, the reverse of this takes place. As the load comes on, the relays open, and the last oil-switch to come in is the first to go out. This introduces resistance into the secondary, and the motor slows down, letting the fly-wheel take some of the load. Should the current rise again above the

discarded, which were intended to add to the safety of its operation and prevent abuse of the equipment by carelessness. A careless operator should not be tolerated on a hoist. The best safety appliance on any machine is a careful manipulator. In connection with the controller was an automatic retarder, designed to slow the hoist as the cage approached the top. Geared to the reels were two limit-switches, which controlled the opening and closing of a contactor. This contactor normally short-circuited a resistance in series with the generator field; within a certain predetermined distance of the dump, this contactor opened and the resistance was introduced into the generator field. The cutting in and out of this resistance was accomplished so suddenly that the commutation of the generator was affected. In addition, the failure of the apparatus to work at any time might have caused a serious accident, and it was deemed advisable to discard it.

A circuit-breaker was placed in the armature circuit of the exciter. Connected to this breaker, so as to open it, was an over-speed device on the motor generator set, it being assumed that during unbalanced lowering excessive speed might be obtained, due to the pump-back action. In practice, this high speed is not developed. An over-load trip and an under-load trip, in the motor-field circuit, could also

MOTOR GENERATOR SET.

HECLA ELECTRIC HOIST.

set value, another switch is dropped out; this operation can continue until nine switches drop out; four of the thirteen are not connected to the drop-out circuit, and are used in starting only.

The hoist motor is shunt-wound and is separately excited from the exciter. The current in the field can be adjusted by means of the rheostat in its circuit; when the proper adjustment is obtained, it is not necessary to change the setting. The motor is now operated with a field current of 90 amperes. The Tirril regulator is seldom used to keep the exciter voltage constant, as the drop in voltage during balanced hoisting is found not to be objectionable. In unbalanced hoisting its use is essential, but the wear on the contacts is severe.

The control of the hoist motor is effected through the field of the generator. The generator armature is connected directly to that of the motor; any change or reversal in the generator voltage is accompanied by a similar change or reversal in that of the motor. The control resistance is situated under the hoistman's platform, and has a large number of points divided into four sections, connected up after the manner of the well-known Wheatstone bridge. In the off position of the controller a perfect balance exists, and no current flows in the field of the generator; the movement of the controller disturbs the balance, and this diverts voltage from the resistance circuit to the generator field. The controller is operated with a lever and quadrant similar to those on the brakes and clutches; moving the lever away from the operator starts the reels turning away from him, while a movement of the lever toward him starts the reels in that direction. In the generator-field circuit, and situated back of the switch-board, is a rheostat for adjustment purposes; when once set, this needs no further attention. Mounted in front of the operator is a double-reading D.C. ammeter, which enables him to see the load on the hoist motor at all times.

As originally equipped, the hoist had several devices, since

open the breaker. There are times when the failure of the D.C. power might prove disastrous and be attended with fatalities. It is essential to prevent any accidental opening of the circuit by using nothing but manually-operated switches. The breaker was removed and a switch substituted. The over-speed device was connected so as to light a lamp, in front of the hoistman, in case the set speeded up. Should the occasion arise to cut the D.C. voltage off suddenly, it can be done by opening an exciter-field switch, placed in front and within easy reach of the hoistman.

The hoist is also equipped with an air-operated device for throwing out the clutches and applying the brakes in case of overwinding. Owing to the lack of sufficient head-room, this apparatus cannot be used. As a substitute, converging or 'tight' guides are used, together with spring hooks, which engage the cross-head and prevent the falling of the skip, should the cable break after the skip reaches the sheaves.

*Cost of Operation.*—Before entering into the cost of operation of the hoist, an explanation of the present contract, signed in 1908, will serve to show on what basis a settlement is made for power consumed by it. The contract runs for a period of five years and is based on a maximum demand as well as a kilowatt-hour consumption. It will be noted that it penalizes a better combined power and load factor than 61%. A power factor of 100% and a constant voltage of 2300 is here assumed in all the calculations of maximum demand. In a contract calling for a maximum demand of 100 kw., a minimum sum of \$335 (\$3.35 per kilowatt) is paid each month; this sum entitles the consumer to 43,550 kw-hr. (130 for each dollar). At the same time, the maximum of 100 kw. must not be exceeded at any time during the month. In case more than 100 kw. is the maximum, the minimum bill is increased by \$3.35 for each kilowatt in excess. For each dollar of this increase the consumer is entitled to use 130 kw-hr. If the kilowatt-hours used exceed 43,550, the excess is paid for at the rate

of \$0.0112 per kilowatt-hour. On the basis of 43,550 kw-hr. per month at \$335 each kilowatt-hour costs \$0.00769. This amounts to \$50 per horse-power per year. The peak on the hoist never lasts 5 minutes, so the power never costs more than \$50 per horse-power.

As the Hecla has but one hoist, the handling of all timbers, waste, etc., as well as the shifts, must be performed by it, in addition to the ore-hoisting. To give an idea of the work the hoist does, the following table was compiled for the period of time from August 1, 1911, to January 1, 1912:

ORE HOISTED			
	600-ft. level.	900-ft. level.	1200-ft. level.
Monthly average.			
Skips .....	448.2	1,993.6	1,993.2
Tons .....	1,168.0	5,164.8	5,202.6
CARS OF WASTE HANDLED			
	1200 to 600.	Top to 600.	Top to 300.
Cars, average .....	789.2	1,483.2	165.2
Timbers, Stulls. Wedges. lagging, and chute.			
Average.	64,335.4 ft. B.M.	15.8 cars	95,028 ft. B.M.

Average power consumed, 46,925 kw-hr., equaling \$361 per month. Total cost for power for each ton of output, \$0.0313.

In order to determine the cost per ton for power used during actual hoisting, a series of tests was taken, with the following results: From the 1200-ft. level 32 skips (83 tons) were hoisted in 33 minutes, with a kilowatt-hour consumption of 142. On the basis of \$0.00769 per kilowatt-hour, the cost of hoisting the 83 tons was \$1.092, or \$0.0131 per ton. From the 900-ft. level 14 skips (36.4 tons) were hoisted in 11 minutes, with a kilowatt-hour consumption of 50, and a cost of \$0.3854, or \$0.0105 per ton. From the 600-ft. level 14 skips (36.4 tons) were hoisted in 10 minutes, with a kilowatt-hour consumption of 40, and a cost of \$0.3076, or \$0.00485 per ton.

To run the set light for 1 hour requires 48 kw-hr., costing \$0.368. In service the set runs continuously during the 24 hr., with the exception of a period of about 4 hr. after midnight. After the power is cut off, the set will run for 1¼ hours, unless it is slowed down by hoisting, or the hand-brake on the fly-wheel is applied. The hoist was guaranteed to maintain one-quarter output of the mine working unbalanced from the 2400-ft. level (its ultimate depth). In order to test this feature, a load of 1773 lb. was added to compensate for the extra weight of cable to 2400 ft. This weight was obtained by placing a car with the required amount of ore in it on a cage-deck. The car was allowed to remain on the cage during the entire time of hoisting. Unbalanced hoisting was maintained at the rate of 11 trips an hour from 900 ft. for 3 hours. All temperatures at the end of this time were well within the guarantees. In May 1911 one of the clutch-arms broke, and the hoist operated unbalanced for a period of 20 hours, part of the hoisting being from the 1200-ft. level.

It would seem as though it would be desirable to keep the setting that would give the minimum input at all times. The objection to doing this is that the lower the setting, the greater the number of switches that drop out, and the slower the speed of the set becomes. When all nine switches drop out, it takes 55 seconds for them to come in again and for the set to accelerate to full speed. It takes from 6 to 8 seconds to load and dump a skip, and if the speed in hoisting is not to be sacrificed, the switch-setting should be such that the number that drop out can come in again in the time it takes to load and dump. In practice this is found to be about three. The setting, of course, has to be made for the lowest level hoisted from, or else the setting be changed for different levels. The upkeep of the equipment for the three years and eight months it has been in service has been extremely low. The hoist motor has needed no repairs, while the exciter has had but one new set of brushes. The generator requires about one new set of brushes per year.

The A.C. motor has been the only source of expense, and like trouble could occur to any motor. Three times it has suffered a grounded coil during a lightning storm. The winding is a three-bank concentric winding, and replacement of coils is a tedious affair. A new set of collector-rings was also put on this machine last December.

One noticeable feature of this installation is its noiseless operation and the ease of control. The motor can be reversed in an incredibly short space of time, and during loading and dumping the brakes are seldom applied. The wear of the brake-blocks is inappreciable, and the original set will no doubt last the life of the mine. The effect of the smoothness of operation is particularly noticeable on a cable, a service of from 10 to 14 months being obtained from each sewing, while the strands will last for years. The control is so accurate that no chairs are needed in the shaft to run on and off the waste-cars. Should the brake be removed when the skip is empty, the speed with which it will descend unbalanced is remarkably low. No matter how slow the speed is, the pump-back action is taking place, and during the trips that waste and timber are being lowered into the mine, power is actually restored to the line.

The hoist requires but one man per shift to operate it. Another advantage of the hoist is its ability to operate for a short time, even though the power be accidentally interrupted. The running-lights in the hoist-room are all lighted from the exciter, which enables the operator to see as long as hoisting can be continued. This installation has the disadvantage of consuming power, even though the hoist motor is not in actual operation. This is more apparent than it would be if the hoist were operating from greater depths, or handling greater tonnage. The effect greater depth has on the efficiency is shown from the tests. From the 600-ft. level, the cost per 1000 foot-tons is \$0.014, from 900 ft. it is \$0.0116, and from 1200 ft. it is \$0.0109. The effect greater tonnage would have on the cost per ton of output is shown by the following: Assuming that the mine double its output, the kilowatt-hour consumption per month would be increased by 17,231, at a cost of \$132.50. The total cost for power for each ton of output would be lowered from \$0.0313 to \$0.0213. Each hoisting problem has its own solution, and the Hecla company appears to have solved this one in a most satisfactory manner.

## New Method of Galvanizing Iron

The *Frankfurter Zeitung* reports as follows with respect to a new method of galvanizing iron: In order to protect iron objects from rust, it is customary to coat them with zinc either electrolytically or by plunging them in a bath of melted zinc after careful cleaning. The disadvantage of these methods is that a real fusion of the two metals is not obtained. As a result the zinc coating is likely to be attacked by the atmosphere. This may be avoided by a recently patented process which consists in so preparing the iron that the zinc gets into its pores. After steeping in sulphuric acid the iron is placed in a solution of mercury chloride and then heated, resulting in decomposition of the mercury chloride and precipitation of metallic mercury, which forms an amalgam with the iron on the surface. The iron is then plunged into a zinc bath heated to 500°C., where it remains three minutes. Iron galvanized by this process shows unusually strong adhesion of coating to metal. Microscopic investigation shows that the zinc penetrates into the pores of the iron, and in case a portion of the coating is worn or broken off, iron does not rust owing to the presence of sufficient zinc in the pores.

SALE of the Sayapullo Mining Co., of Peru, to Paris investors, has been sanctioned by the directors and also by a general meeting of the shareholders, thus validating the contract already made by Jose Balta. The shareholders' meeting also voted to issue the £10,000 in bonds which had been held in reserve.

# Cyanidation of Concentrate

By ROBERT LINTON

\*A series of tests recently made by me to determine the advantage or the reverse of cyaniding raw concentrate in place of shipping it to a customs smelter developed some interesting metallurgical features. The analysis of the concentrate was as follows:

Per cent.		Per cent.	
Insoluble .....	44.00	MgO .....	0.47
Fe .....	26.50	As .....	0.03
Cu .....	1.30	S .....	18.20
Zn .....	1.20	Ag .....	4.29
MnO <sub>2</sub> .....	0.41	Au .....	0.06
Al <sub>2</sub> O <sub>3</sub> .....	1.40		
CaO .....	1.75	Total .....	99.61

The silver occurred as sulphide, chiefly or perhaps wholly, in the form of argentite. The gold was in the silver sulphide. Agitation in water indicated that the concentrate was neutral, but when agitated with N/10 acid and titrated with N/10 NaOH it showed an alkalinity of 0.44%. The concentrate was ground to pass 200 mesh and the treatment carried on in a model Pachuca tank 10 in. diam. by 30 in. deep, with 1½-in. pipe for air lift and ¼-in. pipe for air feed. The first tests showed a constantly increasing alkalinity in the solutions used, although no lime was added to the charge after commencing agitation. An analysis of the solution after agitating five hours gave the following results:

Per cent.		Per cent.	
Total cyanide.....	0.0970	Ferrocyanides .....	0.0289
Free cyanide.....	0.0920	Sulphocyanides .....	0.0358
Protective alkali....	0.1433	Alkaline carbonates.	0.1407
Alkaline hydrates...	0.0762	Zinc .....	0.0040
Hydrocyanic acid...	0.0033	Copper .....	0.0688

There was no reaction for alkaline sulphides, although K<sub>2</sub>S probably formed and immediately combined with more potassium cyanide to form potassium thiocyanate, KCNS. This would seem to explain the increase in alkalinity observed, and to indicate that this increase in alkalinity involves a direct loss in cyanide. The reactions would be as follows:

## FIRST TEST

The increasing alkalinity of the first test is shown in the following records:

Hours agitation.	Sodium cyanide added per ton concentrate, lb.	Solution	
		KCN	P. A.
2 .....	..	0.045	0.10
2¼ .....	20	....	...
4 .....	..	0.16	0.11
6 .....	..	0.59	0.23
6¼ .....	10	....	...
8 .....	..	0.195	0.207
12 .....	..	0.115	0.22
12¼ .....	10	....	...
16 .....	..	0.165	0.235
16¼ .....	10	....	...
20 .....	..	0.235	0.268
20¼ .....	10	....	...
23 .....	..	0.285	0.28
23½ .....	15	....	...
26 .....	..	0.33	0.29
28 .....	..	0.23	0.34
30 .....	..	0.205	0.35
32 .....	..	0.165	0.358

No alkali was added during the test, the increase in alkalinity resulting from the decomposition of the solutions. Several bottle tests were made to determine whether or not lead acetate would react with the K<sub>2</sub>S and prevent the excessive consumption of cyanide. With less than 1% lead acetate, it appeared to have little if any effect; with 1% or over the increase in alkalinity above noted gradually disappeared, but at the same time the consumption of cyanide greatly increased. The results of five tests of agitating 10 gm. of concentrate with 50 c.c. solution titrating 0.73% KCN for 72 hours are as follows:

Test No.	Lead acetate added, %	KCN after 72 hr. agitation, %	P.A. after 72 hr. agitation, %
1 .....	None	0.22	0.056
2 .....	1	0.21	0.036
3 .....	2	0.205	0.025
4 .....	4	0.185	0.002
5 .....	8	0.047	0.000

The extraction of gold and silver in each case was practically the same.

## SECOND TEST

From a study of the preliminary tests an outline of treatment was formulated and a test run of 76 hours was made in the small Pachuca agitator. Details of this run are as follows:

Hours agitation...	Cyanide added per ton conc., lb. ....	Lime added per ton conc., lb. ....	Solution,		Extraction.	
			KCN, %	P.A., %	Au, %	Ag, %
2 .....	...	109	...	...	...	...
4 .....	62.6	...	...	...	...	...
7 .....	...	...	0.58	0.31	17.4	20.8
13 .....	...	...	0.18	0.35	54.9	40.5
19 .....	...	...	0.12	0.35	79.2	52.6
22 .....	62.6	62.6	...	...	...	...
25 .....	...	...	1.30	0.36	...	...
31 .....	...	...	0.91	0.44	79.2	63.2
37 .....	...	...	0.75	0.47	...	...
43 .....	...	...	0.59	0.48	...	...
45 .....	...	...	0.56	0.48	82.6	74.6
46 .....	62.6	93.9	(Fresh So'n)		...	...
48 .....	...	...	1.17	0.30	82.6	80.8
54 .....	...	...	1.08	0.35	87.3	82.2
57 .....	...	...	0.98	0.35	87.3	85.2
60 .....	...	...	0.92	0.39	88.5	87.8
62 .....	...	...	0.88	0.39	90.2	87.9
64 .....	...	...	0.87	0.39	...	...
66 .....	...	...	0.85	0.39	...	...
68 .....	...	...	0.82	0.40	90.2	89.1
70 .....	...	...	0.78	0.40	90.2	90.5
72 .....	...	...	0.78	0.40	91.1	90.6
74 .....	...	...	0.77	0.40	91.8	92.5
76 .....	...	...	0.77	0.40	92.1	92.7

## THIRD TEST

A third test was run, using less cyanide in solution, but higher protective alkalinity, and lead acetate equivalent to 3.5% of the weight of the concentrate treated, also raising the ratio of solution to concentrate to 3:1 (previous tests having been at 2.5:1). The results of this test were as given in the table on the following page, which also shows a progressive increase in protective alkalinites.

The results of all the tests run seemed to indicate that the most economical treatment was to grind the concentrate in a solution of about 0.2% KCN, then agitate in a 0.6% KCN solution, raising to about 0.8% toward the end of the treatment. Maintaining a high protective alkali proved to be of little benefit, about 0.10 to 0.15 being sufficient. The use of lead acetate appeared to be of no benefit in pre-

\*From the *Jour. Chem., Met. & Min. Soc. of S. A.*, July 1912.

venting consumption of cyanide, although the use of a small amount serves to keep the solutions clear.

Hours agitation...	Cyanide added per ton conc., lb....	Lime added per ton conc., lb....	Solution.		Extraction.	
			KCN, %	P.A., %	Au, %	Ag, %

## Copper Markets of the World

The following is taken from reports from the cities mentioned, published in *Daily Consular and Trade Reports*.

The use of copper for manufacturing purposes in the London consular district constitutes but a small portion of the total consumption of the United Kingdom. The greater part of the copper is required in the Midlands and the north of England, which contain such great industrial cities as Birmingham, Manchester, Newcastle, Sheffield, and Leeds. Liverpool, by reason of its situation, is the port which receives most of the copper imported into the United Kingdom from the United States. Some American copper is delivered at Swansea, but it forms a very small proportion of the total imports.

Liverpool is the principal port in the United Kingdom for the importation of copper ore and unwrought copper, taking about three-fourths of the former and nearly one-half of the latter. It may be accepted that all of the copper ore imported into Liverpool is smelted in this district, but diligent inquiry fails to obtain exact figures as to the local consumption of the unwrought copper. Neither manufacturers nor brokers will give definite information or even satisfactory estimates. The closest figures obtainable are that 70% of the imports of unwrought copper is used in manufacture in this district, 20% forwarded outside of the district, principally to Leeds and Birmingham, and about 10% re-exported to foreign countries. This re-export varies and was found to be one-third less in 1909 than in 1910, although the imports in 1909 were about double those of 1910.

Two of the manufacturers in the Liverpool district principally produce sheets, bars, and heavy plates for working into shape by copper-smiths, and known to the trade as 'copper bottoms.' Birmingham is the centre of manufacture of copper for kettles, pans, etc., and is the

largest purchaser. Copper plates are also purchased by Egypt and India for use in the manufacture of utensils, trays, etc. A third manufacturer produces copper telegraph and telephone wire. There are no copper smelters in Liverpool itself, but this district is probably the greatest centre for smelting in England; Swansea, which previously led, being now second. Near Liverpool there are 7 firms operating 9 smelting works, and 4 have offices in this city.

The sale of copper ore is principally through brokers on commission, and not on the market. In the case of the unwrought copper, which is warehoused in Liverpool, the manufacturers purchase it on the London Copper Exchange, and the product of the smelters is purchased either in this way or through agents, and through dealers who buy large quantities to dispose of later. This copper is sold on what is known as 'standard copper' terms, which include various grades, the basis being 97% pure copper. If upon delivery the percentage should be below 97% and not less than 96%, the purchaser is entitled to a deduction accordingly, but if below 96% and not less than 93%, a double deduction is allowed. If under 93%, the copper can be refused. On the other hand, if over 97%, excess must be paid.

Birmingham, by the variety of its industries, probably uses more copper for manufacturing purposes than any other city in the United Kingdom. There is a large and increasing consumption of copper, however, in London owing to the electrification of railways. Of the total imports of unwrought copper into the United Kingdom in the last three or four years, only about one-third was imported into London, but most of the re-exports were shipped from this district. The smelting and refining of copper and the making of articles of brass and copper have been important industries of Birmingham for many years. Not so very long ago nearly all of the copper or brass articles within the United Kingdom were of Birmingham origin, and this district properly claimed supremacy in the metal trades; but copper manufacture of various kinds has developed in other British cities, so that while Birmingham is still first, its leadership is by no means so unchallenged.

Several firms engaged in refining copper in Birmingham and vicinity are generally referred to as smelters, but as a matter of fact the copper that comes to them for refining has already been smelted and contains only traces of a few other metals. In the past, when it was customary for the copper ore to be brought to England, refining proper or smelting was really an important industry in Birmingham; but with the development of smelting and refining in the United States and in other copper-producing countries, and because of heavy freight charges for carrying crude ore from the seacoast to Birmingham, it became impossible for local smelters to compete with those more favorably situated on waterways, so what was left of the industry in England remained in the hands of refiners on the coast. Copper is used in the Birmingham district for the production of copper and brass sheets, tubes, and wire, for the manufacture of cartridge cases, bedsteads and bedstead mounts, fenders, brass foundry, lamps, pins, church bells, gas and electric fixtures and plumbing, motor accessories, and many other articles in which copper is required. The output of these products is immense, and the quality usually excellent, the copper, brass, and light metal trades generally giving employment to thousands of people.

Estimates as to Birmingham's proportion of the copper required for manufacturing in the United Kingdom vary materially. Unfortunately, there is no way of ascertaining the truth, because there are no statistics of the raw copper that comes into Birmingham, while the same copper will be used over and over again in various degrees of manufacture. The six largest Birmingham firms with copper and brass rolling mills are said to consume at least 30,000 long tons of copper annually, while other mills and industries are thought to consume as much more. The quantity of copper from America and other copper-producing

ing nations that comes to Birmingham or Great Britain fluctuates each year with trade requirements. Much depends upon the price at which the copper is offered and the supply available. At one time it may be more profitable for a copper manufacturer to buy Japanese or Chilean, Mexican, or other copper, while at another the American article may be more profitable to him because of the prices at which and the readiness with which it can be obtained at the moment. However, as American copper represents more than 50% of the production of the world, it necessarily stands pre-eminent in the market and must always command a considerable sale. Then the almost perfect purity, 99.9%, of the American cathodes, ingots, cakes, or wire bars that come to Great Britain gives American copper a high reputation with manufacturers, but what is regarded as the "independent attitude" assumed by the American companies that sell copper to England causes serious complaint on the part of those who are in the market for copper supplies. American copper companies are said to refuse to sell to England except on the American certified weight and not upon the weight of the copper on arrival. As copper cathodes must be lifted and handled about eight times on the way to the consumer in England, and as they are rough and easily abraded, it can be seen that the percentage of loss in weight is considerable. Copper merchants generally, at the normal price of copper, calculate this loss as an increased cost to them of about 60c. per long ton.

Another objection made to American copper is that cathodes are frequently of too great weight. Sometimes a cathode will be 86 lb., which is most strongly objectionable, although even this must be cut before it can be used in manufacture; but American cathodes are said not infrequently to weigh 125 to 160 lb. each, when they become a serious nuisance and occasion many complaints because of the great difficulty in handling them. It is stated that reduction in the size of cathodes from the United States would popularize American copper considerably, while if all American copper were shipped in cakes, ingots, or wire bars of reasonable weight, and not in extremely heavy cathodes, the objections raised on account of the loss during shipment and as to difficulty of handling would be met.

It was suggested by one manufacturer that if there were representatives of American copper companies with offices in Birmingham who went after the business with great energy, the sales of American copper might be further increased, particularly when the demand is slack and prices comparatively low. At such a time the services of a representative or merchant who is in touch with all manufacturers, who knows their requirements and the quality and character of the copper that they need, would be invaluable and materially broaden the sale of the American product. However, there are representatives of the great copper merchants in Birmingham who appear to be ready and willing to meet most of the requirements of the market.

It would seem as if there should be a good market in Birmingham for copper and brass sheets and electric and telegraph wires of American origin if regular supplies were available, provided, of course, pains were taken to study the market and ascertain the exact kinds, quantities, and sizes that manufacturers of brass and copper goods require, the usual terms of sale, and conditions of delivery; but the effort to sell such products by correspondence and without the most careful investigation would be futile. Some organization such as that by which semi-finished steel and iron from the United States and Germany are sold in England would be wholly desirable.

At Havre 65 to 75 tons of copper per day is used in manufactures, practically all by one consumer, La Société des Trefileries du Havre; the total local consumption is between 20,000 and 25,000 tons annually. Havre's imports of copper, however, are nearly three times this tonnage, having amounted in 1911 to 74,977 tons, consisting of 2569 tons of ore, 68,370 tons of pigs and sheets, and 4038 tons of scrap and filings. The United States supplied 5680 tons

of the pigs and sheets and 1510 tons of scrap and filings. Havre is the principal importing point for American stock and has practically a monopoly of the American copper trade with France. It must be understood, however, that this tonnage of copper received at Havre from America has heretofore not been traded in at Havre itself but at London. It is to handle the sales directly at Havre, and to save a present expense in London commissions, etc., amounting possibly to as much as 50c. per ton, that the Havre traders are endeavoring to create an independent exchange. Local bank conditions are quite adequate to such a market, and the hope is to buy direct from America hereafter, in so far as American importations into France are concerned. There is very little copper of any character exported from Havre. The total in 1911 was only 6634 tons to all countries, 5266 tons of which was copper wire manufactured in this city. The trade in scrap copper is insignificant.

The important element in the development of a direct American copper market at Havre will be the establishment of close relations between American and French shippers, without the intermediary of London or other traders. Steamship transportation is fairly adequate and cheap. British control of the Atlantic carrying trade and the necessity of making charters in London may possibly be used against the development of a direct market, but the consulate believes that American exporters will have no great difficulty on that score if they will make the proper connections at Havre. The transportation facilities of the port are excellent and are being enlarged to conform to the most modern practice. Freight connections with the United States are excellent. It is the expectation among French engineers that the French consumption of copper will continue to advance in fully the ratio shown for the past few years. Any artificially increased importations on account of the low prices prevailing in 1910 and 1911 will evidently be offset by greater consumption in manufacturing, the demand in France corresponding, as in other countries, to the expansion of industrial enterprises in the domestic field, and in the extensive enlargements of electric traction, transmission, and other systems which are heavy users. It is further to be pointed out that the Havre market is in direct touch with all parts of Europe and the United Kingdom, and that it is already headquarters for extensive direct dealings in coffee, cotton, rubber, woods, and other raw materials.

Russia, from January to May 1911, produced 454,526 poods (pood = 36.112 lb.) of copper, while the production for the same period of this year totaled 660,437 poods, an increase of 45.3%. This production for 4 months was distributed as follows: Urals, 350,664 poods; Caucasus, 198,906 poods; Siberia, 83,300 poods; smelters and refineries, 27,567 poods; total, 660,437 poods. It will be seen that the highest percentage falls to smelters and refineries, but the increased production of the Ural works is of much more substantial importance to Russia. Among the concerns of that region the largest gain in production is shown in the Kyshtin district, where the amount of copper produced rose from 56,675 poods in 1911 to 150,719 poods in 1912. The Akhtalsky works output advanced from 63,939 poods in 1911 to 89,230 poods in 1912. In the Bogoslov district 84,895 poods was produced during 1912, against 83,395 poods in 1911. The Spassky works increased its production from 48,767 poods in 1911 to 75,981 poods in 1912. The Caucasus Copper Co. (see *Mining and Scientific Press*, January 27, 1912) increased its output from 28,786 poods in the first four months of 1911 to 68,362 poods in the corresponding months of 1912.

EXPORT of coal from Formosa shows a considerable increase, while that of sulphur is declining. The principal market for both is in China. Favorable reports come from the gold mines in north Formosa. The production is somewhat larger, and by installing improved machinery the companies will be able to treat lower-grade ore in larger quantities.

## Mining in Korea

In Tung Chang 224 Korean 10-stamp mills are in operation, according to the *Seoul Press*. They still have 150,000 bags of ore to mill (20 bags to the ton). The ore averages 1 oz. of gold. The French company expects about Y60,000 royalty on this ore. The Korean methods are very wasteful, losing one-third of the gold. The French company is now putting up a 10-stamp mill on the property. The Allgemeine Electricitats Gesellschaft (A. E. G.) of Berlin, represented by Okura & Co. of Japan, has closed a deal to erect a 3000-kw. electric power plant to furnish power to the Oriental Consolidated Mining Co. in Yusan and the Chosen Mining Co. in Yeng Byen district. Contracts for power have been signed by these companies. The A. E. G. company expects to have the power plant in running order by March 1, 1913. Coal from Fushun will be used to generate power.

A new postoffice was opened June 14, 1912, by the Japanese Government at Kosung, Yeng Byen district.

NATIVE GOLD WORKING, KOREA.

Korea, for the special convenience of the Chosen Mining Co. Pyongan reports that the Mitsui Bussan Kaisha has decided to work the gold mines in Kaichon district, South Pyongan province, from August next, investing Y2,000,000 in the enterprise, and that the gold mine at Changsong, North Pyongan, will be worked by K. Yashikawa with a capital of Y1,800,000. The amount of gold exported through the Bank of Chosen during January 1912 was valued at Y516,080 (179,786 momme), and February 1912 176,367 momme, valued at Y493,217. A Korean named Whang, living at Kapsan, South Hamgyong province, found a nugget of gold as large as a man's fist, weighing 245 momme, and sold it to a Japanese, who sold it to the Bank of Chosen for Y1050 in March. The gold mines at Yusan (O. C. M. Co.) during February produced a total output of 738 lb., valued at Y252,800.

According to a report, the total amount of gold produced in the various districts in North Pyongan province during six months from January to June last was as follows:

District.	Value of gold produced. (Yen.)	Value of alluvial gold produced. (Yen.)
Kusong .....	33,600	.....
Sakuj .....	29,056	.....
Changsong .....	41,055	.....
Wiju .....	860	145
Uusan <sup>1</sup> .....	1,556,215	.....
Yeng Byen <sup>2</sup> .....	561,680	13,450
Taichon .....	6,260	.....
Totals .....	2,228,726	13,606

<sup>1</sup>O. C. M. Co. operating.

<sup>2</sup>Chosen M. Co. operating, but no reduction plant yet.

Of these amounts, about 70% was purchased by the local branch of the Bank of Chosen, 10% was exported to Antung prefecture by the Japanese, and 20% was purchased by the Japanese and Koreans of the province and other provinces.

## Queensland Mineral Land Law

The Queensland Government is introducing a bill dealing with prospecting and mining for coal and mineral oil, and this, it is proposed, should come into operation in May next. Among other things, this bill provides: That any person who desires to prospect Crown lands for coal or mineral oil may make application to the nearest warden for a license to occupy any Crown land described in the application, and not being of greater area than 2560 acres, for the purpose of searching thereon for coal or mineral oil, as the case may be, and shall pay to the warden a sum equal to one penny for every acre of the land applied for. The warden shall report on the application, and the Minister may grant a license for 12 months or refuse it. If an application for renewal is made before the expiration of the period of 30 days thereafter, the Minister may renew it for a further period of 12 months on payment of a sum of 1d. for every acre held. The license shall be canceled if the licensee fails to commence searching within 90 days of its issue, or such further time as the Minister allows, or if he does not make reasonable excuse, to take a lease of the land or part of it. Leases may be granted of land up to 640 acres for coal and 600 acres for oil, on payment of survey fee, and the first year's rent, which shall be at the rate of 6d. an acre. The period shall not exceed 21 years.

The surface area of the leases or licenses is restricted to 100 acres in the aggregate, and royalty must be paid in respect of leases as follows: For coal, during the first 10 years, 2d. for every ton of coal raised from the land, if it is situated more than 100 miles from a seaport or other place of delivery, and at the rate of 3d. for every ton of coal raised from the land if it is situated not more than 100 miles from a seaport or other place of delivery; and during the remainder of the term, in the first-mentioned case, at the rate of 4d., and in the second case at the rate of 6d., for every ton of coal raised; in every lease for mineral oil, at the rate of 5% of the gross value of all crude oil obtained during the term.

Conditions as to labor and expenditure are imposed, including: To work coal land by not less than one man to every 40 or part of 40 acres during the first two years, and by not less than one man to every 20 acres for the rest of the term; in the case of oil land, by not less than one man to every 15 acres during the period. As an alternative, the Governor-in-Council may, in the case of coal-mining, impose the following conditions: To spend during each half-year of the first two years of the term at least £100 for every 40 or part of 40 acres, and during the remainder of the term £100 in each half-year for every 20 or part of 20 acres of the land. In the case of oil mining, the sums to be expended under these alternate conditions are: To spend £100 at least in each half-year for each 15 or part of 15 acres, or such sum to be specified in the lease as the Minister may determine for each acre. The penalty for the first and second breaches of these covenants is a fine not exceeding £100, as the Minister may impose, and on non-payment of penalty or on a further breach, the lease may be forfeited. Work done under tribute will satisfy the labor covenant.

INVESTIGATIONS are being conducted by French and English engineers on behalf of the concessionaries who secured the exploitation of the Kolochugin mines, the Salirsky silver and gold mines, the chalk hills at the source of the River Tom, and the construction of a 150-mile railway from Yurga on the Siberian trunk line. It is assumed that the Yurga line will be the starting point for the projected railway which is to connect Siberia with Turkestan.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Water as an Indication of Ore

The Editor:

Sir—M. W. von Bernewitz' letter in your issue of September 21 reminds me that I had forgotten to write a few words on this subject. I agree with Mr. Rickard that the presence of water—in a lode—is a favorable indication. It marks a broken and shattered area, which would naturally be better suited for the reception of ore-bodies and their enrichment by subsequent migratory processes. Furthermore, a damp condition of the freshly broken face, in contrast to a dry or harsh appearance, is according to my experience one of the best signs of approach to valuable ore. But large flows of water are often due to post-mineral fissuring, and may be of no value as a sign of ore, except as indicating that the mine has not yet penetrated below the horizon to which surface waters may penetrate. A dry, dusty condition in the bottom of deep mines often seems to coincide with a lessened amount of quartz in the gangue, and a vein-filling consisting mainly of clay and crushed 'country.'

GEORGE E. COLLINS.

Denver, Colorado, September 26.

### What are Mining Profits?

The Editor:

Sir—I was rather surprised to notice that in a recent issue you criticized adversely the decision of a Colorado judge that the removal of ore from a mine is not depreciation. Carried out logically, the theory that ore removed is depreciation means that there will be no real profits in mining, and that no mining corporation need pay the corporation tax. This argument is rank sophistry. It is akin to a statement that because human activity does not add anything to or subtract anything from the material universe there is no profit in doing anything.

The profits of mining are just like any other profits—the difference between what money you put in and what money you take out. The steel maker buys his pig iron, converts it into steel, rolls it, and sells it. All these things cost money. If the selling of his steel gives him more money than he has spent, he has a profit. Similarly, a mining company buys a piece of ground, finds ore on it, puts up a plant to take out the ore, takes it out, sells it, and shuts up shop. Every dollar taken in over what is spent is profit.

But here we come to the point where the sophist gets in his work. The price paid for the ground is either made to appear vastly greater than it really is by attaching to it some fanciful capital stock valuation; or the real profits of the mine are paid to the owners of the ground as a cash purchase price. Practically all the mining land in the United States has been secured from the Government for a few dollars per acre. As soon as that land is sold at an advance for mining purposes a profit is reaped. The capital valuation of a mine can so easily be juggled in this way, and it is so often done, that the depreciation of it is certain to be a farce—a fanciful calculation for tax-dodging purposes. The word 'billion' is just as easily pronounced as 'million', and is just as easily attached to the articles of incorporation. The only depreciation the Government can afford to allow to mining companies is the full amount of their actual expenditure on actual plant and operation. Purchase of real estate should be considered as an investment purchased with profits. If profits are employed to make such purchases, that is no reason why they should not be taxed.

If the Government is going to allow depreciation of capital stock it will always be in a hopeless muddle. It should forget all about capital stock and make the companies pay on a plain statement of expenditures which should be interpreted by a plain and simple rule. Such a rule should exclude from the list of expenditures all sums spent for the acquisition or defense of mining rights. Let us suppose a mine takes ten years before it begins to pay. During that time the cost for prospecting, development, and plant is \$1,000,000. It then begins to earn \$200,000 a year. At the end of the first year of such earnings the mine has no profits, but instead a debit balance of \$800,000. It will not make any profits until at the end of its fifteenth year \$1,000,000 has been earned back. Its depreciation is then complete. From that moment it should pay its corporation tax on whatever surplus of income it may have over properly chargeable expenditures. If the plant is worn out or inefficient and it becomes necessary to renew it, all such renewals should be allowed as a direct cost. For instance, if during the sixteenth year of the company's operations it should decide to build a new mill and spend \$300,000 in so doing, while at the same time it earned \$200,000 with its old mill, the net result for the year would be a loss of \$100,000. The \$300,000 spent would be properly chargeable to 'depreciation.'

If during the seventeenth year the operation of the new mill should enable the concern to earn \$400,000, it could pay off the balance of \$100,000 due to depreciation, and for the first time in its history have a balance of real profits, namely, \$300,000. Thereafter, so long as the income exceeds the annual expenditures, and by exactly that amount, it should pay the corporation tax and it would be paying on real profits. The depreciation of the mine itself can never be undertaken intelligently. No one ever knows until it is worked out what it was really worth. The working out of it along the line briefly outlined above is what finally establishes its value. That value is in itself only the sum total of its profits. I have avoided all reference to the interest to be allowed on investments and the calculation of present values in order not to complicate the very simple line of reasoning.

J. R. FINLAY.

New York, September 26.

[We hope our readers will contribute their opinions on this important topic, which has not been adequately discussed by mining engineers. Our own will be reserved until later. —EDITOR.]

### Names, Right and Wrong

The Editor:

Sir—In your review of my 'The Hydrometallurgy of Copper,' in the issue of September 14, 1912, there are certain statements which I think require comment. In the spelling, or misspelling, of proper names the blame is thrown entirely on the author and on the proofreader, as for example: "It is too much, of course, to expect any metallurgist to spell the name of McDougall correctly, but a higher average of correct renderings of the other proper names throughout the book ought not to present unusual difficulty." But the difficulty is unusual, notwithstanding that the reviewer excuses the matter by the statement that "Typographical errors in a journal have some excuse." Since the book has gone to press I have found, in the various journals, different renderings of the same proper name, and unless one is aware of this in time, he has a right to assume that the name, as he finds it, is correct.

A very good illustration of this is found in the reviewer's own article. He uses two proper names, not referred to in the 'Hydrometallurgy of Copper': 'Mackay' and 'Braxeres', both of which are wrong, assuming that the patent record of one, and the official circular of the other, contain the correct rendering, which should be 'MacKay' and 'Baxeres', respectively. This shows an error of 100%

in the spelling of new proper names. Paraphrasing his 'jolt' to the metallurgists, it might be said that 'it is too much to expect a higher average from the editors of great mining journals.'

Now, it seems to me that instead of criticizing the professional metallurgist, who has neither the time nor the inclination to waste his life in the study of the vagaries and barbarisms of the English language, the blame should go where it properly belongs. If Bayonne is spelled with two n's instead of one, the culprit who originated the spelling is the one who should be executed.

I think, also, that a wrong impression is given in the matter of roasting. The statement is made, "Thus chapter III is largely composed of descriptions of experiments on the roasting of the gold telluride ores of the Cripple Creek district; an interesting subject, but one which has no visible bearing on the hydrometallurgy of copper." This is clearly a misstatement and a misconception. Out of the 62 pages of chapter III, only 2½ pages are devoted to tellurium, and only a little more than this out of 151 pages devoted to roasting in Part I. This mention was made to make the subject complete and on the basis that most copper ores contain some tellurium.

Anyone familiar with the Cripple Creek milling ore knows that it takes a very delicate test to show even a trace of tellurium, and the roasting operations are based entirely on the elimination of the sulphur from the iron sulphide. This being the case, there is no essential difference between roasting Cripple Creek ores for the extraction of gold and in roasting a similar cupriferous ore for the extraction of copper. These illustrations were used in preference to others, because it is not often that such data are available for tests passing through the stage of laboratory experiments and checked up in practice in a 100-ton furnace. The reviewer thinks that Part I, on roasting, might well have been omitted on the basis that the subject is fully treated in one of several texts that are generally available. Where? With the exception of short references in recent books on the general subject of metallurgy, most of which refer more particularly to roasting for smelting, there is little data in convenient form, on the subject of oxidizing roasting, especially in reference to copper leaching. Kustel's book, published in 1880, is still a valuable one on the subject, but much progress has been made since then. Hofmann's book on the 'Hydrometallurgy of Silver' contains the best exposition of chloridizing roasting in reference to silver ores, but this is largely confined to his personal experience.

I should like to have given much more space to the important subject of roasting as a preparatory treatment for copper ores, and copper ores containing gold and silver, but this would have gone beyond the limits of what was thought best. Most of the copper ores are sulphides, and my contention is that, as a rule, the best way to treat the sulphides by wet methods is to give the ore a preliminary roast. Any book which did not adequately take into account this important step would certainly be defective. In this respect, 'The Hydrometallurgy of Copper' has followed good precedents, such as Peters' books on copper smelting, Hofmann's book on lead smelting, Ingalls' book, the 'Metallurgy of Zinc,' and Hofmann's book on the 'Hydrometallurgy of Silver.' Surely, if these authors have found it necessary to devote a very considerable portion of their treatises to roasting, it would be necessary in a book on the hydrometallurgy of copper in the treatment of sulphide ores, for it is well recognized that there is a wide gulf between roasting for smelting and roasting for subsequent treatment by wet methods.

WM. E. GREENAWALT.

Denver, Colorado, September 19.

[Mr. Greenawalt evidently labors under a common confusion of thought in regard to the essential difference between works of reference and periodical publications. As he remarks, different renderings of the same name can be found in journals, but it does not follow that an author

may properly adopt in a work of reference the first form he may chance upon, without any attempt at corroboration. Journals are, except in the case of well known names, dependent upon their correspondents and contributors for accuracy in this regard, and most contributors and correspondents are somewhat careless. Not the least of an editor's tasks is the deciphering of proper names in the manuscripts submitted to him. Errors are not uncommon, and though deplorable, have the excuse that in the preparation of a weekly publication there is no time to carry out an extended search to secure accuracy. But in the preparation of a book, which is presumably to serve for permanent reference, the author owes it to his readers that all the material he presents shall be corroborated before committing it to print. Carelessness in this regard is evidence of hasty preparation and detracts greatly from the value of a book. Mr. Greenawalt cleverly scores a point with the names of MacKay and Baxeres, which form a case in point. Neither name is well known, and the first is given as Mackay in the list of members of the American Institute of Mining Engineers; the second does not there appear and the reviewer had never seen it in print. The effort which Mr. Greenawalt has made to discover the correct rendering (for which we are grateful) is very proper on the part of an author, but an utter impossibility for a reviewer, who is popularly supposed to rarely have time even to read the book under review. If reviewers and editors could be certain that the spelling given in the nearest reference work at hand was correct, their labors would be much facilitated. To condone inaccuracy in books of reference because errors can be found elsewhere is to set up ideals of imperfection. There is a present drift toward books written 'while you wait', which is the reverse of commendable. If an author has "neither the time nor the inclination" to make his book as accurate as possible he should refrain from writing it.

Mr. Greenawalt is conservative in his estimate of the amount of space he has devoted to Cripple Creek ores, since some reference is made either to tellurium or Cripple Creek on 19 of the first 34 pages of his book. It is not unnatural that he should believe that his presentation of the subject of roasting excels that of others, just as many college professors seem to find it necessary to write text-books for their classes. But most metallurgists will find that the elaborate presentation of the chemistry of roasting processes by Plattner, or the more condensed one by Peters in his 'Principles of Copper Smelting,' will amply meet their needs when supplemented by the works on the hydrometallurgy of silver and gold which are readily available. The authors our correspondent cites have discussed roasting at some length because the type of furnace required and methods of work are quite different for zinc, lead, and copper. Even in their case it is a question whether so detailed a treatment is altogether necessary. The output of modern technical literature is so great as to almost overwhelm the professional man, who is correspondingly grateful to authors who eliminate from their productions everything except that which is novel and necessary.—EDITOR.]

In tearing down an old iron blast-furnace, according to W. Heike in *Metallurgie*, a piece of galena weighing several kilograms was found beneath an old sow. The analysis showed lead, 80%; zinc, 3%; sulphur, 8%; there being an excess of metal over sulphur. Under the microscope metallic lead could be seen. Apparently the metallic part was a solid solution of tin in lead, while the sulphide was a solid solution of SnS and PbS. Experiments with artificially prepared material showed a eutectic at 80% ZnS and another at 40% SnS.

Water consumed by the twelve mines comprising the Kalgoorlie and Boulder Mines Water Trust, amounted to 29,932,600 gal. in June, a decrease of 3,305,400 gal. compared with the preceding month.

## Special Correspondence

### MEXICO CITY

#### REBEL ACTIVITY IN SONORA.—EXPORT TAX ON OIL.— PROGRESS IN HOSTOTIPAQUILLO.

Shifting of the scene of rebel activity from Chihuahua to Sonora has recently caused exciting times at three of the most important American mining districts in that state: namely, Nacozari, El Tigre, and Cananea. El Tigre was captured by rebels, but a little later they were driven out by federal forces, and when they left they took with them bullion valued at \$20,000. Federals and volunteer defenders prevented the taking of Nacozari, and plans for an attack on Cananea were not carried out. Americans in Cananea asked for arms and ammunition from the United States, and these were shipped from a Government arsenal. The Nacozari railroad, extending from Douglas to Nacozari, and the Southern Pacific line connecting Cananea and Naco, a border gateway, were cut, and serious interruptions of traffic resulted. However, operations have been continued, and the railroad lines now have been repaired. August was the best month reported

EL FAVOR MILL, HOSTOTIPAQUILLO.

by the Greene-Cananea so far this year, with the exception of April, May, and June, and the September figures are expected to show an increase over the August production of 4,044,000 lb. of copper. For the eight months ending with August, Greene-Cananea reports a production of 30,942,000 lb. of copper, 908,877 oz. of silver, and 4546 oz. of gold. The Moctezuma Copper Co., operating at Nacozari, had a production in the first eight months of this year of 23,056,321 lb. of copper, as against 17,140,003 lb. in the corresponding period of 1911.

Plans for putting into effect the new federal export tax on crude oil were stopped some time ago by an appeal to the Supreme Court of Mexico by the oil producers, headed by the Doheny and Pearson interests. The matter is still pending. The tax would amount to about 10 centavos per barrel, and is held to be excessive at this stage of oil development in Mexico. The Doheny interests estimate that the tax would cost them, at their present rate of export, \$900,000 per year. The Texas Oil Co. and the East Indian Refining Co., two concerns that are ex-

porting Mexican oil, are reported to have plans for the construction of pipe-lines from the Tampico territory to Texas points. The Doheny interests have entered into a contract with the Peñoles Mining Co., operating the mines and smelter at Mapimi, state of Durango, to furnish oil for fuel. It is expected that about 800,000 bbl. will be required annually.

The Cinco Minas Co., controlled by the Marcus Daly interests of New York, is getting ready for the erection of a 250-ton plant at the old Cinco Minas in the Hostotipaquillo district of Jalisco. Final bids have been received, and it is expected to let the contract within thirty days. Foundation work is in progress, and a surface tramway is being built to carry ore to the mill. A branch transmission line is being completed by the Chapala Hydro-Electric Co. Negotiations for a working bond on the San Pedro Analeco mines in the Hostotipaquillo district in favor of the United States Smelting, Refining & Mining Co., which were practically concluded, have been dropped, due to a disagreement as to terms. A 9-kilometre extension of the Southern Pacific line in Jalisco, from Magdalena to La Quemada, which will be of much benefit to many of the Hostotipaquillo district mines, has been completed. Shipments from the El Favor and Mololoa mines of the Makeever interests, in the Hostotipaquillo district, continue. From eight to ten carloads of El Favor ore, ranging in value from \$3000 to \$3500 per car, are sent to the smelter monthly. Only enough Mololoa ore to cover development expenses is being shipped at present.

### NEW YORK

#### THE COPPER SITUATION.—ANACONDA DIVIDENDS.—THE MEXICAN SITUATION.

The copper situation is as involved as it was a fortnight ago. Copper sales, both for export and for home consumption, are said to justify further advances in price, and 20-cent copper is apparently a certainty in the very near future. Sales are now being made for January, February, and March delivery. The engaging of copper for next year's delivery is considered a healthy sign, indicating that consumers are no longer fighting the advance in the market. A sale made by the United Metals Selling Co. for the account of the Copper Range, at 18.10c., attracted much attention. The sale was for immediate delivery and amounted to over 40,000 lb. The strike situation at the Utah Copper plant has had more effect on the metal market than on the shares of the company. None of the Guggenheim group have suffered by reason of the labor trouble, though despatches have indicated the possibility of the spread of trouble to Ely, Nevada.

As has been predicted for some weeks, the directors of the Anaconda Copper Co. ordered an increase in the dividend from 50c. per share to 75c. per share. Anaconda has paid a total of 134% in dividends: in 1900 and 1901, 13% per year; in 1902, 1903, 1904, 4%; in 1905, 11½%; in 1906, 19½%; in 1907, 26%; in 1908, 1909, 1910, 1911, 8%; and in 1912, so far, 7%. The chief interest in the Anaconda dividend is the possible action of the Amalgamated, which will receive from the current disbursement of Anaconda some \$2,338,000. It is undoubtedly the intention to make Amalgamated sell at par, and it is fairly safe to predict an increase in the dividend when the directors meet in October.

The 'atmosphere' of the New York Stock Exchange is hostile to mining ventures. Goldfield Consolidated lost a great part of its following when it 'went inside', and it is stated that steps are now being taken for withdrawing the shares from the Stock Exchange list. The Guggenheim enterprises are mostly listed on the Exchange, but it is probably a fact that they were more active when traded in on the Curb. Ray and Chino have evidently been in course of distribution, and are not yet as fully into the hands of the public as is desired. Both are to be important factors. Ray is conceded to be second in magnitude only to Utah Copper, while Chino will un-

doubtedly usurp the place of Nevada Consolidated as the cheapest large producer. Six-cent copper at the rate of three million pounds per month goes a good way toward justifying some of the things Lawson said about this property just before and just after the formation of the Chino Copper Company.

Conditions in Mexico are adding strength to the copper market in forcibly curtailing some production. The Phelps-Dodge company has been unable to make any September shipments from Nacozari, and the Douglas smelter output for September will show a consequent shrinkage of some 31,000,000 lb. Cananea is in better shape and shipments have been resumed. The Miami ores go to Cananea, and the smelter output is something like 7,000,000 lb. per month. W. H. Paul, manager of the Dolores, in Chihuahua, now controlled by the Mines Company of America, has just come from Mexico to attend the annual meeting of the company. He says that conditions are nearer to anarchy than at any time since the overthrow of Diaz, the chief trouble being that Madero's army is hardly lukewarm in its loyalty and makes no real effort to put an end to the revolution. Mr. Paul says further that intervention is the only solution, but that the policing of the country would be a staggering task, especially as all factions would unite and fight fanatically against the United States. One interesting angle to which Mr. Paul directs attention is the fact that Germans and Englishmen who from time to time are treated as was Mr. Paul, whose company was pillaged to the extent of \$50,000 or more, are simply waiting to present a bill for damages to the United States, on the ground that owing to the Monroe Doctrine neither England nor Germany is allowed to protect its citizens, and the United States must assume responsibility for damages incurred.

### BUTTE, MONTANA

PROGRESS AT BUTTE & SUPERIOR—BULLWHACKER LEACHING PLANT—GLENGARRY CHANGES HANDS.

The work of the Butte & Superior Copper Co. is the most important feature of Butte these days. Besides the importance of the zinc ore developed, the concentrating methods employed are new in several respects. The oil flotation section of the concentrator is working satisfactorily, but many changes and experiments are being carried out with the jigs and tables. At present the mill is averaging about 400 tons per day, practically all coming from the stock pile accumulated by the mine in past months.

The Chicago, Milwaukee & Puget Sound railway has begun the construction of its own tracks through Duran canyon. This will relieve the traffic pressure on the Butte, Anaconda & Pacific track, which is now being used by both roads, causing considerable inconvenience. Patrick Clark, of Spokane, president of the Bullwhacker Copper Co., says that a 50-ton leaching plant will be at once constructed on the property. If the leaching of copper silicate ores proves a success, the plant will be enlarged to 300 tons daily capacity.

The Tuolumne Copper Co. is sinking its shaft to the 2400-ft. level. This expense, together with lean ground found on the lowest levels, has decided the company to discontinue dividends for the remainder of the year at least. The Glengarry mine, in the southeastern part of Butte, has been purchased from the Glengarry Silver Mining Co. by F. M. Bell & Co., local mining brokers. The consideration is said to be \$100,000. The Glengarry was a famous silver producer in early days.

Churn-drilling of the dredging ground on Trout creek, in Missoula county, has been in progress during the past season. It is stated that the results were satisfactory. The Stoney Creek Coal Co. is preparing to ship coal from its property near Soudan. In the Bald Mountain mine, in Lewis and Clark county, belonging to Thomas Cruse of Helena, rich ore has been found at a depth of 800 ft. The 20-stamp mill and cyanide plant is run-

ning full capacity and turning out about \$10,000 per week.

Eastern investors have bonded the Blowout property at Rochester, in Madison county. Machinery will be provided to sink a shaft 500 ft. in search of copper ore. The Butte-Alex Scott Copper Mining Co., owner of the Alex Scott mine in Butte, has purchased the Moffat copper property in Bear gulch. This property is on a contact between granite and limestone, and has considerable development work. The new owners expect to begin operations immediately. The Boston & Corbin Copper & Silver Mining Co. expects to have its 200-ton concentrator, in Jefferson county, completed and in operation by next February. The copper occurs chiefly as chalcocite. The Montana Pulp & Paper Co. is to erect a paper mill at the mouth of the Yakt river in Lincoln county. The capacity of the plant will be 60 tons per day. This will create a market for magnesite and other non-metallic minerals used as fillers in paper manufacture.

### BOSTON

FAILURE OF DOW & CO.—AMSTER'S RETURN.—EXPANSION OF BUTTE & SUPERIOR.

The suspension of the firm of Stephen R. Dow & Co. from the Stock Exchange, and Mr. Dow's assignment to F. H. Williams, came as a surprise to Boston, though it was known that Dow was embarrassed, and had in fact been embarrassed for over a year. In August 1911 a crash came in the Dow stocks, but the firm was saved then from an assignment through various Stock Exchange houses subscribing to a fund which took care of its bank collateral, making an orderly liquidation possible. Mr. Dow's suspension and assignment affect a number of Lake companies and also the Corbin Copper Co., in the Corbin district, Montana. Richard M. Edwards, of Houghton, Michigan, who has been acting as president, was made Mr. Dow's successor as president of the Franklin, Indiana, North Lake, and Algomah copper companies. Since the first announcement the failure has taken on a more serious aspect. It is found that Dow & Co. owed North Lake \$157,000, Franklin \$80,000, Algomah \$28,000, and North Lake \$157,000, a total of \$297,000 indebtedness to these four Lake companies. Franklin has already asked for an assessment of \$2 per share and Indiana for \$1 per share. North Lake and Algomah will find it necessary to call assessments also, but have deferred the matter for the present. The directors of Franklin and Indiana, in their statement to the stockholders, say that the notes of \$80,000 and \$32,000, respectively, due these companies represent loans made by the treasurer, authorized by Stephen R. Dow, and without the knowledge of the board of directors. North Lake and Algomah are doing but little development work at present, but Indiana has a shaft 1100 ft. deep, with some 300 ft. more to go to reach the depth at which copper was found in the No. 2 drill-hole. Franklin is the only producing property in the Dow group, having, it is said, just reached the point where it is operating at profit. The Dow failure is a bad one, and will have a very depressing effect on many of the Lake shares for some time to come. The Corbin Copper Co. was not involved in the Dow troubles, as the company itself is a borrower. A little over a year ago, when the Dow difficulties first developed, the firm owed \$625,000 to the banks, having \$620,000 up in collateral. At that time a committee of bankers took over the liquidation of the loans, which has been accomplished, it is said, except about \$100,000, which is said to be fully secured. Dow had too many irons in the fire and was too risky a market plunger.

N. L. Amster, whose failure took place two years ago, is now recouping his fortunes very satisfactorily, it is said. His new purchase, the R. R. R. mine, near Patagonia, Arizona, has proved to be a winner, as the company is shipping regularly to the El Paso smelter. Mr. Amster has recently acquired other mining properties in the Southwest and appears determined to reinstate him-

self as a factor in the Boston copper market. He is an able technical manager, and assisted the Anaconda people in the early days in doing the deep development work which resulted in starting that company off on its remarkable career as a copper producer.

The stockholders of the Butte & Superior have authorized the proposed increase in capital stock from 250,000 to 350,000 shares, par value \$10. This increase is for the purpose of exploring properties under option and to provide funds in a measure for exercising options where it is found desirable to do so. Shareholders are offered 30,000 shares for subscription at \$37.50 in the ratio of one share for each eight shares held. Payments are to be made in two instalments, \$15 per share on October 15 and \$22.50 December 14. A. B. Wolvin, president of the Butte & Superior, has taken under option fifteen additional mining claims lying north of Butte & Superior ground. The transaction involves \$535,945, on which a preliminary payment of \$50,000 has been made. These claims include the Blaine, \$40,000; Robert Smith, \$60,000; William J. Bryan, \$35,000; Stonewall, \$60,000; Sunday, \$12,000; Lillie H., \$18,000; North Butte, \$18,000; Ella Curtis, \$18,000; Arctic, \$60,000; Sarah Alice, \$30,000; Washington, \$33,500; Peoria, \$20,000; Christie, \$50,000, and Copper King, \$29,465. These claims are in addition to about 20 which were previously taken under option for Butte & Superior interests. It should be pointed out that this ground a few years ago was considered worthless, being thought to lie outside of the ore-bearing boundaries of Butte. It is said that properties are being optioned and prospecting is being done  $2\frac{1}{2}$  miles north of the Speculator mine, or North Butte, which was once considered to be outside the mineralized zone.

### TORONTO, CANADA

#### ACTIVITY IN SILVER MINING.—COPPER FROM COBALT.— KERR LAKE STATEMENT.

Cobalt has been prominent lately owing to the marked revival of activity in the silver industry and the reopening of many old mines under the stimulus of the increased price of silver. The Nipissing has declared its regular quarterly 5% dividend and  $2\frac{1}{2}\%$  bonus, and presented a statement showing cash, bullion, and ore on hand to the value of \$1,368,876. The company has so far spent \$250,000 on the new low-grade mill out of this year's earnings, and the expectation is that it will be completed in November, after which the company will only ship bullion. There are 600 men and 50 drills at work. In the Meyer drift, at the 250-ft. level, an orebody several hundred feet long has been found which shows 4 in. of rich ore in addition to abundant milling ore. The 4th of July vein is yielding rich ore at a depth of 200 ft. La Rose stock keeps falling, owing to heavy selling supposed to be by insiders. The usual quarterly dividend of  $2\frac{1}{2}\%$  has been declared, but there is apprehension that it will not be maintained, as the 'silver sidewalk' of the Lawson property is gone and development at depth on that location has been disappointing. The company is developing the Fisher-Epplitt at a depth of 200 ft. and the Violet at 100 ft., and it is hoped that the results may be of a reassuring character. The 10-stamp mill that has been installed on the Casey-Cobalt will begin operations in a few days.

The Cobalt Lake appears likely to 'make good' before long. It produced 100,000 oz. of silver in July and a like amount in August, and the output for September will be about 120,000 oz. It is yielding ore from five good veins at the 220-ft. level. The Cobalt Central shipped this week a car of concentrate and high-grade ore, being the second since operations were resumed on the property. The Timiskaming has the deepest working in Cobalt, having started cross-cutting to tap No. 3 vein on the 650-ft. level. This vein yielded well at a depth of 575 ft. The formation at the lower level remains unchanged. The company recently sent 30 tons to the smelter at Denver and

was surprised to receive a payment of \$5 per ton for the copper contained in the ore, which is the first time that this constituent of the Cobalt ores has been paid for. The Silver Queen has been leased by the Cobalt Aladdin company, in which British capital is interested, and is being unwatered. The Cobalt townsite has undertaken the exploration of the portion of its property which underlies the tailing pond of the Northern Customs concentrator. The Waldman has been taken over on option by W. L. Malcolmson of London, on behalf of a British syndicate. The Beaver company is diamond-drilling on the Erie property underlying Kirk Lake, which it recently purchased.

The annual statement of Kerr Lake for the year ended August 31 shows a total income of \$1,044,418 and expenses of \$275,242. Dividends of \$762,000 were paid, leaving \$7179, which added to the previous surplus of \$709,817 leaves a balance of \$716,993. The gross production was 1,855,494 oz. of silver, as against \$2,388,420 for the previous year, and the cost of production was 18.30c. per ounce, as against 14.69c. the previous year. The estimated ore reserve was 6,690,091 oz. W. G. Nickerson, of Boston, has been elected president in place of Julius A. Lewisohn. The Trethewey has issued a statement for the first seven months of the year showing a production of 389,000 oz., valued at \$207,605; operating expenses and costs, \$106,311; leaving a profit of \$101,294.

### RHODESIA

#### GOLD OUTPUT FOR JULY.—NEW MINES PRODUCING.— PROMISING DISCOVERIES.

The July gold output of Southern Rhodesia was 57,122 oz. fine gold, valued at £240,514; an increase of 3248 oz., worth £13,647, over the preceding month. This is the third largest Rhodesian output and, coming at this time, is especially encouraging. Despite the prevailing drought, mining in Rhodesia is maintaining the rate of progress in production and development shown in the earlier months

WANDERER MINE, SELUKWE.

of the year. During June there were 168 producers, but the value of the gold output (£226,867) was slightly less than in May. In addition to the 53,875 oz. of gold produced, 16,014 oz. of silver was recovered, also 58 tons of lead, 16,539 tons of coal, and 6160 tons of chrome iron ore. On the whole, the mineral production for June was in excess of that announced by the Chamber of Mines for May.

The Shamva will be crushing at the rate of 40,000 tons per month in about 12 months time, and the Cam & Motor (which is now reported to have come under the Abe Bailey group control) will be milling on a fairly large scale by then. This latter property is stated to be in an excellent state of development, having about a million tons of 10-dwt. ore. Other mines which will enter the productive list soon are the Falcon and the Antelope. The former is a gold-copper property in the Blinkwater district and is being equipped on a 15,000 tons per month basis. The Antelope is situated to the southwest of Bulawayo, in a dry and arid part of Matabeleland. The property is therefore being equipped with a dry-crushing plant of about 4000 tons per month capacity.

A number of smaller concerns are in a fairly advanced state of development and may be expected to help swell the output within the next month or two. Several mines are increasing their reduction plants, the Bushtiek in the Essexvale district, for example. Important discoveries have been announced within the past week or two. Rich specimens have been brought into Salisbury from Lomagundi district, and it is claimed that a second 'Eldorado' has been found near the Ayrshire mine on the road to Sepolilo. In the Hartley area a large quartz deposit has been located. While little value can be attached to some of the reports which are being circulated, there seems no doubt that something of importance has been found, and further developments will be awaited with much interest. The native labor situation continues to cause anxiety. The number of natives employed in May showed a decrease of 4102 as compared with May 1911. The distribution during the month of April was: producing gold mines, 23,342; non-producing gold mines, 13,279; coal and other mines, 1124. The average number of natives employed on the mines for the first five months of the current year has been 35,786, or 3000 less than for the corresponding period of 1911. Colonel Heyman, however, presiding at the Chamber of Mines meeting recently, spoke most hopefully of the general outlook and anticipated an improvement in the unskilled labor position in the near future.

### JOHANNESBURG, TRANSVAAL

DIAMOND MINING PROSPEROUS.—OUTPUT FOR THE YEAR.—  
TRANSVAAL MINES.

Diamond mining in South Africa is prosperous just now, the demand for diamonds from all the old markets being brisk, while India has of late become a considerable buyer. In consequence prices are advancing, and in the fields more activity is being displayed, especially in prospecting operations. The total yield of diamonds in South Africa during 1911 was 4,891,998 carats, valued at £8,746,724, the average price per carat being 35s. The figures for the first six months of the present year have appeared, and form some interesting reading. They show the output to have been 2,392,255 carats and the estimated value £4,541,451. The production is somewhat less than anticipated, but the value shows an appreciation from an average of 35s. per carat from the whole of 1911 to nearly 38s. per carat for the first half of the present year. The Orange Free State possesses nine producing mines, several small mines having recently been started, but the total output of the Free State mines is only about equal in weight to one-half the output of the single diamond mine in the Transvaal. The value of the Free State diamond output is, however, practically equal to that of the Transvaal, the stones averaging nearly double the value per carat as compared with those of the Premier mine in the Transvaal. Of course, the principal centre of diamond mining in South Africa is Kimberley, where the De Beers mine produces about two-thirds of the value of the whole diamond output of South Africa, but probably less than one-half the number of carats. In the matter of output the Kimberley mines are being closely approached by the Premier mine in the Transvaal. There are only 17 producing diamond mines in the Union of South Africa, and their combined output will for the present year closely approach, if it does not exceed, a value of £10,000,000, of which more than one-half will come from Kimberley alone. Nine of these mines are in the Orange Free State, seven in the Cape province, and only one, the Premier mine, in the Transvaal. There have been strenuous efforts made of late to raise working capital for several worthless diamond-mining ventures at Rayton in the Transvaal, not far from the celebrated Premier mine. These are mainly resuscitated prospects, such as the Montrose and Schuller mines, which in the past, after lengthy trials, have proved worthless, and it is at least doubtful if they can now be made profitable.

### MELBOURNE, AUSTRALIA

NEW BROKEN HILL RAILWAY.—AUSTRALIAN LABOR IDEALS.  
—PROPOSED TASMANIAN AMALGAMATION.

The most important news of the month has been the announcement that the Public Works Committee has reported to the New South Wales Parliament in favor of the construction of a railway line from Condobolin to Broken Hill. This will be an extension of the main western line of the state, which runs from Sydney through Lithgow to Bathurst, and Blayney to Condobolin. This line will need to be extended some 373 miles to bring it to the great silver-lead-zinc centre, and the result should be of the utmost importance. Hitherto, although the field is situated in New South Wales, its output has had to make its way to a South Australian port, there being direct railway connection between Broken Hill and Adelaide, but none with Sydney save by the long roundabout route through Adelaide and Melbourne. Even when the proposed line is completed, it is not to be expected that Sydney will displace Adelaide as the port and the field, since the distance from the silver-lead city to the New South Wales capital will be about 700 miles as compared with a short run of only 334 miles to the South Australian metropolis. Why, then, should the line be regarded as of such great importance? The chief reason is that the Sydney-Condobolin line, with which Broken Hill is to be connected, passes through the western coalfield of New South Wales, a field of which Lithgow is the centre. Here is an abundance of coal of the highest quality, and there are also large deposits of ironstone and limestone. The annual consumption of coal on the 'Barrier' (as the Broken Hill field is still called in many quarters) is set down at 180,000 tons, and the New South Wales railway department expects that some of this will be taken from Lithgow once connection has been established. There is also the possibility of establishing a zinc industry at Lithgow, and if that comes about, there should be a heavy freight traffic from the Barrier to Lithgow, as well as from Lithgow to the Barrier. But there is also another aspect of the railway, which is of great consequence, not to Broken Hill merely, or even to the state of New South Wales alone, but to the whole of the progressive portion of the continent, since it will shorten by 24 hours the journey from Fremantle in the far west to Sydney.

The extraordinary attitude adopted by the Australian 'worker' toward work was illustrated last week in a speech made by the secretary of the Woodworkers Union at Melbourne. Solemnly and seriously this gentleman argued in favor of 'loafing', which he described as the ambition of every man who wishes to get on. W. Curtain justified the workmen in taking six weeks to do five weeks work, on the ground that by so doing they were saving men from unemployment. He did not, however, urge that for the five weeks work in six weeks, they should receive only five weeks pay. That is not a part of his creed.

An important amalgamation of Tasmanian mining interests is contemplated, the companies concerned being the Hercules, Primrose, and the Tasmanian Smelting Co. At present there is a keen struggle proceeding in the Hercules company, one group of shareholders being anxious to bring about the amalgamation, and a majority of the directors being opposed to it. There are two processes involved, those in favor of the amalgamation desiring the employment of the Oker process, through the medium of the Tasmanian Smelting Co., which is largely in the hands of the Bank, and those opposed to it desiring that the process adopted should be that which the Metals Extraction Co. of London has prated about for some years past but never done anything with. It seems likely that the amalgamation will gain the day, but even then they will have several stiff problems before them. Whether the Paga (Oker) process can be made to pay in Tasmania as it pays in Germany is a matter of grave doubt, and whether it will satisfactorily treat the ores of the district concerned on a large scale is also not proved.

## General Mining News

### ALASKA

#### CORDOVA

An automobile factory at Seattle designs and manufactures special cars for Alaska. The Burch auto-sleigh is equipped on the front with runners and at the rear with a pair of large disc screws in place of rear wheels and propelling device. The machine will be made suitable for towing freight in sleds.

#### FAIRBANKS

There will be 16 stamp-mills, with 60 stamps, in the Fairbanks district this fall. Cleary creek will have the most mills, as the district between Fairbanks creek and Cleary was the scene of the first quartz development and is much further advanced than others. There have been a number of hold-ups and robberies of sluice-boxes of late, and trouble is promised the offenders, if caught. There has been a fair at Tanana which had exhibits of all descriptions, the mineral section being under the supervision of J. M. Drury, who also lent his private collection.

#### JUNEAU

During August the 240 and 300-stamp mills at the Alaska Treadwell mine worked 28.15 and 30.68 days, crushing 31,080 and 51,716 tons, respectively. The yield from free gold was worth \$104,953, and from 1633 tons of concentrate \$94,386, making a total of \$199,399. Operating expenses amounted to \$79,596, and construction \$40,871, leaving the estimated net profit at \$76,879, the realizable value of the yield being \$197,346. Development covered 1047

Chicbagof Mine and Mill

Golden Gate Mine and Mill

KLAG BAY MINES AND MILLS, NEAR SITKA, ALASKA.

ft., and the stock of broken ore decreased by 30,271 tons.

The 120-stamp mill at the Alaska Mexican worked 30.70 days and crushed 20,643 tons of ore yielding free gold worth \$29,086, and \$33,309 from 413 tons of concentrate, the realizable value of the total being \$61,771. Operating expenses were \$28,045, and construction \$11,281, leaving an estimated profit of \$22,444. Development covered 299 ft., and the stock of broken ore increased 7990 tons.

#### VALDEZ

After a four-days trial, L. Gorman was found guilty of stealing \$29,000 worth of gold-dust from the Flat creek claim. The second trial of Bronson has begun. Mt. Wrangell, the best-known active volcano in Alaska, is again in eruption and throwing out volumes of smoke and lava. There are now at least seven vents, and with field-glasses lava may be seen coming from these openings and flowing across the glaciers. This is believed to be the cause of high water in the streams draining that district. From Kotsina it is reported that sulphur fume is so strong as to drive prospectors away from claims near Kotsina glacier.

### ARIZONA

#### COCHISE COUNTY

Negotiations are under way for the transfer of the World's Fair mine, in the Patagonia district, from F. Pow-

ers to the Copper Queen company; the purchase price is said to be about \$800,000. This district was one of the earliest opened in Arizona, the ores carrying silver. The World's Fair mine is 600 ft. deep. The R. R. R. mine, adjoining, is shipping 50 tons of copper ore per day to Douglas. There are a number of abandoned plants in the Patagonia and Harshaw districts. Owing to railroad communication being stopped, transport of concentrate to smelters has been delayed, and the Copper Queen company has shut down two reverberatory furnaces. This company is to erect a new hoist at the Sacramento, and a change-room at the Uncle Sam. A big mining suit is being heard at Tombstone. The infant heirs of P. Cunningham, through their guardian, E. Marks, are suing the estate of M. Costello for a half interest in 17 claims which sold for \$962,000 several weeks ago. Cunningham and Costello were old-timers in Arizona, and a partnership is alleged to have existed.

An examination of the metal contents of the porphyry formations of the district is now taking place at the Sacramento workings of the Copper Queen company. Results are being studied with interest. Orebodies at Bisbee have often been found between lime and porphyry, and it has been customary to look for them at such contacts.

#### GILA COUNTY

(Special Correspondence.)—About 75 men are employed at the Superior & Boston mine, and ore shipments, mostly from the Limestone vein, are being made to the Old Dominion smelter. At the Arizona Commercial mine the steel head-frame has been moved from the Eureka to the Copper Hill shaft. The shaft is being enlarged and retimbered. The Inspiration company has started a new inclined shaft which will connect with the main adit and will be used for lowering men and timber below the adit level. No. 1 shaft at the Live Oak mine is 575 ft. deep. No. 3 churn-drill hole at the South Live Oak has been stopped at 945-ft. depth, and is reported to have passed through 65 ft. of 2% copper ore. No. 7 and 8 drill-holes at the Southwestern Miami are 1206 and 910 ft. deep, respectively, in chalcocite-bearing schist.

Globe, September 26.

The Douglas Copper company, which owns 15 claims in the Ray district, is pushing work at its new shaft. At 40-ft. depth similar ore to that found in the Magma at 400 ft. was taken out. The Calumet & Arizona recently bought the property of the Consolidated Holdings & Trust Co., adjoining the Douglas claims. The American Smelting & Refining Co. now has control of the Lake Superior & Arizona group, and a smelter may be erected. A great area of country between Ray and Superior is either under option to or has been bought by large copper companies.

Railroad connection having been restored, it is stated that the Miami company has resumed shipments to the Greene-Cananea smelter. The mill has been making a recovery of 70.5% of late, and the September production should be about 3,000,000 lb. of copper. The Old Dominion is running four furnaces and employs 1200 men. The so-called east orebody has been cut on the No. 16 level and assays 16% copper.

#### GREENLEE COUNTY

The Detroit Copper Co. has a large number of men working on its power plant. The Arizona Copper Co.'s new steel and concrete warehouse, to replace the one destroyed by fire some time ago, is well under way.

#### MARICOPA COUNTY

The Swansea smelter people have been examining the Wickenburg district for sulphide ores for their plant, which is handling 450 tons per day, but its capacity is 750 tons. A reverberatory furnace is also being installed.

#### NAVAJO COUNTY

Mining men interested in the Arizona-Belmont mine have just inspected the property at Silver Bell. The main shaft is down 350 ft., and the ore carries 13% lead and

20 oz. of silver per ton. On the fourth level the vein is opening well in shipping ore. It is intended to increase the number of men, sink the shaft to 500 ft., and probably erect a 100-ton mill at an early date.

#### YAVAPAI COUNTY

Two hundred tons of the so-called onyx at the Mayer quarries is being shipped to the Swansea smelter for fluxing, and if suitable the smelter may require 2000 tons per month. This rock carries a high percentage of lime. The Pochontas company has developed good ore carrying gold and silver, a short distance from the old shoot which yielded high-grade silver ore. A hoist is to be erected, and the mill shifted near the mine. The Climax company will drive its new plant with electric power. The Harmony group of claims, in the Copper Basin district, is to be explored by drilling as well as by shafts.

#### YUMA COUNTY

Work has been started at the Arizona-Empire mine, and about 30 miners will be employed. High-grade ore, carrying 20% copper, is being sacked and hauled to Parker for shipment to smelters. Roads are being put in order for the use of auto trucks carrying ore from the mine to Parker.

### CALIFORNIA

#### KERN COUNTY

Work is being done at the 235-ft. level of the Merced mine, in the Stringer desert district. The vein is 12 in. wide, and 25 tons of high-grade ore is being hauled to the Sunshine mill. At the Red Dog mill, the Santa Ana property cleaned up \$5600 from 59 tons of ore.

#### PLACER COUNTY

The Bay company is building a dredge to work the gravel on the Freeman ranch, between Rocklin and Loomis. The Beaver Dredge Co. is taking out good gravel on the flat at the Captain Hawk ranch. The Barton gravel mine has been leased, and the Lost Camp property is to be sold.

The dredge at the Cash Rock, on the Middle Fork, is still handling profitable gravel, although part of it has previously been worked. All the lumber for the new dredge at Poverty Bar has been hauled, and building will soon commence. Moss and Young, after sinking 80 ft., have found rich gravel on the channel between Succor flat and Indian canyon. It runs as high as \$16 per car. The channel is drained through Watts adit. A new adit is to be driven 350 ft. at the Buckeye, and will open the mine 15 ft. below the channel. The Sierra Nevada Development Co. is employing a fair number of men on Ralston divide. It is developing the Pat Goggins mine, which is still profitable. Last year \$17,000 worth of gold was recovered. The Red Star mine is also being opened, and a 150-ft. adit and cross-cuts have been driven. The gravel is of a chocolate color, and is rich. The contact on the east is granite.

#### PLUMAS COUNTY

Extensive improvements are being made at the claim of the Gold Mountain Hydraulic & Dredging Co. on Willow creek near Bucks ranch. Mr. Fagg is in charge.

#### SHASTA COUNTY

The Riley-Bliss property, situated eight miles west of Kennett, has been leased for six months to C. Kunze. For the past 17 years the mine has been idle. At one time a 10-stamp mill crushed high-grade ore. Over 2000 ft. of development has been done. The main adit has a depth of 300 ft. from the surface, and has 4 ft. of ore in the face. The adit will be extended and ore sent to the Mammoth smelter, seven miles by road. The old stamp-mill is past repair.

#### SIERRA COUNTY

Due to the good showing at the Sierra del Oro mine, a good deal of attention is being given to what is termed the 'old Ironsides gold-bearing slate belt,' lying between the Sierra Buttes and the Alleghany-Downieville serpentine lodes.

This belt has a width of from three to eight miles, and extends north and south for about 20 miles. In Nevada county its richness has been amply proved. At the Sierra del Oro the results of driving the adit to get under old workings are being watched. The adit at the Bigelow quartz mine has been cleaned out, and the property examined.

At Forest, last week, 42 horses hauling mining machinery and other goods, passed through the town on one day, an unusual sight. A locomotive which used to haul gravel trains at the old Bald Mountain and Union Blue mines, at North Bloomfield, is being installed at the North Fork for the same purpose. The Wisconsin claim will be worked through the North Fork. G. F. Stone is superintendent.

Electric power will be used at the Quicksilver mine, near Alleghany. Arrangements have been made with the Middle Yuba Hydro-Electric Co. to construct a power line. Plant driven by motors has been ordered from New York and San Francisco. The mine will be unwatered and opened. At present the mill contains three stamps, but it will be enlarged. Ore 4 ft. wide has been cut by J. J. Guentherodt at the Thunderbolt claim, and San Francisco men have taken an option on it. The adit at the Steamboat gravel mine, above Poker Flat, is in 550 ft., in hard rock. A raise is being driven from the end of the adit. The Kenton mill had a short run, and is shut down for a few repairs. T. B. Garnier is in charge. An electric hoist is to be installed at the Bear Creek quartz mine, at American hill, and the shaft will be sunk deeper. Later on, the company may have to drive an adit in from the Middle Yuba slope of the hill, a length of 3000 ft., before reaching ore.

### COLORADO

#### CLEAR CREEK COUNTY

The orebodies at the Mendota are improving, and the mill is working steadily. The Mineral Chief mill is now treating ore from veins which have been opened during the summer, and is producing a good grade of zinc and lead. J. Hurley and B. O. Banner, lessees on the Harris lode, in East Argentine, have cut 14 to 18 in. of rich silver ore. The drill working from the top of Griffith mountain to connect with the Capital workings has been delayed for three weeks on account of the bit getting stuck at 600-ft. depth.

A number of lessees at the Gambetta property, on Republican mountain, are making shipments of high-grade zinc ore. Cunningham and O'Connell have a lode 4 ft. wide of good ore. A concentrating plant on the property, which is owned by the Joplin Mining Co., is proposed. Ore from the Boston mine, on Democrat mountain, is sent down by train to the mill-bins, then hauled to the Linn mill for concentration. The new assay office at the Capital mine is finished, and a branch from the Colorado & Southern railroad has been put in to the mill. Two cars of lead ore were shipped last week from the Santiago mine to the Salida smelter. The long drift at the Centennial mine shows 6 ft. of ore.

#### DENVER COUNTY

The Colorado zinc works was destroyed by fire on September 28, entailing a loss of about \$250,000, being uninsured. The building was a heavy frame structure of two stories, 60 by 200 ft., covered with corrugated iron, and had been there for 17 years. The plant was closed about 18 months ago, but used to concentrate zinc ores from the big mines at Leadville and Breckenridge, and employed from 25 to 50 men in treating 200 tons per day. The plant was owned by the Randolph Guggenheim estate, of New York.

#### LAKE COUNTY (LEADVILLE)

The Anderson adit, being driven from the Birdseye side into Prospect mountain, is in 635 ft., but no large orebody has been found, although several veins have been passed through. At the Mt. Champion, 40 men are working at the mine and mill, and the latter will be ready during the week. The mine is in good shape; on three levels the vein

is from 54 to 72 in. wide, worth \$12 per ton. The La Platte, lessees at the old Lime adit, Jonny, Forfeit, and Dome are all shipping regular lots of carbonate of zinc.

#### SAN MIGUEL COUNTY

During August the Tomboy mill treated 9500 tons of ore, which yielded \$33,500 in bullion and \$57,000 in the concentrate, a total of \$90,500. Operating expenses were \$46,500, and other \$10,345, leaving a profit of \$33,655.

#### TELLER COUNTY (CRIPPLE CREEK)

Work at the new electric pumps on the 1600-ft. level at the Golden Cycle shaft, has been delayed several times on account of flooding of the level. The frame of the foundations is in place, and it is hoped to fill in the concrete at once. Negotiations are said to be under way for leasing the Homestake mill, owned by the Rex company. The output of the district for the past eight months of the current year was \$9,640,000. Gas has been troublesome in the mines along the eastern side of Beacon hill, and the western end of Raven hill, of late, and is attributed to the indifferent weather. Ore has been opened a length of 65 ft., and 5 ft. wide, on No. 7 level of the main shaft, at a point 400 ft. west of the Nichols shaft, at the El Paso mine. As broken out, the basalt ore will average \$65 per ton. This orebody is a new one, and is south of the main or C. K. & N. vein.

### IDAHO

#### SHOSHONE COUNTY

At the election of officers of the Stewart Mining Co., held at Butte, E. Hickey was elected president, and E. H. Wilson, also of Butte, vice-president. W. Beaudry, of Kellogg, was appointed superintendent; M. W. Bacon, general manager; and R. A. Carnochan, treasurer. The Surprise and Highland Chief properties, now under one management, will use water power for all purposes. About 200-ft. head can be had, and water is said to be ample throughout the year. The Blaine & Emmett company has opened some promising veins which contain gold, silver, copper, and lead, by means of open-cuts and shallow adits. An adit is being driven to cut the ore at depth. The Sabina Mining & Milling Co. has been incorporated, and will prospect four claims situated at the Summit. E. J. Duff is president and manager. On October 4 the Bunker Hill & Sullivan company will pay dividend No. 181, amounting to \$65,400, making the total to date \$13,780,950.

### MONTANA

#### SILVERBOW COUNTY

(Special Correspondence.)—Before long it is expected that the companies operating in the district will discontinue Sunday work, as enough ore can be mined and hoisted in six days to keep the smelters at Anaconda and Great Falls going for seven. Owing to hard ground, slow progress is being made in cutting through from the Gagnon to the Davis-Daly. So far about 700 ft. has been finished out of a total of 1600 ft., and it will take about 150 days to get through. This connection is for the purpose of getting under the rich orebody which is thought to be in the Silver King at depth. The Barnes-King has 25 men at work; the shaft was found in good order, and work is being pushed to make connection with the orebody in the North Moccasin. The Kendall Electric Co. will supply all the power needed. J. D. Ryan has been inspecting the Amalgamated company's properties, and appeared to be quite satisfied with the general appearance of the mines. The extension of the Butte, Anaconda & Pacific railroad will be finished to Georgetown by November 1. At the Southern Cross mine 35 men are busy enlarging the shaft to 300 ft., when it will be sunk a further 200 ft. Unless a settlement is soon brought about, it is likely that a big lawsuit will take place, involving property in the northern district and in the vicinity of Butte & Superior. The case is somewhat complex. T. F. Cole and associates have several properties under option, east of the Butte & Superior, and adjoining the Butte & Lon-

don, and are said to be preparing to float another large Butte company, in connection with which they have taken control of the Butte & London Development Company.

Butte, October 1.

### NEVADA

#### CHURCHILL COUNTY

During August the Nevada Hills company treated 3386 tons of ore yielding bullion worth \$86,678, with an extraction of 93.3%. The month's profit was \$53,338. Recovery from concentration was 26.9%, and from cyanide treatment 66.4%, while the total cost was \$9.85 per ton.

#### ESMERALDA COUNTY

The Southwestern Mines Co. has completed the deal whereby it now owns the Great Western company's property at Hornsilver. In a cross-cut from the west drift on the 800-ft. level at the Jumbo Extension, not far from the boundary line of the Clermont claim of the Consolidated, a new orebody of good grade has been opened. The drift between the 800 and 900-ft. levels, east toward the Velvet claim of the Merger is all in ore, 24 in. of which is worth over \$100 per ton. The Florence-Goldfield company is shipping high-grade ore again, which is coming from an intermediate drift between the 250 and 350-ft. levels, 800 ft. north of the shaft. The Yellow Tiger company is to be reorganized, and the capital may be increased from \$2,000,000 to \$4,500,000.

#### HUMBOLDT COUNTY

Twenty-four lessees are working at the Seven Troughs property, mining about seven tons of fairly low-grade ore daily. On the 52-ft. level, the south drift is in 215 ft., with 18 to 24 in. of ore averaging under \$20 per ton; a south drift on the 110-ft. level is being started on the silver vein; from the 300-ft. level north the best ore is being mined; on and above the 230-ft. level, there is 12 in. of quartz worth about \$20 per ton; the 300-ft. level has been stoped within 20 ft. of the 230-ft. level; and a good deal of ore is being stoped from between the 600 and 700-ft. levels.

#### LYON COUNTY

Within the next 30 to 60 days, the Nevada-Douglas company hopes to increase its ore shipments to 500 to 700 tons per day, instead of the present 300 to 400 tons. The 900-ton furnace of the Mason Valley company, at Thompson, has been blown in; and the other furnace will be overhauled and enlarged, making the plant capacity of 2000 tons per day. J. Sommers, former owner of the Ludwig mine, has taken an option on the Blue Jay claims for \$50,000. About 16 years ago diamond-drilling showed 40 ft. of 6% copper ore below the 400-ft. shaft. At this time there was a long wagon haul to railroad, and no smelter nearer than San Francisco, but there have been changes since then in the district. A complete plant will be built as soon as possible. At the New Yerington the engine and compressor house is about finished, and men are now stoping ore in the adit. Twelve miners are driving No. 2 adit of the Yerington Mountain Copper Co. It is in 300 ft., and about 70 ft. remains before cutting ore.

#### NYE COUNTY

The mines at Tonopah produced 10,874 tons of ore, valued at \$271,850, during the week ended September 28. At the North Star the drift on the new orebody at 1250 ft. was extended 14 ft., where it is 4 ft. wide, assaying about \$810 per ton. The ratio of gold to silver is about 1 to 1, against the usual ratio of 1 to 100 for Tonopah ores. A shipment of this ore is now mined. On the 600-ft. level of the Jim Butler, the Fraction vein is over 40 ft. wide in the cross-cut. It shows a series of small veins of ore from 1 to 36 in. wide, carrying fair average bullion content. The Tonopah-Belmont has opened a new orebody on its No. 12 level. Last week 66,239 oz. of bullion, worth \$51,000, was shipped. The West End mill is now treating 150 tons per day, by crushing through a coarser screen at the batteries, and giving the tube-mills more work. The Tonopah Mining Co. has declared a dividend amounting to \$400,000, payable

October 21. The MacNamara mill is treating 67 tons per day.

#### STOREY COUNTY

About 40 tons of old tailing is being handled daily by the experimental machines at the Morgan dredging and concentrating plant on the Carson river. It is said that results are satisfactory, and 100 tons per day will be treated later on. During the week ended September 28 the centrifugal pumps at the 2500 and 2310-ft. levels of the C. & C. shaft, at the Comstock, worked 168 hours, and the pump at the 2500-ft. winze station of the Ophir also worked full time. Twenty-one shifts were worked at the Mexican and Ophir south air-drift. At Ward shaft the water is 50 ft. below the 2150-ft. station. The Mexican mill treated 438 tons of ore valued at \$38.40 per ton, with 95% extraction. Joint work was done with the Union and Sierra Nevada, and shipments included five bars of bullion to the California smelter. The southwest drift on the 2500-ft. level of the Ophir shows an improvement in formation over the previous week. The new cyanide plant is being pushed ahead. The new air-compressor at the Union shaft is at work. The Crown Point mined 521 mine-cars of ore assaying from \$7.96 to \$9.85 per ton. Milling will be started at the Yellow Jacket mill this week.

#### WHITE PINE COUNTY

The following letter has been issued by the general manager of the Nevada Consolidated and sent to the various departmental officials: "Based on copper selling price of 16c. per pound, and effective October 1, 1912, the wage-scale of all employees of the Steptoe Valley Smelting & Mining Co. will be increased over the present schedule as follows: All employees now receiving \$3 and over, will receive an increase of 25c. per day; all receiving less than \$3, will receive an increase of 20c. per day; this increased wage to be subject to adjustment when the market selling price of copper metal falls below 16c. per pound." The Federation of Labor does not consider the above offer enough and wants an increase of 50c. per day and recognition of the union by the company.

At 8 o'clock on October 2 the Nevada Consolidated mines were shut down following the strike order issued the night before. About 3500 miners in the district are affected. The county commissioners have closed all the saloons. The wage demanded by the union is \$3.50 per day for shovelers and carmen; \$4 for miners and timbermen; \$4.50 for shaftmen; \$5 for work in wet shafts; \$3.50 minimum for skilled mill and smeltermen; and \$2.25 to \$2.50 for common labor. The recognition of the union is demanded as at Bingham.

### OREGON

#### BAKER COUNTY

A considerable number of men are now employed at the Bonanza mine, and much development is planned. For some time they have been driving on one of the numerous small veins which seem to connect with the orebody which made this mine of note years ago. A good while ago an adit was driven 1800 ft. into the mountain, and it is intended to clean this out and extend it. The mine is owned by F. Moore, of Pittsburg.

### UTAH

#### JUAB COUNTY

It is reported that the Telluride and Knight power companies will consolidate before long, thus controlling nearly all the power business in the State. Both are doing business in the Tintic district, and some of the larger mines may change their steam-plants to electric. The new ore-house at the Eagle & Blue Bell is almost finished. Twelve carloads of ore were sent out last week, and good ore is opened at the 700, 1000, and 1300-ft. levels. The Swansea maintains a daily output of 100 tons of ore, which contains 8 oz. of silver, 50c. in gold, and \$4 in iron, which up to 20% brings 10c. per unit, and above this, 15c. per unit. In August the Chief Consolidated shipped over 4000 tons of ore. Another boiler of 150 hp. has been built in, making the boiler capacity at 450 horse-power.

The annual report of the Swansea Consolidated company gives the following details:

Development done, feet.....	2,428
Ore production, by lessees, tons.....	181
Ore production by company, tons.....	10,700
Metal content:	
Gold, ounces .....	452
Silver, ounces .....	129,276
Lead, pounds .....	97,885
Receipts .....	\$92,625
Expenses .....	\$83,497
Cash balance .....	\$8,128

The new 4-drill electrically-driven air-compressor, recently erected, and the electric station pump, have reduced working expenses. The main shaft is down 940 ft., and a pump station will be cut out. All work has been concentrated on the 800, 850, and 940-ft. levels.

#### SALT LAKE COUNTY

The United States S. R. & M. Co. has paid its regular quarterly dividend of 87½c. per share on the preferred stock. The common stock received 75c. per share, an increase of 25 cents. The lead furnaces at the Midvale plant are running practically full time of late. The Centennial-Eureka has been one of the best holdings of this company. The new coal property acquired is proving of great value. There is plenty of coal, and it is clean and of good quality. Present shipments are about 750,000 tons per year.

Thirty-four tons of concentrate has been sold by the Columbus Consolidated company for a net return of \$1537. The average contents were 0.015 oz. gold, 44.5 oz. silver, 9.5% lead, 9.05% copper, 7.8% zinc, and 17% iron.

During the past week there has been little of importance happening at Bingham, the district is quiet, and a waiting game is being played by the mine operators and the strikers. The sheriff has about 400 armed police in his charge; he has toured the hills about the mines; and gave orders to arrest any strikers who fired, and to clear the hills or breastworks at the first sign of hostile action. There have been reports that the mine owners are making preparations to resume work, and strike-breakers arrived to start, but no work is being done yet. The state governor tried to make arrangements for a conference between both parties; but the Western Federation of Miners will not meet the operators, without reference to the unions. L. G. Skliris, the Utah Copper company's employment agent, who was accused of accepting bribes for employment, has resigned, and denies such allegations, although the men say they can prove them. C. Darrow offered to arbitrate at Bingham, but nothing has come from his offer. Three boxes of dynamite were found under the Freeman canyon bridge, but union men deny knowledge of its being there. The district produces 12% of the copper output of the United States. At the Tooele smelter, three McDougall furnaces have been shut down, being short of concentrate for roasting. F. A. Heinze and S. Guggenheim passed through the district during the week.

#### SUMMIT COUNTY

The new mill of the Mines Operating Co., at Park City, is ready for work to treat the complex ores of the Ontario mine, of which there are said to be 700,000 tons worth \$8.67 per ton. The plant is of 50-ton capacity and uses lixiviation.

There are about 1400 men employed at the Park City mines, which are producing 6000 tons of ore per month. During the week ended September 21 four mines sent out 1288 tons of ore. Encouraging developments have been proved on the 200-ft. level of the New York mine. A shipment of ore is ready for the market. Work at the Snake Creek adit is going on as usual, and over 5000 gal. of water has to be handled per minute.

### CANADA

#### BRITISH COLUMBIA

(Special Correspondence.)—During the week ended Sep-

tember 21 the Granby company smelted 26,683 tons of ore, a total for the year of 905,782 tons. Blister copper shipments for the week were 523,000 lb. The Mother Lode mine, of the British Columbia Copper Co., sent 8201 tons of ore to the smelter at Greenwood. The Panama, near Kaslo, has commenced shipping silver-lead ore. Ore production for the week from the Boundary, East Kootenai, Nelson, Rossland, Slocan, and Ainsworth districts was 52,666 tons, and for the year to date, 1,764,904 tons.

Spokane, September 26.

#### COBALT

During the quarter ended August 31 the Beaver Consolidated company did 964 ft. of development. Before more cross-cutting is done, it is intended to sink to 700-ft. depth. The credit balance is \$68,553, which will enable the payment of next dividend of 3%. The usual quarterly dividends of the Nipissing and La Rose have been declared, amounting to \$450,000 and \$187,500, respectively. During the week ended September 20 nine mines shipped 382 tons of ore, and six shipped 160,648 oz. of silver bullion. The newly formed British Canadian Smelting Co., which intends to erect a large plant at Chippewa, will treat ore from Cobalt. The annual report of the Kerr Lake company shows that its total revenue was \$1,044,417, and net profit \$769,175. Dividends paid totaled \$762,000, and the surplus August 31 was \$716,992. Ore reserves are estimated to contain 6,660,000 oz. of silver. Much more waste has to be handled than formerly.

#### PORCUPINE

At Sandy Falls, six miles northwest of the Hollinger mine, the Porcupine Power Co. has installed a hydro-electric plant for supplying power to the Porcupine district. The plant consists of two pairs of 43-in. turbines of 1700 hp. each, under 34-ft. head, coupled to two generators of 1500 hp. each, 25 cycle, 3 phase, 12,500 volt, running at 214 r.p.m. Foundations for a third unit have been prepared. Light and power are being supplied to the towns of Porcupine and South Porcupine, and the Hollinger, Dome, McEneaney, and Plenaurum mines. The North Dome mine is to be sunk to 250-ft. depth. The McEneaney is down 370 ft. On the 300-ft. level the lode is worth \$50 per ton. The Dennis claims have been sampled a third time. The Foley-O'Brien mine is to be unwatered for examination. Since it started operations, the Ray mine has cost the company about \$905,470. There is a good quantity of ore above the 200-ft. level.

#### MEXICO

##### CHIHUAHUA

A 99-year concession has been granted by the Mexican government to D. J. Spillane, of San Luis Potosi, which permits the use of 75,000 litres of water per second from the Santa Maria and Gallinas rivers for the generation of electric power. Plans of the hydraulic plant are to be submitted before May 1914, and work is to be started within 60 days of their approval. The power available at the junction of the rivers is about 40,000 hp. The height of the falls is 106 metres. It is said that a company formed in the United States has purchased the concession.

##### SONORA

(Special Correspondence.)—During August the Tigre Mining Co. milled 6130 tons of ore and cyanided 7478 tons of tailing. With the shipping ore produced, the total value of the output was \$146,023. Total costs were \$83,298, leaving the profits at \$62,725. Full details are not available on account of delay to mail service. At the mill and in transit are over two-months supply of ore and concentrate, owing to the fact that heavy rains have destroyed part of the mountain road between the river and mine. The river itself has been too high to ford for over a month. Combined with the movements of the rebel forces in the surrounding territory, freight arrangements have been upset during August and the early part of September.

Kansas City, Missouri, September 20.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

L. L. PATRICK is at the Palace.

F. A. HEINZE has been at Bingham.

J. A. BURGESS is at the St. Francis.

PHILIP BRADLEY has gone to Nevada.

S. M. WRIGHT was here during the week.

F. G. CLAPP is in the province of Quebec.

W. H. LUCE is here from Sterling, Colorado.

H. S. GRAVES was in San Francisco recently.

EDMUND JUESSEN has gone to Sierra county.

L. A. FRIEDMAN was at Salt Lake City recently.

J. GORDON HARDY has left El Paso for Scotland.

H. C. HOOVER is in the southern part of the state.

WHITMAN SYMMES has returned to Virginia City.

POPE YEATMAN was at Hayden and Ray recently.

G. B. VAN ARSDALE has been in town from Yuba City.

A. J. RALSTON has left for Japan on a pleasure trip.

EDWIN T. F. LEWIS has returned from Antofagasta, Chile.

J. STUART MCKAIG is now at Franklin Furnace, New Jersey.

S. E. BRETHERTON has returned from an extended trip in the East.

HENRY KRUMB has returned from his vacation to Salt Lake City.

R. B. STANFORD has returned to New Orleans from Central America.

J. H. RODGERS has returned to Seattle from the Stikine River district.

F. LEROI THURMOND is now assayer for Cliff Mining Co., Valdez, Alaska.

WILLARD S. MORSE was here during the week and has gone to Tacoma.

J. C. REMOND and H. WRIGHTON were in San Francisco during the week.

N. J. MARTIN was in town recently and has returned to Loomis, California.

HERBERT C. ENOS has been examining mines in Chihuahua and has gone to Durango.

A. L. SWEETSER is at San Juancito, Honduras, expecting to remain over the winter.

STUART RAWLINGS sailed on the *Peru* for Mazatlan, returning to San Dimas, Sinaloa.

A. H. JONES, superintendent for the Belmont Milling Co., was in the city during the week.

DORSEY HAGER was in San Francisco during the week and has returned to Los Angeles.

W. C. PHALEN is in San Francisco investigating the salt industry along San Francisco bay.

M. K. RODGERS passed through San Francisco on his way to Guanajuato by way of New York.

C. M. DERBY has resigned as manager of the dredging department of the Natomas Consolidated.

F. JULIUS FOHS has been engaged in professional work in the Black mountains of North Carolina.

RALPH STOKES has accepted a position on the staff of the Canadian Mining & Exploration Company.

E. M. HAMILTON is at the Nipissing mine, Cobalt, where he plans to remain until the end of the year.

MILLARD K. SHALER was married in Lawrence, Kansas, on October 2, and, with his bride, is returning to Brussels.

F. F. GROUT and E. K. SOPER have returned to Minneapolis from a field study of the clay resources of Minnesota.

L. S. CATES, general manager for the Ray Consolidated Copper Co., has returned to Ray from a short business trip to Globe.

LOUIS WRIGHT, consulting engineer for the Lewisohn properties, has just returned to El Paso after a week's visit to the Miami mine.

NORMAN CARMICHAEL, general manager for the Arizona Copper Co., has returned to Clifton after spending a day at the Miami and Inspiration Consolidated mines.

### LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco October 3.

Antimony.....	11-11½c	Quicksilver (flask).....	41.50
Electrolytic Copper.....	18-18½c	Tin.....	62-63½c
Pig Lead.....	5.35-6.30c	Spelter.....	84-85c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

### METAL PRICES

(By wire from New York.)

NEW YORK, October 3.—Copper quiet but firm; decline in Europe due to political disturbances scaring off buyers. Lead firm; demands fair. Spelter quiet; buyers not anxious; market easier on account of European importations. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Sept. 26.....	17.53	5.10	7.48	63½
" 27.....	17.53	5.10	7.48	63½

### SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan. ....	53.81	56.25	July .....	52.57	60.67
Feb. ....	52.23	59.06	Aug. ....	52.17	61.32
Mch. ....	52.76	58.37	Sept. ....	52.41	62.95
Apr. ....	52.32	59.20	Oct. ....	53.37	...
May ....	53.31	60.88	Nov. ....	55.77	...
June ....	53.04	61.29	Dec. ....	54.85	...

### COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	12.29	14.09	July .....	12.47	17.19
Feb. ....	12.26	14.08	Aug. ....	12.41	17.49
Mch. ....	12.14	14.68	Sept. ....	12.20	17.56
Apr. ....	12.02	15.74	Oct. ....	12.19	...
May ....	11.99	16.03	Nov. ....	12.61	...
June ....	12.39	17.23	Dec. ....	13.55	...

### COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1910.....	141,766,111	244,961,280
January 1911.....	122,030,195	230,264,280
January 1912.....	89,454,695	178,329,920
February ".....	66,280,643	153,820,800
March ".....	62,939,988	141,125,680
April ".....	62,367,557	137,806,000
May ".....	65,295,368	134,176,000
June ".....	49,615,643	117,801,600
July ".....	44,335,004	107,817,920
August ".....	50,281,280	113,285,760
September ".....	46,701,376	112,743,680

### UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
August .....	125,493,667	59,935,364	69,885,660
September .....	115,588,950	57,311,584	50,824,011
October .....	118,255,442	64,068,656	60,084,349
November .....	111,876,601	68,039,776	67,049,279
December .....	122,896,697	65,988,474	79,238,716

Total for 1911....	1,431,938,338	709,611,945	754,932,733
January 1912 .....	119,337,753	62,343,901	80,167,904
February .....	116,035,809	56,228,368	63,148,096
March .....	125,694,601	67,847,556	58,779,566
April .....	125,694,001	69,513,846	53,252,326
May .....	126,737,836	72,702,237	69,485,945
June .....	122,315,240	66,146,229	61,449,650
July .....	137,161,920	71,093,120	60,121,600
August .....	145,628,521	78,722,418	70,485,150

(Continued on Page 454)

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice or mining, milling, and smelting.

**W**ASTES of the past are daily being converted into the dividends of the present.

**M**INERAL WATER, the product of 732 springs, amounting to 63,923,119 gal., was sold in the United States in 1911. The average price per gallon was 10.7 cents.

**B**ELTING used at the Baku (Russia) oilfields is principally that made from camel's hair; leather, cotton, and rubber belting not standing the action of the oil so well.

**W**EIGHT of the atmosphere has been calculated as 5,000,000,000,000,000 tons, containing 3,850,000,000,000,000 tons of nitrogen and 1,150,000,000,000,000 of oxygen.

**M**XTURES of air and acetylene containing 3 to 8% of the latter gas are explosive. Explosive mixtures are thus readily found in pipes and in the external neighborhood of leaky joints.

**B**REAKAGE of cam-shafts and stems is often attributed to camming and jarring in the former, and crystallization in the latter case, and is still a subject of debate. As a rule, these breakages are fairly heavy in all stamp-mills.

**M**ANY ore deposits are so low grade that they cannot be mined today, but should be left in position, so that they can be mined in the future; as many ores, formerly too low grade to work at a profit, are now sources of wealth.

**W**ASTE of carbon in modern economy is almost staggering. "In mining coal in the United States," says C. L. Parsons, "probably one-third of the bituminous and one-half of the anthracite coal are left in the mines. Fully 80,000,000 tons of anthracite is now being left behind in mines each year, and it is estimated that since mining began in this country fully 2,000,000,000 tons of anthracite and 3,000,000,000 tons of bituminous coal have been left in the ground, under conditions which make future recovery highly impossible."

**T**HE Imperial steel works of Japan, at Wakamatsu, on the straits of Shimonoseki, a government institution, is doing a lot of work, although it has been run at a loss until recently. The 1910 output was 62,000 tons of rails; 5000 tons of railway accessories; 28,000 tons of sheets and plates; 58,000 tons of bars and shapes; 2000 tons of bolts, nuts, etc.; 3000 tons of crucible steel, tires, axles, etc.; and 6000 tons of wire rod. Iron ore smelted totaled 218,000 tons, and pig iron produced was 130,000 tons. About 7500 workmen and 2000 coolies are employed. Figures for 1911 are not available, but are expected to exceed those given.

**C**OAL converted into coke in the United States in 1911 amounted to 53,278,248 tons, yielding 35,551,248 tons of coke. The quantity of coal consumed in the manufacture of coke and by-product in retorts was 10,446,584 tons, yielding 7,847,845 tons of coke. By-products consisted of 33,274,861,000 ft. of surplus gas, 69,410,559 gal. of tar, 72,920,056 lb. of ammonium sulphate, 23,180,118 lb. of anhydrous ammonia, and 4,660,596 gal. of ammonia liquor. The value of the recoverable contents now being wasted of the coal made into coke in beehive ovens would, at prices obtaining in 1911, have been worth between \$35,000,000 and \$40,000,000. The quantity of boiler-horse-power obtainable from this source would be about 400,000 hp. per hour for every day of the year.

## Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

### GAS LEASE—ROYALTIES PAYABLE FROM ADJACENT WELLS

A gas lease providing for royalties and not specifying the number of wells to be drilled, requires the lessee to develop the land with reasonable diligence, and entitles the lessor, at least, to royalties on the gas taken by the lessee through wells on adjoining land.

*Culbertson v. Iola Portland Cement Co.*, (Kansas)  
125 Pac., 81. July 6, 1912.

### POSSESSION OF SURFACE AND MINERALS DISTINCT

A purchaser of mineral rights in land from one not shown to have been in possession was put on inquiry as to the rights of persons claiming under an unrecorded deed where it appeared that the land had been cultivated. Possession of land in which mineral lies may exist and be exercised of the mineral as distinct from the surface, or of the surface as distinct from the mineral.

*Sloss-Sheffield Steel & Iron Co. v. Taff* (Alabama),  
59 Southern, 658. June 29, 1912.

### DEED TO LAND CARRIES SUB-SURFACE RIGHTS

Where, at the time of a gift of coal land by a father to his son, there had been no severance of the title to the coal, and the son took actual and exclusive possession of the surface, such possession carried with it actual possession downward perpendicularly through the various strata so as to confer title to the coal on the son as against a subsequent grantee of the coal by the father.

*Greenwich Coal & Coke Co. v. Learn*, (Pennsylvania)  
83 Atlantic, 74. Jan. 2, 1912.

### ASSESSMENT WORK—FORFEITURE AND RE-LOCATION

Where a mining location was made in December 1905 and the locator ceased to do assessment work in the year 1908, without having done \$100 worth of labor during either 1907 or 1908, the claim became subject to re-location. The work of the first locator done in 1907 and 1908, having been of less value than \$100, the re-locator was not required to wait until the expiration of the year 1908 in order to make his re-location.

*Galbreath v. Simas*, 161 California, 303.

### AGRICULTURAL ENTRIES ON OIL AND GAS LANDS IN UTAH

Unreserved public lands of the United States in the state of Utah, which have been withdrawn or classified as oil lands, or are available for oil, shall be subject to appropriate entry under the homestead laws by actual settlers only, under the desert land law to the extent of 160 acres only, to selection by the state of Utah under Congressional grants and the Carey Act, to withdrawal under the Reclamation Act, and to disposition by the Secretary of the Interior under the law providing for sales of isolated tracts; reserving always to the United States the oil and gas rights in such lands, with the right to prospect and remove the same upon payment of damages to the agricultural patentee for actual injuries suffered by him.

Act of Congress, Approved August 24, 1912. (Not yet published.)

**GUATEMALA'S** mineral wealth is great, though but little explored as yet. In the northern part of the country, silver-lead ores occur, extending through to the frontiers of Honduras and Salvador. In the eastern part are gold placers, some of which are now being worked by American engineers. The gold belt extends along the entire frontier of Honduras, and rich ore is sometimes found. Silver ores in the province of Santa Rosa assay \$40 per ton. The Government is liberal in its dealings with miners, and foreigners who engage in mining receive all assistance possible.

## LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan. ....	4.48	4.43	July .....	4.50	4.71
Feb. ....	4.44	4.03	Aug. ....	4.50	4.54
Mch. ....	4.39	4.07	Sept. ....	4.48	5.00
Apr. ....	4.41	4.20	Oct. ....	4.27	...
May ....	4.37	4.20	Nov. ....	4.30	...
June ....	4.34	4.40	Dec. ....	4.45	...

## ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan. ....	5.45	6.42	July .....	5.70	7.12
Feb. ....	5.52	6.50	Aug. ....	5.95	6.96
Mch. ....	5.56	6.57	Sept. ....	5.86	7.45
Apr. ....	5.40	6.63	Oct. ....	6.10	...
May ....	5.35	6.68	Nov. ....	6.38	...
June ....	5.50	6.88	Dec. ....	6.30	...

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan. ....	44.60	43.75	July .....	48.00	43.00
Feb. ....	48.40	46.00	Aug. ....	50.00	42.50
Mch. ....	52.50	46.00	Sept. ....	47.50	42.12
Apr. ....	50.90	42.25	Oct. ....	46.12	...
May ....	46.50	41.75	Nov. ....	45.50	...
June ....	46.50	41.30	Dec. ....	44.50	...

## TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan. ....	41.25	42.53	July .....	42.40	44.25
Feb. ....	41.61	42.96	Aug. ....	43.32	45.80
Mch. ....	40.16	42.58	Sept. ....	39.75	48.64
Apr. ....	42.18	43.92	Oct. ....	41.18	...
May ....	43.11	46.05	Nov. ....	43.12	...
June ....	44.61	45.76	Dec. ....	44.65	...

## Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Helmann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, $\frac{1}{2}$ 100 lb. ....	\$0.75	\$1.00
Acid, sulphuric, com'l, 66°, carboy, $\frac{1}{2}$ 100 lb. ....	1.00	1.50

## EDITORIAL

**R**EHEARING of the case of the East Tintie Consolidated Company has been denied by the Interior Department, and a precedent is thus firmly established.

**M**ILITARY men claim that airships have made war impossible. Unnecessary would perhaps be the better word, since 13 aviators were killed during September.

**K**ELP deposits at Point Wilson, Washington, have been filed upon by a potash company. The old problem of what is a placer deposit will doubtless at once revive.

**B**ALTIMORE has become an important shipping point for oil. The export trade of the United States in refined mineral oil during the year ended June 30, 1911, was valued at \$92,098,000. Two new tank steamers, the German *Adorna*, of a capacity of 2,000,000 gallons, and a Brazilian ship of a capacity of 1,000,000 gallons will sail from Baltimore, and its place in the oil-carrying world will be correspondingly strengthened.

**C**OAL consumers in the Eastern states are troubled over a condition bordering on shortage due to lack of labor, shortage of cars, and higher prices prevailing in the West. Even the railroads feel the pressure, and a leading official ventures the opinion that coal prices will rise \$1.50 per ton at Albany in the course of next year. Private consumers near New York who have had their winter supply ordered since early in the summer have not yet been supplied.

**K**ANSAS now has a State School of Mines, which has begun work in temporary quarters at Weir City. To discourage endeavor is an ungrateful task, but it may well be questioned whether further additions to the already considerable number of poorly supported and attended state schools of mining are desirable. The local paper ingenuously remarks that the citizens of Weir City have incurred considerable expense in starting the school, but that hereafter it will draw its support from the state and national governments. The ideals which lead to the founding of state schools and universities should have a higher origin than the fount of appropriations.

**E**LSEWHERE we publish the data required by the new regulation of the Post Office Department, referred to editorially in our issue of September 21. Not the least interesting phase of the effects of the new law is the almost complete silence which daily journals have observed regarding it, a news item in the *Chicago Tribune* and our own editorial comment being the only references to it that came to our attention before the date fixed by law for making returns. It has become evident of recent years that daily journals have lost influence over public opinion with a growing general belief that their utterances are often distorted to suit the owner's ends. But the power to suppress news can never be shorn from them.

TO this issue Mr. T. A. Rickard contributes an account of the development of printing, and the growth of the technical journals, which will be of value to our readers. It is interesting to note that the oldest journal in the world, the *Peking Gazette*, suspended publication, in its original form, upon the abdication of the Manchu dynasty last year. This official record of the doings of the Peking court is known to have been published since the ninth century, though, like our own *Congressional Record*, it contained no news, being an official journal of the Government.

**L**EASING of public coal lands to private corporations is to be undertaken in Wyoming. The Owl Creek Coal Company has now leased for 30 years the right to mine coal from beneath 2480 acres of public coal land near Lander, at the rate of 6½ cents per ton for the coal mined during the first five years, and 8 cents per ton during the following five years, after which the company has preferential right of renewal for periods of five years to a total of 30 years. Further details will be found in the Washington correspondence, elsewhere in this issue. The United States Geological Survey has now classified and appraised coal lands in the Western states of an estimated value of over \$700,000,000 and the introduction of logical and effective methods of coal land development will react to benefit Western industry.

**C**OPPER producers' figures show an increase in domestic stocks of over 16,000,000 pounds during September, though, on the other hand, the mines at Bingham, Utah, and Ely, Nevada, remain idle, and the situation in the Balkan states has, at the time of going to press, passed beyond control. The situation is, therefore, somewhat complex. Whether the metal market will respond to the enforced curtailment of production by bidding copper to higher levels, whether the demand for munitions of war will create an added demand, or whether the European political unrest will cause a slackening of what is regarded as over-extended industrial activity is difficult to prophesy. Large blocks of shares in leading copper mines are held in France and the exchanges in Paris, Berlin, and London have been quick to reflect the parlous situation of Turkey. It is quite within the range of possibility that this month may see a sharp advance in the price of copper, though producers are doubtless sincere in their professed aversion to an increased price, which would inevitably be reflected in a slackened demand.

### A Wyoming Golconda

Wyoming is a celebrated state, through the activities of Messrs. Owen Wister, F. E. Warren, and others. Mr. Charles Martin, "one of the foremost citizens of Encampment," also contributes his mite, to which the *Centennial Post* devotes a two-column head on its front page. Mr. Martin is interested in the holdings of the American Mineral Development Company, in comparison with which he thinks the Camp Bird will eventually appear a mere toy. In response to an inquiry as to ore reserves he has given out this alluring statement: "Take your pencil; take the length of the vein—7000 feet—which is opened up; multiply it by 60—although the four veins are 63 feet wide—and then multiply this result by 1000, because there is an average depth of 1000 feet above the water-level of the Middle Fork or the Little Laramie; and you have 420,000,000 cubic feet.

"Divide this by 15 cubic feet to the ton and you have 28,000,000 tons. Understand now," emphasized Mr. Martin, "this is above water-level, and all oxidized ore. How much will be found below water-level and what the values will

be, in the sulphide ores, of course, is conjecture, although we all know it is the history of gold mines that they grow richer with depth.

"As above stated you have 28,000,000 tons, which it is my candid belief and judgment will show an average gold value of better than \$10 per ton; but suppose you estimate it at \$5 per ton and you will find it will give you the tremendous result of \$140,000,000.

"Oh, yes, I realize these figures are staggering; but nevertheless it is my judgment as a miner of many years experience that the American Mineral Development Company's holdings will with development stagger even the most credulous with its phenomenal values." We begin to stagger already.

### The Institute Meeting

Institute members everywhere will be gratified to learn that the differences of opinion which have existed among the members during the past year have been settled, and the way is now clear for constructive changes which will make the Institute more effective and bring the members more closely in touch with the society they constitute. On another page we give a brief telegraphic report of the proceedings at New York on Monday, and it is interesting to note that the action taken was substantially in accord with the suggestions made by the Los Angeles and San Francisco members, published in our issue of September 28. The Western members are now well informed in regard to the needs and possibilities of the Institute, and it is to be hoped that they may retain their interest. The formation of vigorous local sections, as nearly autonomous as possible, will do much to keep this interest alive, and their organization, should be encouraged. The local section at Spokane, largely through the efforts of its capable secretary, Mr. L. K. Armstrong, has done commendable work, and its example should be imitated.

The constructive program proposed by Mr. C. R. Corning, who as a member of the Committee of Five has given careful study to the financial and other problems of the Institute, is a commendable one upon the whole, though detailed comment must be reserved until the exact text of the proposed changes is available. But, in our opinion, over-legislation is undesirable, and it is neither necessary nor wise to incorporate into the constitution and by-laws of a society provisions in regard to management which may safely be left to the directors and council. These gentlemen are trustees for the members, and their actions should reflect the wishes of the members who are interested enough to become well informed on Institute affairs and to make their opinions known to the council. Whether delinquent members should be dropped at the end of four months or a year is a detail of business management which can well be left to the governing body to determine, since its action is more easily subject to change in correspondence with possible changed conditions. The appointment of a business manager for Institute affairs is unreservedly commendable. The larger part of the present activities of the Institute are those of a publishing house, and in these days of high cost of living the publishing house which can succeed without the careful attention of a business manager is indeed unusual. But what will awaken most general commendation among members is the creation of the office of secretary emeritus, as a recognition of the long and devoted service of the veteran secretary, Dr. Raymond. To his long term of unremitting effort the present standing of the Institute is in large part due, and the amendment only voices the sentiments of all the members of the Institute in acknowledging their debt to the greatest editor in the field of mining and metallurgy.

# The Newspaper

By T. A. RICKARD

On September 10, 1912, the greatest of all newspapers, *The Times*, published at London for a century and a quarter, celebrated its forty thousandth daily issue by giving its readers a compendium of special articles on printing and all that pertains thereto. Among the 60 pages of beautifully printed matter published on that day is to be found a history of printing and of the newspapers that grew therefrom, to develop into one of the great forces of civilization.

From this record we learn that the Chinese published books from wooden blocks as early as the year 922, and that Pi Shêng invented movable type centuries before it was first known in Europe. We are told that the lack of suitable ink delayed printing and that the preparation of such ink gave the Chinese their early preëminence. It is a fact that the invention of an ink made from a mixture of lamp-black and oil, by Jan van Eyck, in Holland, in the early part of the fifteenth century, was the immediate precursor of the adoption of printing in western Europe. Picture-printing from wooden blocks preceded text-printing by about two centuries; then came the engraving of lettering or text on blocks, for block-printing had some of the advantages of stereotype plates. It was the need of the schoolboy that brought the craft into existence, the first books printed, in Holland, being Donatuses or school-books. The invention of type-printing is usually accorded to Johann Gutenberg, but he seems to have been largely a composite hero, and must share the honor with Johann Fust and Peter Schoeffer, the former the business-man and the latter the type-cutter to whom the first success is to be credited. The traditional date is 1440, with Mainz as the place, but earlier printing is recorded at Strassburg, also by Gutenberg, who in turn was preceded by the printing of school-books in Holland. However, the first fully authenticated work in Europe was the printing of Letters of Indulgence for Pope Nicholas V in 1454 by Gutenberg, Fust, and Schoeffer at Mainz. Thus the art of printing at its beginning, as often since, was prostituted to a miserable purpose, for these Papal Letters of Indulgence are symptomatic of an ignorance and superstition worthy of the dark ages, then about to be punctuated by the Reformation. The first type was cut in wood, before tin, lead, and other alloys were found more suitable. Many will remember the old story of how Laurens Coster, once the employer of Gutenberg, first cut letters out of birch-bark and by inking them was enabled to stamp paper for the amusement of his children. When printing was invented, the finest vellum was being made in France and Italy, concurrently paper-mills were increasing, libraries and schools were multiplying, and the intellectual thought of Europe was about to break from the shackles of ecclesiasticism. Thus the times were ripe for the spread of recorded knowledge.

In 1501 the scholar Aldus Manutius, working at Venice, issued a series of classics in small octavo printed in a new type simulating the handwriting then in vogue. Thus originated *italics*, from Italy, where Aldus invented the type. This fashion dominated the sixteenth century, but it yielded to the Roman characters soon thereafter. "A matter of unmixed rejoicing," says the chronicler in *The Times*. Undoubtedly, for even to this day the sympathetic editor will delete the underlining that in manuscript calls for italics, for he knows what a nuisance it is to the compositor, who has to go out of his way to pick such type out of a special font, and return it after use.

Printing is responsible for the newspaper. The news-

paper was developed from the ballads of battles, murders, and other notable events that were sold and sung in the streets at the close of the sixteenth century. Then came the news-letters prepared by 'intelligencers' hired by statesmen and others requiring to be kept informed concerning current events. These news-letters grew, in the time of the Stuart kings, to 'relations,' or pamphlets relating in detail the big news of the day. With the slow growth of the postal service the exchange of printed news-letters was commenced across the Channel, from England to France and Holland. But regular periodicals were slow to evolve.

Printing, like coinage, was a right of the Crown; no printing was legal without the sanction of a licenser appointed by the King. Regulations on the subject were strict. Hence printed news was first issued in Italy, France, and Spain, as is suggested by words still surviving, such as 'novel' and 'gazette.' Translations from 'relations' published in Dutch or German had vogue long before the first newspaper appeared in England, in 1665.

Previous to the newspaper, the printed medium of publicity was the 'pamphlet,' from *pampe*, a fourteenth century French word for a small book of parchment leaves. The 'coranto' (an Italian word) or serial pamphlet was the sequel to the 'avis' (from the French *avis*) and 'relation.' Then came the newsbook or 'diurnall' (hence 'journal'); the first English periodical of domestic news being *The Perfect Diurnall*, which was published from 1641 to 1655. The 'intelligencers' and 'mercuries' that flourished during the days of the Great Rebellion were political diatribes issued for party purposes. The most famous were those of Henry Walker, Cromwell's journalist, who was placed in the pillory by the followers of Charles I.

Early in its development, and before the occasional pamphlet had become a daily newspaper, the Press incurred the animosity of those in power. The Star Chamber, Cromwell, James II, each in turn, whether Puritan or Cavalier, Whig or Tory, suppressed the Press whenever the discussion of current events became too free or too incisive. Charles II appointed Sir Robert L'Estrange as censor, under the title of 'Surveyor of the Presses,' in 1662. That "brave and upright English gentleman" was "intolerant both in politics and religion," as the chronicler allows. Hence his fitness to be a newspaper moderator! He it was who fastened the term Whig on "circulators of fraudulent literature." He, it is recorded, was actually the first Tory. We believe it. His notion of the function of the newspaper is wholly in character. In the first place, he proceeded to run a paper of his own, *The Intelligencer*, which appeared first in 1663. In the first issue he confessed his objection to 'newsbooks' of any kind, asserting: "A public mercury should never have my vote, because I think it makes the multitude too familiar with the actions and counsels of their superiors, and gives them not only an itch, but a kind of colourable right and license to be meddling with the Government." How delicious! Thank the Lord the idea that there must be mystery in government and secrecy in industry has been smashed to the four winds since the day when this cavalier had the insolence to express such a sentiment. The idea still survives in musty corners, among tyrannic governors and reactionary managers, but it has been stultified so thoroughly as no longer to command respect.

In 1665 L'Estrange lost his right to be sole journalist. The Court had fled to Oxford and there printed a bi-weekly periodical called *The Oxford Gazette*. L'Estrange was pensioned. On February 6, 1666, *The Oxford Gazette* became *The London Gazette*, which still survives as the authorized record of official events. As first published it was "a bi-weekly printed in two columns on both sides of half a sheet of folio." Its appearance marked the commence-

ment of the newspaper era and an end to the period of pamphlets. In 1680 the *Gazette* published a proclamation against the unlicensed press, which, of course, were guilty of a breach of the Royal prerogative. The immediate result was to stimulate a recrudescence of scurrilous pamphleteering. The first unlicensed paper was that of Benjamin Harris, who had to flee to America, and, on September 25, 1690, at Boston, published the first American newspaper. It was christened *Publick Occurrences*, and appears to have been worthy of the later ideals of Pulitzer and Hearst, being suppressed by the Governor of the colony for marketing a revolting accusation against Louis XIV. who, for the moment, was a friend of the British Government. In 1695 the press in England won its freedom at last; the Royal prerogative of printing was no longer claimed and the Parliamentary ban on the publication in print of the legislative proceedings was no longer enforced. *The London Gazette* still remained the leading newspaper and set the fashion to its juniors, but it was already being relegated to that background in which it is now comfortably established. The founding of the Royal Society by Charles II and his scientific friends led to the publication, in 1681, of an illustrated periodical, called *Philosophical Collections*, by Moses Pitt. This may be claimed as the first example of technical journalism.

It is a curious fact that the early history of *The Times* is associated with that of the United States. The founder, John Walter, was a London merchant who was ruined by underwriting ships during the War of Independence. In order to retrieve his fortunes he started a printing business, receiving the support of his friends and his creditors, to whom he had proved himself an honorable man. He had a scheme for using type consisting of whole words or syllables instead of single letters, and it was to use this logographic printing that he started a newspaper called *The Daily Universal Register*, on January 1, 1785. Three years later, in the year when the independence of the States was formally recognized, he changed the name of his paper to *The Times*. He reduced the number of logotypes to 1500, and used this method for three or four years, when he was compelled by his compositors and the printing trade generally to abandon his pet scheme. His paper prospered. After him came other Walters, worthy men who maintained a fine tradition from generation to generation. Even to this day, when the family is no longer so dominant in the management, at least two Walters are to be found on the staff of *The Times*. But it to its editors that the paper owes its fame. John Delane it was who first gave this British newspaper a worldwide influence, and other editors, such as George E. Buckle, who retired recently, maintained the high standard of intellectual honesty that has kept *The Times* in the primacy of journalism. In its forty-thousandth number it gives that history of printing from which I have quoted, but the editor of *The Times* can fitly say: *Si monumentum requiris, circumspice*. No more appropriate monument to the art of printing need be instanced than *The Times* itself. In behalf of the oldest mining paper in America I offer my hearty felicitations, with the wish that the leading newspaper in our language may long continue to set a good example and wield a beneficent influence by means of that art and that craft of which for 125 years it has been a leading exponent.

ACCORDING to statistics published by *Moniteur de Pétrole Roumain*, the production of crude petroleum in Roumania during the first six months of the calendar year 1912 was 864,901 tons, or 171,548 tons more than during the corresponding period of last year. Moreover, this increase might have been further augmented had transportation facilities been better. There not being sufficient cars available, a number of wells were obliged to shut down.

## The Grain of Igneous Rocks

By A. C. LANE

"Some rocks are coarse grained and some fine grained, just as grocers sell coarse and fine granulated sugar, but it is not at all necessary that all the different minerals that make up a rock should be of the same grain. This is not generally true. It is also quite possible that in comparing different parts of one rock mass, one mineral may be coarser, another finer. Whether this is so is a matter of observation. In any precise work the grain of one mineral must be considered at a time. Still it is a matter of common observation that some rocks like pegmatites have a generally coarse effect, others mineralogically alike, aplites say, are generally much finer grained.

The coarseness of grain of a given mineral may be determined by the linear dimensions of its crystals or by the areas covered by them in cross-section. Practically, it is generally more rapid and convenient to compare linear size, though the areas appear to vary more directly with the slowness of cooling. The grain of a mineral may then be determined by taking the average of breadths of the grains. I have sometimes used the average of five of the grains (making sure of full-sized ones and not working on clipped corners, by taking the largest within a given area large enough to include numerous grains, like the field of view of the microscope, or a square centimetre, etc.). Another way of measuring the grain is by varying magnification. If one section, magnified five diameters, appears as coarse as another, we may say its grain is one-fifth as coarse. In the Isle Royale section most of the work was done with a micrometer eye-piece, one of whose divisions was about equal to 1/30 mm. So I took three observations, for by adding them and pointing off two places the result is the average dimension in millimetres.

The grain of the rock may be regarded as the grain of characteristic and dominant constituent minerals. If it be studied with relation to the margin of an igneous rock it is important that the mineral should be one which formed after the fluid rock magma came to rest. The last formed constituent is generally that which conforms more closely to the laws of cooling, for (1) heat given out by chemical rearrangement is less, and (2) even its own latent heat of crystallization is taken up largely by pre-existing minerals and thus disturbs the simple cooling effect less; (3) the abundance of granules already present tends to prevent undercooling and brings on crystallization promptly, as fast as the temperature drops so that it is possible; (4) initial irregularities in temperature are more likely to have been smoothed out. My most important and interesting results have been obtained on the augite which is the last formed essential ingredient of many of the traps—those that run about 48% SiO<sub>2</sub> and 10% CaO, such as are very common in the Keweenaw series. It is the cement or mesostasis.

DETAILS of the work of the Transvaal mines for the first half of the current year are as under:

Stamps at work .....	10,055
Tube-mills at work .....	263
Tonnage crushed .....	12,847.652
Total yield .....	\$92,625,600
Yield per ton .....	\$7.08
Costs per ton .....	\$4.56
Profits per ton .....	\$2.52
Total working profit .....	\$30,948,000

About 63% of the gold recovered by Rand mines is caught on the plates.

\*Excerpt from the Annual Report of the Board of Geological and Biological Society of Michigan.

†Rosival (Verh. Wien Geol. Reichs-Anst., XXXII, 1898, p. 143) has demonstrated that volumes are proportional to linear measurements of mineral grains in section, as A. N. Winchell has called to my attention.

# Possibilities of the Mother Lode in Depth

By W. H. STORMS

Obviously every mine must depend for its success upon the conditions, geological, physical, and economic, obtaining within itself. While no two mines are alike, though similar, yet, by comparison of various mines much can be learned that is of interest, and in this way deductions from the observed facts can more safely be made.

If there were but one or two mines developed throughout the length of the Mother Lode, it would scarcely be safe to assume that these were indicative of the possibilities of the other undeveloped mines on the Lode, as the examples might be unfortunately chosen; for at several places on the Lode large sums of money have been spent in a fruitless and, I may say, in some instances, hopeless search for profitable ore. While it is not given to anyone, no matter how experienced, to see far into

Since certain physical conditions are known to be the accompaniment of valuable mines, the pertinent question is, what are these desirable conditions? Briefly, every profitable ore-shoot outcropping on the Mother Lode is situated either on a smooth unbroken hill, or on a nearly level tract of land, not cut by transverse ravines. In considering this phenomenon it is necessary to distinguish between ore-shoot and mine, for a mine may have several ore-shoots. It has been noted by myself and others that on the Mother Lode no ore-shoot, *at the surface*, crosses a gulch or depression, though an ore-shoot outcropping on a hill may, in its downward trend along the plane of the fissure in which it occurs, pass *in depth* beneath a neighboring ravine. The only explanation I have to offer for this phenomenon is that gulches, ravines, and depressions at the surface are usually the physical expression of geological disturbances beneath the surface. The primary cause may have been a fault or a fold, or it may be due to the fact that the rocks have been somewhat softened by crushing as a result of compressive stress.

Thus far, throughout the length of the Mother Lode, no very profitable mine has been developed in a locality where the surface is cut into a series of short ridges by ravines crossing the strike of the Lode. It is needless to mention the mines on the Mother Lode that are characterized by the favorable indications referred to, as every largely profitable property, beginning with the Princeton in Mariposa county, and as far north as the Union mine in El-

KEYSTONE MINE, AMADOR.

the ground, yet observing geologists and mining engineers have learned by experience that on the Mother Lode there are points where the hope of developing a profitable mine is slender, to say the least, while in other places the conditions are such as to invite exploration with a reasonable probability of success in the developing of a valuable mine. In this the ore deposits of the Mother Lode are peculiar. The generally recognized limitations of the extent of the Mother Lode are from the vicinity of the old village of Bridgeport, in Mariposa county, in a northwest direction to near the northern boundary of Eldorado county, a distance of about 120 miles.

If, in traveling the length of this great Lode, it is found that every mine that has been largely profitable exhibits a noticeable set of conditions, and it is also observed that every unprofitable property is environed by another set of conditions opposed to and unlike the first, it must be concluded, whether willingly or not, that in undeveloped ground where the conditions which have been recognized as unfortunate are present, the proposal to undertake the development of this piece of ground would naturally be looked upon as extremely risky, or at any rate, as involving a risk greater than might be anticipated in a locality where the physical conditions were of that type known to be constantly associated with those mines which have been profitable.

dorado county, without exception, is situated on a hill or on a flat, uncut by gulches or transverse depressions; or, if such occur, the ore-shoots lie between them. Careful investigation fails to find a profitable mine in a locality where the Lode passes through a series of short broken hills. Ore-shoots may, and do, occur in these localities, but they are short and generally do not justify the extensive work and equipment necessary to their development and exploration.

For years an effort has been made to determine, if possible, whether there is any uniformity or system in the distribution of ore-shoots in the great fissures of the Lode, but I have been unable thus far to discover any regularity whatever in the occurrence of bodies of workable ore. However, it may be said that in most of the mines the profitable ore was first found some distance below the surface, though there are several noticeable exceptions. Generally the zone of profitable ore was entered at 100 to 600 ft. below the surface; and in one instance—that of the main orebody of the Central Eureka mine, near Sutter Creek—the shaft was sunk in the fissure to a depth of 1000 ft. before workable ore was found. At the Union mine in Eldorado county the first pay-shoot occurred at the surface, though there were several shoots down to the 1700-ft. level. At the Plymouth Consolidated mines, in Amador county, the first ore-shoot outcropped at the sur-

face, but within 100 ft. it became poor again, the shaft passing through an impoverished zone to a depth of about 600 ft., where rich ore was found that continued to a depth of 1600 ft., the shoot producing, it is reported, \$10,000,000. The depth of the shaft is 1700 ft., the lowest level being at 1600 ft. A disastrous fire in the lower levels about 1889 caused the suspension of all operations in these mines for many years. This famous property is now being reopened by Bewick, Moreing & Co. of London.

At the Gover mine of the Fremont Consolidated company ore occurred at the surface and extended to the present lowest level, 1650 ft. (1280 vertical). Sinking is in progress in the inclined shaft. The Fremont Consolidated has produced in excess of \$5,000,000. The property has had a varied career, having been repeatedly closed in its earlier history, never having been properly equipped before coming under the present management.

The Bunker Hill property, near Amador City, has also had an interesting career. For years it was opened and closed by one company after another, none of which did well, assessments being far more conspicuous than dividends, until about eight years ago, when the present manager took control and drove a cross-cut into the hanging wall and there found a vein not previously known to exist. Fortunately, he cut the vein in good ore, and the Bunker Hill mine soon thereafter became one of the important producers, and one of the most profitable on the Mother Lode, and still continues to be. The mine is about 2000 ft. deep, with every indication of continuing to very much greater depth.

The Keystone mine at Amador City was among the first quartz mines worked in California. It was first known as the Ministers mine, being owned by a number of clergymen, but they were unable to make it pay. It passed from one to another with varying fortune, until it came into the ownership of James McDonald, who worked it successfully for many years, the mine producing, according to what is considered competent authority, upward of \$17,000,000. The greater portion of this large sum came from the veins in the black clay-slates. The shaft reached a depth of 1575 ft. (1200 ft. vertical), and all who know this famous old property agree that it should be explored to greater depth. Sinking is now in progress.

The Lincoln mine at Sutter Creek has a record of \$2,500,000, paid from the surface to a depth of 350 ft., but at that level the vein was intersected by a fault, beneath which the vein has apparently not been rediscovered, although extensive workings have been opened to a depth of 2000 ft. The fault in the Lincoln mine is the most extensive that has thus far been discovered on the Mother Lode.

The Wildman-Mahoney mine adjoins the Lincoln on the south. In this ground the vein splits into two branches, one of which passes into the Lincoln ground. On the Mahoney, and on the north end of the Wildman, the ore came to the surface, where it was worked in large open-cuts. This zone extended to a depth of 300 to 400 ft. Between this and the lowest level, at 1400 ft. (1200 ft. vertical), were found several shoots or masses of ore, some of them of large size, though for most part low grade. In the south end of the 1400-ft. level, it is stated, on what I believe to be good authority, that there is a mass of low-grade ore 170 ft. in width, though its other dimensions are unknown. This property is said to have produced \$3,500,000, and if properly equipped to operate on a large scale would no doubt prove to be valuable at greater depth.

The Eureka Consolidated mine at Sutter Creek has been the richest mine on the Mother Lode, according to report. It was discovered in 1850, and soon thereafter came into the possession of Alvinza Hayward, who undertook its development, but who for some time met with disappointment, as the ore within 200 ft. of the surface was unprofitable (at that time). However, he persevered, and at about 200 ft. in depth the ore improved and he was soon working the most profitable mine in the state. The ore

continued to a depth of about 1750 ft., the single shoot producing \$20,000,000. The deepest workings in this property are at 2200 ft., this being at the bottom of a 200-ft. winze sunk from the 2000-ft. level. The hanging wall of this vein is massive greenstone (tuff); the foot-wall is clay-slate. The ore-shoot was 500 to 600 ft. long at the 1100-ft. level. It is reported that the ore down to 500 ft. did not mill over \$10 per ton, though much of that below the 500-ft. level averaged \$30 per ton and over.

The Central Eureka mine adjoins the last mentioned property on the south. In its early history it was known as the Summit mine. Near the north end of the mine was found a small shoot of ore which in its downward trend pitched into the adjoining Badger claim of the Eureka Consolidated company. It did not go to great depth, according to report. (See Tenth Report, State Mineralogist of California, p. 104). This ore was low-grade at the surface, but at 165 ft. was worth \$25 per ton. The vein became so small in depth that it was finally abandoned. After an idleness of many years, the property was reopened by an incorporated company known as the Central Eureka Gold Mining Co., about 1894. A shaft was started several hundred feet south of the workings above referred to, and this shaft was sunk in the fissure to a depth of 1000 ft. or more, before any workable ore was found. At about the depth mentioned, three short and narrow shoots of ore were cut, but at the 1200-ft. level these shoots were found to have become longer, the ends overlapping, and from that level downward, to below 2400 ft., they constituted a large and profitable body of ore, from which substantial dividends were paid for several years. The end-lines of this property, as originally located, were convergent in the direction of dip, thus limiting the area and extent of operations, but the company has recently acquired additional territory adjacent to the original holdings and has resumed operation on a large scale.

Joining the Central on the south is the South Eureka, now one of the noted mines of the Mother Lode—noted for the reason that after years of an unprofitable existence, and the levy of 58 consecutive assessments, a fortunate discovery was made of a valuable body of ore. This discovery was made in a cross-cut driven west on the 2700-ft. level and at a distance of about 200 ft. west of the shaft in order to secure filling for the stopes. Development work was at once undertaken and has been successfully continued until the present level after level being opened through cross-cuts driven from higher levels, these being started in the vicinity of the shaft. The extent of this shoot of ore has not yet been fully determined. It may go to the surface, though should it be found to do so it will prove the anomaly of the Mother Lode. One important fact in this connection points a lesson. During the term of management of the late J. F. Parks, he caused a cross-cut to be driven west from the main workings at the 500-ft. level. This cross-cut passed through a fissure in the clay-slate which was characteristic of the Mother Lode, but which at that point contained no ore. No lateral development was undertaken. The lesson to be learned from this circumstance is that ore-shoots are not without limitations, either as to length, height, or depth. In Mother Lode mines, as elsewhere, it is quite possible to drive levels above and beneath ore and to sink or raise beyond their horizontal limits, thus surrounding the shoot in the plane of the vein without disclosing the presence of profitable ore. A manager who cross-cuts and finds a fissure which at the place of intersection shows no ore, but which fissure is otherwise of promising appearance, is fully justified in driving, sinking, and raising in the fissure in search of a shoot of ore. Indeed, in my opinion, it is a serious mistake to fail to do so. Both the South Eureka and the Bunker Hill mines are unusual in that their ore-shoots are being developed from great depth upward the South Eureka from 2850 ft., the Bunker Hill from about 1900 ft. Ordinarily the development of a mine proceeds from the surface downward.

The Oneida mine is between the South Eureka and the Kennedy mines and has recently been acquired by the former company. The Oneida was extensively worked in early days, having been discovered in 1851. J. Ross Browne reported ('Mineral Resources of the United States West of the Rocky Mountains, 1868,' pp. 74-75) that the ore-shoot was 300 ft. long at the surface, and 400 ft. long at a depth of 400 ft., and that the average yield was \$17.50 per ton. The mine has seen several periods of prosperity and of idleness, and although not at present in operation, it is highly probable that the Oneida mine will still yield a large amount of gold, as the South Eureka company will undoubtedly drive its levels southward into the Oneida ground, and I anticipate with satisfactory results, for the reason that there are two or more veins of very promising appearance on which little or no development has been done. In this property, as in the others mentioned, the ore-shoots were not continuous in depth, but succeeded each other, to the lowest level, about 2200 ft. from the surface.

The Kennedy mine is one of the most noted gold mines of the world, not because of its richness, but from the simple fact that its management has been sufficiently progressive to sink the shafts through barren or unprofitable zones, after leaving those of largely profitable ore at higher levels, until these shafts have reached a depth greater than has been attained in any other gold mine in America. The present lowest level is 3450 ft. vertically below the collar of the main shaft, which is about 150 to 200 ft. lower than the outcrop of the vein on the hilltop. The main shaft has a present depth of 3654 ft. The result of this enterprise on the part of the Kennedy company, which, as indicated above, has with the other mines of the Mother Lode seen its dark days, has been to demonstrate not only that the fissures of this great lode persist to great depth, but that ore as profitable as ever was found in the mine at higher levels, has been developed in the lowest workings, at depths ranging from 3000 to 3450 ft. vertically below the surface (equivalent to about 4500 ft. on the dip of the vein). As previously stated, the Kennedy mine has had its vicissitudes. In its early history, during the sixties, the work was confined to that portion of the vein within 700 ft. of the surface. A quartz outcrop extends along the summit of the hill, marking the course of the vein, but this outcropping quartz is poor in gold and may still be seen in place. Somewhat deeper, however, good ore was found, and the early miners exploited the vein to a depth ranging from 300 to 700 ft., the former depth being near the North inclined shaft, the other near the South shaft. At these depths, and along a line connecting them, the quartz disappeared, only a fissure filled with gouge remaining. This fissure was strong, and continued in its course, both longitudinally and in depth. At 950 ft. in the South shaft, quartz again appeared in the fissures and continued for many hundreds of feet, forming a very valuable shoot of ore. Near the North shaft the quartz did not reappear in the vein until a depth of 1400 ft. had been reached, but from that level it continued downward for several hundred feet. There were two distinct ore-shoots in this portion of the mine in which there was a marked dissimilarity, though both were largely profitable. In the vicinity of the 2000-ft. level the condition of the mine was far from satisfactory. There was always some ore, but much of it was too low in value to meet the cost of mining and milling it. However, on the 2100-ft. level a vein was found which was a great surprise, as it came from the westward, from the foot-wall greenstone, in which direction nothing was expected. This vein proved to be profitable, and was perhaps the salvation of the mine, as it gave the company the much-needed courage as well as the means to continue the exploration of the great vein at still greater depth. Each year the workings were advanced to increasingly greater depth, the zone of impoverishment being at length passed, when it was found that below 2500 ft. the ore was again quite as good as that on any level above. The fact that the monthly output of the Kennedy mine with 100 stamps is nearly \$100,000, all

ore coming from below 2500 ft. vertical depth, is far more significant than any other argument that can be advanced in favor of deep mining on the Mother Lode of California.

The Argonaut mine joins the Kennedy on the south and is similar to it geologically and otherwise. The upper part of the main vein was not profitable in this mine above 400 ft. from the surface, but from that level downward for 1000 ft. or more the mine paid handsomely; but like its neighbor, the Kennedy, it had its zones of low-grade ore and through these the workings had to be driven, in depth as well as horizontally. At present the Argonaut is working a splendid body of ore in the vicinity of the 3300-ft. level (inclined depth), being the next deepest mine to the Kennedy on the Mother Lode.

The Gwin mine, in Calaveras county, is one of the most interesting of the Mother Lode properties, having produced several millions of dollars. The statement is made in the sixth report of the State Mineralogist of California, page 32, that the value of the ore in the early history of the Gwin mine was \$8 per ton in free gold, besides which there was about 2% sulphides worth \$100 per ton. The first ore-shoot discovered in the mine outcropped at the surface, and was worked to a depth of about 1500 ft. The second shoot was discovered while driving north on the 1200-ft. level, and proved to be a more important ore-body than the first. It seems, from what can be learned of the early history of the mine, that the management was, if not incompetent, at least improvident, and after a

KENNEDY MINE.

number of years of successful operation the mine was closed and remained idle for a long time, being reopened in 1892, when a vertical shaft was sunk to reach the vein below the old workings. For several years this enterprise was successful after reaching the vein, but in time, like the others, a zone of ore too low in grade to be workable, was entered, and the struggle for existence began which ended in the mine being closed indefinitely, notwithstanding a decided improvement in the value of the ore in the lowest level, at 2650 ft. vertically below the surface. It is my belief that the Gwin mine, with deeper development, will again become a valuable mine.

One of the most famous mines of California in the early days, and remembered still for its large output, was the Princeton, in Mariposa county. In many respects the Princeton resembles the Plymouth Consolidated mine, the Gwin, and also the vein in the South Eureka which has brought fame to that property within recent years. The Princeton vein occurs in a ridge of clay-slate, striking northwest. On the highest part of the ridge the vein outcropped for several hundred feet, but the ore was of only moderate grade, too low to afford a profit in those early days. At a depth of 100 to 150 ft., however, the ore was found to be much improved, and from that level to a depth of 600 ft. the Princeton output, according to official report, was over \$4,000,000. The work was not carried far below the zone of profitable ore at that time, but the levels were extended some distance beyond it. The mine was closed and remained idle for many years, but was reopened in 1900 and fully equipped with hoisting and milling machinery. Since that time the output of the

Princeton mine has been swelled by a sum in excess of \$1,370,000, making a total output considerably above \$7,000,000. The operations of the past ten years have shown the presence of much good ore, which has occurred here and there throughout the mine, but the average grade has been disappointing, so much so that the mine was closed, though, as it appears, not by unanimous consent of all interested. The Princeton vein possesses to a marked degree many of the peculiarities of Mother Lode mines. It occupies a fissure of great persistence, both of horizontal and vertical extent; there are occasional branches into the walls, a feature quite common in these mines; it has its zones of rich ore and those that are poor; a gouge is commonly present on one wall or the other, and there are many minutiae of its appearance which stamp it as a fissure of the Mother Lode series. That which appeals to me most strongly is the unbroken continuity of the vein on the lowest (1600-ft.) level. Here the vein is 6 to 8 ft. wide for a distance of 1500 ft., an unmistakable evidence of the strength and probable continuity of the vein. The depth reached in the lowest workings, 1600 ft., is almost shallow as compared with the workings of several of the most successful mines of Amador county. This is only 1250 ft. vertically below the surface at the bottom of the main shaft, which was stopped at 1660 ft. Comparing this with the Kennedy's lowest working level at 3450 ft. vertically, it is seen that the Princeton is scarcely more than one-third as deep as the former.

In reviewing the facts here presented, I think the following conclusions may safely be deduced:

1. All of the profitable mines of the Mother Lode of California have zones of good ore, and zones that were too low in grade to be workable, and that these zones are not uniformly distributed.

2. There is no great difference in the elevation of the collars of the shafts of the mines mentioned, all occurring at from 1100 to 1600 ft. above sea-level, with the exception of the Princeton, which is over 2250 ft. above the sea, or from 650 to 1000 ft. higher than the other great mines of the Mother Lode.

3. The upper zone of rich ore has been found to occur at any level between the surface and 600 ft. (in one instance, at the Central Eureka, at 1000 ft.), but there seems to have been established no definite depth at which rich ore has been replaced by that which is poor, nor at what level poor ore may be expected to be replaced by that which is rich. In fact, it has been demonstrated that good ore occurs at all depths between the surface and a vertical depth of at least 3450 ft., as proved in the Kennedy mine.

4. Proper geologic conditions seem to be more important than all other considerations, and where these are present there is every reason to anticipate the recurrence of rich ore in the fissure to a depth as great as it lies within human possibility and mechanical means to reach.

5. A mine having once been profitable may be expected to become so again in depth (provided the vein be not lost by faulting as at the Lincoln mine), as instanced by the development of nearly every important mine on the Lode.

## Iron Mining in Chile

The budget of Chile provides for an expenditure of ₧100,000, to be used in continuing the work of mapping out the iron deposits of the Republic, some work having already been done in the province of Coquimbo in 1911. In Coquimbo there are five groups of iron deposits, situated to the north of La Serena, known as Maitencillo, El Trigo, El Romeral, Las Escobas, and Los Hornos. These five groups are estimated to contain 200,000,000 tons of iron ore. Iron deposits are also found in Atacama, and in the department of Vallenar and Freirina. A conservative estimate of the ore contained in these is 30,000,000 tons. Investigations are also being made of the iron resources of Antofagasta, which are known to be considerable.—*Pan-American Union*.

## Gold Mining in the Philippines

The Luzon Gold Co. is engaged in placer-mining operations in the hitherto almost unexplored region lying along the Umiral and Angelo rivers partly in each of the three provinces of Tayabas, Nueva Ecija, and Rizal, according to the *Philippines Free Press*. The Angelo river is a branch of the Umiral, which empties into the Pacific ocean at Dingalan bay, about eighty miles to the north of the port of Mauban. The ground on the Umiral river below the mouth of the Oyongan is controlled by Australian people, who were interested in the project by R. W. and C. D. Squires, of Manila, and who are constructing a dredge. The ground has been prospected and the average value has been estimated at 35c. per yard. The returns of the Colorado Mining Co., operating a 20-stamp mill at Aroroy, Masbate, are said to have been satisfactory during the past eight months.

The most important project in Paracale at the present time is the Gumaus dredge, the construction of which was begun some months ago on the Gumaus river under the direction of H. Patterson, representing the New York Engineering Co. The dredge will be in operation soon. The Philippine Exploration Co., owning this property, expects to handle 90,000 cu. yd. of earth per month with the new dredge, and the output of bullion should be above ₧50,000 per month.

The old Stanley dredge, which has been idle for two years, has been taken over by a new local syndicate known as the Maximall Gold Dredging Co. The hull has been thoroughly overhauled and found to be in fair condition, and the company expects to begin operations in October with F. W. Pearson as dredgemaster.

The Australian syndicate, which is operating the old Paracale dredge on the Paracale river, has two dredges under construction, both of which will be operated in the Paracale river basin. The first should be completed by the end of the present year and the other a few months later. The combined capacity of the two dredges, it is claimed, will be 100,000 cu. yd. per month. The old Risdon dredge on the Maliguit river under the supervision of John A. Bruce, is still producing regularly about ₧11,000 per month. Judge Frank B. Ingersoll and A. J. McDonald are planning to place a 5½-cu. ft. dredge of the close-connected type on the Maliguit river in addition to the old one now operating. Several of the Benguet properties, including the Headwaters with its 10-stamp mill, are operating steadily. It is stated that a hydraulic plant will be put on some claims in Surigas by the Surigas Gold Mining Company.

SYRIA, besides being rich in land, is also reputed to be rich in minerals. Gold, silver, iron, lead, and almost all the important metals are found; also coal, bitumen, and petroleum, but there are no expert mineralogists in this country to investigate them. To extract these metals it is necessary to obtain a license from the Government, for which a special tax is paid, according to the nature of the metal looked for. This tax varies from \$243 to \$973, in proportion to the area of land to be excavated, and for every 10,000 square metres an extra tax of 10 piasters (35c.) is taken. Where metals are found, 5 to 20% of the total goes to the Government treasury. A native company was formed this year to search for minerals and purchase lands supposed to contain them. A German engineer was employed, lands were bought at Ajloon, a town 50 miles south of Damascus, and a concession was obtained for the extraction of metals, as well as phosphates, which are abundant in that district. An English company has likewise been established, with a large capital, to prospect for petroleum in the Arak. It is expected to start operations soon. It is said that at Muzeireeb, at the end of the French railway, there is a petroleum well which was discovered through the smell of the oil in the spring there.—*Daily Consular Trade Reports*.

# Iron in Mill Pulp

By A. MCA. JOHNSTON

\*At one time ordinary cyanide practice in the mills of the Rand included concentrating to a rich product which was cyanided separately and which yielded, after many days' treatment, a fair proportion of its gold to the extractor boxes and incidentally added a considerable quantity of ferro and sulpho-cyanide to the solutions. The practice has of late years been superseded by treatment of this product with the sand and the presence of iron in cyanide solutions has thus not been so noticeable. Incidental, however, with the introduction of coarse screening and the beneficial effects of the tube-mill circuit (Dowling, 'Rand Metallurgical Practice,' pp. 123-129), a state has arisen, which, although present previously, has been emphasized by the existence of this circuit. A quantity of iron is present in the circuit, and remains there, it may be, for a very long period.

Iron is obtained in the crushed product from several sources. These may be tabulated as follows:

## Ore.

- (a) Metallic iron in the ore itself.

In a deep deep-level ore, iron has been found in the metallic state amounting to 0.013% of the ore.

## Mine.

- (b) Iron from wearing of the drills—either fine or in chip form.

- (c) Iron from broken drills.

- (d) Iron from bolts, nails, or pieces of scrap introduced underground. Hammer-heads are also a not unknown product in the ore sent to the mill.

## Mill.

- (e) Iron from wear of steel bins, chutes, and feeders.

- (f) Iron from wear of mortar-box liners.

- (g) Iron from wear of shoes and dies.

This has been stated to be about half a pound of iron per ton of ore crushed (Dowling, 'Rand Metallurgical Practice,' p. 132).

- (h) Iron from screens used in mill.

- (i) Iron from keys, etc., accidentally dropped in mortar-box.

## Tube-mill.

- (j) Iron from wear of feeders and of end liners.

- (k) Iron from iron or steel liners, rails, or pegs used in the tube-mill.

- (l) Iron from nails and scrap accidentally dropped into the circuit.

The iron from these various sources may be classed into two kinds, namely, that in a very fine state of division, due to its formation by abrasion, and that in coarser or pellet-like form, due to chipping, breakage, or accidental inclusion in the pulp. In mills where fine crushing is still in vogue, the percentage, per ton of pulp, of iron in a fine state will, naturally, exceed that found in mills where coarse crushing has been adopted, while again the removal of the larger pieces of iron from the mortar-boxes, along with the die sand, owing to their inability to escape therefrom in the pulp, will in the former case lower the amount of this class of metallic iron in the tube-mill circuit.

The specific gravity of the iron, when compared with that of the ore, renders it more liable to remain in the tube-mill circuit. It may continue there for some time, till at last, through some fortuitous circumstance, the finer portion is carried to the cyanide plant with the pulp, while the coarser particles continue their weary round till abrasion has rendered them in a fit state to follow. This iron in the tube-mill circuit affects the working in various ways. These may be summarized as follows:

- (a) The coarser particles are liable to scour the plates and cause loss of mercury. The mercury may later on be recovered from the launders, pumps, or traps, or it may be

lost by flouing and consequent escape into the cyanide plant.

- (b) In conjunction with the pyrite, the finest particles are likely to lie on the plates and so cover the amalgam that amalgamation will be interfered with and more frequent dressing of the plates necessitated.

- (c) Again, owing to the heavy nature of these particles, it may be advisable to supplement the flow of the water over the plates or increase the grade of fall in the plates so as to diminish the tendency to interfere with amalgamation.

- (d) The metallic iron is very apt to rob the plates of mercury by cohesion. This can be easily verified by visual inspection of the larger pieces, while microscopic examination of even the finest particles shows occasional specks of mercury.

- (e) Owing to its retention in the tube-mill circuit, the iron causes additional expense in tube-mill work, due to its weight and the necessary addition of water to increase the flow.

- (f) As a considerable quantity of this iron is in pellet form, its inclusion in the tube-mill product means less efficiency in the crushing process, for the pebbles, instead of crushing the sand, expend energy in flattening the iron. An examination of the product will show justification for this claim.

The fine iron which has overflowed into the cyanide pulp will, when the cyanide solution is pumped on the charge, be in one or other of the three states; metallic iron, ferrous oxide, or ferric oxide; the two latter being partly present in combination with water as hydrates. Iron in rusting forms an external covering of ferric oxide, with, underneath, a layer of ferrous oxide in contact with the metallic iron. Oxidation continues until the metallic iron has been converted into ferrous oxide and this eventually into ferric oxide. It is well known that ferric hydrate or ferric oxide does not form ferrocyanide with cyanide, and generally speaking, this covering over the iron protects it from the action of cyanide. The rubbing of the particles of sand on this, however, may break the protective coat so that the cyanide eventually reaches part, at least, of the ferrous oxide and metallic iron. Though the action of cyanide on iron vats or extractor boxes is so small as to be negligible from a practical standpoint, we must remember that the iron entering the plant with the pulp is in a fine state of division and therefore the more liable, not only to react with the cyanide, but to be changed into ferrous hydrate or ferrous sulphate, which are easily converted into ferrocyanide.

Thus the fine iron entering the cyanide plant may form, in contact with the cyanide solution, sodium ferrocyanide as follows:

The sodium ferrocyanide thus formed acts prejudicially on the solution of the gold, since it is a reducer and depletes the solution of oxygen (MacFarren, 'Cyanide Practice,' p. 43).

In addition to this effect of fine iron and its derivatives on cyanide, it is to be remembered that ferrous sulphide is produced when grinding pyrite between iron surfaces,  $\text{FeS}_2 + \text{Fe} = 2\text{FeS}$ , which latter is detrimental to gold-bearing cyanide solutions (Caldecott, 'Rand Metallurgical Practice,' p. 383). The same reaction would naturally take place in the tube-mill, when the sand and the metallic iron are being crushed by the pebbles.

These influences may appear of little importance in ordinary work and may be overlooked, but if it is remembered that in a solution entering the strong extractor boxes there has been used 326 lb. of sodium cyanide to hold in combination 0.02%  $\text{Na}_4\text{Fe}(\text{CN})_6$  in 1000 tons, the advantage of removing as much iron as possible from contact with cyanide solution, when it is in such a state that it will be attacked, is evident.

\*Excerpt from a paper submitted to the Chem. Met. & Min. Soc. of S. A., on August 17, 1912.

To eliminate this iron from the tube-mill circuit a magnetic separator was installed under the direction of A. C. Holtby, assistant mechanical engineer to the Consolidated Gold Fields. After running a few days a representative sample, or as near such as could be obtained, owing to the nature of the material, was taken, and the following tests conducted thereon. It was found that a considerable quantity of non-magnetic material had been caught, owing probably to mechanical adherence in the wet state to the magnetic portions.

*Microscopic Test.*—A microscopic examination showed the finer portion of the sample to contain its gold in minute nuggety form, mostly adhering to comparatively large pieces of quartz. A considerable amount of pyrite was present in the finest part, though this portion contained little, if any, amalgam or mercury.

#### ASSAY VALUE OF 14.50 DWT. PER TON

Grading Test	Per cent.	Cumulative, %	Assay V. dwt.
Aperture.			
- 0.276 .....	0.47	0.47	trace
+ 0.122 .....	7.10	7.57	27.4

+ 0.010 .....	26.03	81.71	20.0
+ 0.016 .....	13.76	95.47	44.4
- 0.006 .....	4.53	100.00	136.0
	100.00	Calculated 29.12	

This grading test shows that the + 0.010-in. aperture, amounting to 81.71% in weight, contains 41.1% of the gold, and the -0.006-in. aperture material, 4.53% by weight, contains 21.1% of the gold.

*Magnetic Test.*—A portion of the sample was separated by means of a magnet into magnetic and non-magnetic parts.

	Per cent.	Assay Value, dwt.	Total Gold in Sample, %.
Magnetic .....	73.5	1.6	8.3
Non-magnetic .....	26.5	48.8	91.7
	100.00	Calculated 14.1	100.0

It will be seen from this test that were it possible to entirely separate the magnetic from the non-magnetic, 91.7% of the gold would be retained in the latter.

*Cyaniding Tests,* both before and after roasting, gave very low extraction—from 2 to 4% of the gold. In these tests a very considerable amount of sodium ferrocyanide was formed. An analysis of another sample somewhat similar to the above showed:

	Per cent.
Iron (metallic) .....	87.4
Ferrous oxide .....	3.7
Ferric oxide .....	1.2
Pyrite .....	2.5
Silica .....	4.8
Moisture (at 100°C.) .....	0.2
	99.8

After the magnetic separator had been working about three months, a large sample, amounting to about a ton in weight, was taken for experimental purposes. This was piled in a heap on a flat clean surface where it was exposed to the action of the atmosphere. The weather was dry and cold during the three months of the test. The pile was turned over daily, while each alternate day it was thoroughly wetted, and once a week the water added contained 10 lb. of commercial salt. During the earlier part of the treatment considerable heat was evolved, due to the oxidation of the iron and the pyrite. Some temperature readings about 6 to 10 in. below the surface indicated from 160 to 170°F. At the end of four weeks a sample was taken from the lot and analyzed after being quickly dried on a hot plate.

Moisture (at 100°C.) .....	1.29

98.28

From this it will be seen that the bulk of the iron present as metallic iron has been converted into iron oxide. A portion of the sample was amalgamated by being shaken in a bottle with mercury for 12 hours.

	Dwt. per ton.
Assay value of original .....	6.1
Assay value of residue .....	3.8
Extraction by amalgamation .....	2.3
	= 37.7%

The treatment of continued exposure to the atmosphere and with occasional wetting with water plus one spraying with a solution of 0.01% sulphuric acid, was continued for four more weeks. The analysis and amalgamation tests on this are given in B. After a further four-weeks treatment with spraying and turning over, the pile was again sampled and analyzed. The results are given in C.

Grading.	B, %.	C, %.
+ 0.006 in. ....	2.70	0.94
- 0.006 in. ....	97.30	99.06
	100.00	100.00
Analysis.		
Silica .....	11.13	10.51
Alumina .....	trace	trace
Line .....	trace	trace
Magnesia .....	trace	trace
Iron (metallic) .....	3.04	1.04
Ferrous oxide .....	8.06	8.11
Ferric oxide .....	71.82	75.23
Pyrite .....	3.00	3.30
Moisture (at 100°C.) .....	1.60	1.00
	98.65	99.19

The larger percentage of + 0.006-in. pieces of metallic iron in B is due to the inclusion of one or two large particles. It is to be noted that all the sulphur has been calculated as pyrite. Portions would of course be present as sulphate and also as ferrous sulphide. The main object of the analysis was to obtain a general idea of the degree of oxidation of the iron.

C. A portion of this sample—that is, after 12-weeks exposure—was taken and amalgamated in a bottle for 12 hours with occasional shaking.

	Dwt. per ton.
Assay value of original .....	6.1
Assay value of residue .....	3.9
Extraction by amalgamation .....	= 36.0%

The residue from amalgamation was then cyanided (without previous drying) in a large bottle with occasional agitation. Time of treatment 36 hours, plus 24 hours for water washing.

	Dwt. per ton.
Assay value of washed residue .....	1.7
Extraction by cyaniding .....	2.2
Total extraction by amalgamation and cyaniding .....	4.4
	= 72.1%

The cyanide solution, 3 parts of solution to 1 of ore by weight, showed:

Originally,	0.165% KCN,
	0.065% NaOH.
After 36 hours treatment,	0.093% KCN,
	0.014% $K_2Fe(CN)_6$ ,
	0.009% KCNS.

The general conclusion to be drawn is that it is advantageous from a working, amalgamating, and cyaniding point of view to remove the metallic iron from the tailing. It can easily be oxidized by wetting and exposure to the atmosphere, but care should be taken that it be turned over and disintegrated daily, or at least each alternate day, so as to avoid the formation of lumps, until the greater part of it has been converted into the oxide. Generally speaking, this means until there is practically no more heat generated. Without this, the mass will form into hard cakes or pieces difficult to break up and slow to oxidize. Even with daily handling, little nodules form, the interior of which may consist of metallic iron and

ADDITION TO NIKKO ELECTROLYTIC REFINERY.

ferrous oxide, and may remain thus for some considerable time. The presence of silica, of course, helps materially in rendering the mass more porous and hence the more easily oxidized. When large pieces of iron in the form of bolts, nuts, or nails are present, the process would necessarily require a more lengthened period than is shown above.

It will be noticed that salt was used to assist in the oxidation process. It is a moot point whether this is necessary with this class of material. Personally, I should expect almost as quick results without its use. It is to be noted in conclusion that during the initial stages of the running of this separator, nearly a ton of magnetic iron, with silica and pyrite mechanically removed, was taken from the circuit daily. This has gradually decreased until after over six months running the daily yield of magnetic iron from a mill crushing 2500 tons per day is about 400 to 600 lb., or one pound per 5 tons of ore.

**Summary.**—The main points to be noted may be summarized thus:

(a) Iron is chiefly obtained in the tailing from the crushing plant, and is mostly present as small pieces, smaller than a pea, or as fine powder.

(b) Iron in this stage interferes with amalgamation and with the re-crushing in the tube-mills, and also consumes cyanide in the leaching vats.

(c) When removed from the pulp, this product can be easily oxidized by exposure to the atmosphere, wetting, and turning over.

(d) Failing any better means of disposal, this oxidized product will, if fed into the circuit, yield an average percentage of its gold to amalgamation and cyanidation.

## Electrolytic Copper Refining at the Nikko Copper Works

By TETSUTARO HASEGAWA

The electrolytic refinery at Nikko was built in 1905 to refine the copper from the Ashio mine of the Furukawa Mining Co., and absorbed the older Honjyo plant at Tokyo. It is owned by the Furukawa company and serves to refine the blister copper produced at the various mines of that company. The growing demand in Japan for copper wire and other merchant forms of the refined metal has afforded a steady market, and the trade-mark of this plant is now well known throughout the Orient. The first plant was built upon the series system, and a brief description of it appeared in the *Mining and Scientific Press* of October 14, 1911.

To meet the demand for increased output, an addition to the refinery has recently been constructed, of reinforced

INTERIOR OF ELECTROLYTIC REFINERY.

concrete, after the Kalm system. This is shown in the accompanying illustrations, and contains 108 vats in 12 groups of 9 vats each. In this case the arrangement patented by Walker is used. The vats are made of wood and lined with 8-lb. sheet lead. A group of 9 vats is 9 ft. by 30 ft., and 4 ft. deep. The anodes used are 2 ft. 3 in. wide, 3 ft. long, and  $1\frac{3}{4}$  in. thick, while the cathode strips are 2 ft. 4 in. wide, 3 ft. long, and  $\frac{1}{32}$  in. thick. A single vat will hold 18 anodes and 19 cathodes, spaced 4 in. centres.

At present the anodes are left in the vats about 21 days and the cathodes 7 days. The current density used is 20 amperes per square foot. The solution enters at the top of the vat and escapes at the bottom, the rate of flow being 100 cu. ft. per hour. The best results are obtained where the electrolyte is warmed to 40 or 50°C. The general arrangement of the plant can be seen in the illustration. The racks for the anodes are in the immediate foreground, just behind them are the tanks in which the anodes are washed, and to the rear of these are the racks for the cathodes. Behind these are the electrolyte vats, with the crane, of Whiting make, above them. The reservoir for electrolyte is seen to the right, in the prolongation of the line of the crane into the lower portion of the building, and the regenerators are seen in front. The annual output is expected to be 9,000,000 lb. of refined copper. The power-house is the small brick building, 54 by 36 ft., seen to the right in the illustration. Here a 450-hp. motor-generator set furnishes the current of 5000 amperes at 60 volts which is transmitted to the refinery.

PIG IRON imported into France during the first half of this year reached 1,291,777 tons, against 976,627 and 536,896 tons, respectively, in the same periods in 1911 and 1910.

OUTPUT of coal in New South Wales last year was 8,691,604 tons, compared with 9,147,025 tons for 1908.

# History of the Granite Mountain Mines

By C. P. BOWIE

The properties of the Granite Bi-Metallic Consolidated Mining Co. are situated in the Flint Creek mining district in Granite county, Montana, about four miles east of the town of Philipsburg. The collar of the Granite, or Ruby, shaft is within a few hundred feet of the top of Granite mountain, a prominent peak in a range which rises to a height of 8000 ft. above sea-level. No more inspiring view can be imagined than that from the dump of this shaft. One stands at an elevation of more than 3000 ft. immediately above the beautiful Flint Creek valley; in the summer-time a carpet of waving grain, in the winter snugly tucked beneath a blanket of snow. On the east is a rugged range of mighty mountains stretching hundreds of miles to the south, studded with lofty snow-capped peaks standing in bold relief against the sky.

The story goes that late in the fall of 1872 a man named Holland was hunting in the vicinity of this peak. He

PART OF MONTANA.

was pursuing a wounded moose which crossed a ledge of rock, where the Granite shaft stands today, and dislodged a loose fragment. The rock rolled down the mountain-side and broke against a boulder in the path of the hunter. Being by nature a prospector, Mr. Holland stopped to examine the rock, and upon discovering that it contained quartz, promptly forgot his quarry and turned his attention to the ledge from which the fragment came. He found that there was a short outcrop, about two feet wide, of barren-looking quartz between walls of compact granite. Later that year he located a claim on the outcrop and sank a shaft about 15 ft. deep, but the assay returns were so discouraging that the location was allowed to lapse, and it was not until two years later, in company with three others, that he re-located and definitely commenced development.

At this time C. D. McClure was president of the Hope Mining Co., which was operating extensively about one mile north of Philipsburg. After much persuasion on the part of the locators, he was induced to take a bond on the prospect for \$40,000. Mr. McClure spent a considerable sum in development, and finally decided to see if he could not interest outside capital. Accordingly, he prepared to make an extended trip East. He left in charge of the mine a man by the name of Hogan, with instructions to continue the work as long as silver "remained up." This Irishman, although perhaps not overburdened with 'book learning,' had ideas of his own, and soon after

Mr. McClure's departure devised the system of giving each miner, as he entered the shaft, three candles and five sticks of powder. A day's work was supposed to have been completed when the candles were consumed and the powder placed in a hole of the proper depth and made ready for shooting. But the wall rock was very hard and the vein none too soft, so that it soon became the rule that about three of the sticks of powder went into a convenient cache behind the lagging in one of the drifts.

Butte at this time had risen to the dignity of a daily paper. One morning this paper came into the hands of Hogan, and to his consternation recorded silver as \$1.14 $\frac{1}{4}$  per ounce. The issue of the week previous had said \$1.14 $\frac{1}{2}$  per ounce. Not being versed in the art of fractions, it became a serious question whether it was going up or down. Nothing abashed, Hogan went to the carpenter's chest and secured a brace, a  $\frac{1}{2}$ -in. bit and a  $\frac{5}{8}$ -in. bit. Then he went out to the stull pile and sat down. He bored a hole with the  $\frac{5}{8}$ -in. bit and found that the  $\frac{1}{2}$ -in. bit would enter with room to spare. The day was saved; it was still going up. He replaced the tools in the carpenter's kit and went underground, pondering on what might have been the consequences if the half-inch bit had been too large. That same day some wag of a miner set his blast in the cache behind the lagging. When the shots were fired, at the close of the shift, there was a terrific explosion which almost wrecked this portion of the mine, but which broke through a 'horse' of granite and exposed a ribbon of high-grade ore. By the time Mr. McClure returned from the East the wreckage had been cleared away, and the damage done was reported to him as having been caused by a 'slide.' The ribbon of ore was followed and, in 1883, 1435 tons of ore broken from it was worked through a local custom mill and netted the company \$273,898.

The future of the mine from this time on was assured. The construction of a 20-stamp, dry-crushing mill, just below the collar of the shaft, was begun at once, but was later increased to 80 stamps. On grading for the retort-house, the top of another ore-shoot was found which proved to be the richest and most extensive in the mine. For a considerable period no attempt was made to work anything but the high-grade ores. On the 600-ft. level an 11-ft. face of ore carrying 150 oz. of silver per ton was left untouched for a number of months, the mill being busy on richer material.

In 1882 the Bi-Metallic Mining Co., composed of men who had been instrumental in the purchase and development of the Granite company, was organized. A 3-compartment shaft was commenced about 1000 ft. from the west workings of the Granite, and was sunk to a depth of 200 ft. before cross-cutting. The vein was there; driving soon disclosed ore. The mine proved later to have a large part of the same vein which was exploited through the Granite workings, although the ore was hardly so rich. A 100-stamp chlorination mill was built at a place known as Bi-Metallic, on Douglas creek,  $1\frac{1}{2}$  miles south of Philipsburg, and was connected to the mine by a wire-rope tramway four miles in length.

The ten years from 1883 to 1893 were very prosperous for both companies. During this period the Granite mine produced \$20,000,000 in silver, of which more than \$11,000,000 was paid in dividends, notwithstanding the fact that the company constructed, at great expense, a second mill of 100 stamps at Rumsey, in Fred Burr canyon,  $1\frac{1}{2}$  miles southeast of the mine. This mill was connected to the mine by a wire-rope tramway, and a branch of the Northern Pacific railroad was extended to it for a distance of 7.7 miles from Philipsburg. The production of the Bi-Metallic mine for this decade was about

\$6,000,000, and \$2,000,000 was paid in dividends. When the crash came in 1893 both mines were closed.

The towns of Philipsburg and Granite naturally enjoyed their full measure of prosperity during these years. The town of Granite, which today is practically deserted, boasted some 3000 inhabitants and was in many ways unique. It was built around the two mines. The streets were mostly roads graded into the mountain, the upper side often was 50 ft. higher than the lower, and, as the tenderfoot from St. Louis wrote home, "the longest of them extended only a block or two and ran up a tree." There was Magnolia avenue, close to the mines and mill, on which were the homes of the chief officials; Sunnyside, the abode of the next in rank; Finn Town, Bell avenue, and Denigol where the masses lived, and Whiskey Hill, the business centre. On Whiskey Hill every door was a saloon in which gambling devices innumerable could be found. Business was good everywhere. Contractors, merchants, and tradesmen grew rich as if by magic; fortunes, too, were won and lost at the roulette wheel, the faro bank, and monte game; and each night the lights of the underworld blazed unabashed.

per year. Subsequently they have been partly reopened from time to time above the drainage adit and worked under leases. At the present time a cyanide plant is being constructed in the Bi-Metallic mill to work over the mill tailing, of which there is some 300,000 tons impounded in Douglas gulch. The production of these two mines laid the foundations of many large fortunes of the Middle West. It aggregated over \$32,000,000, and nearly \$15,000,000 was paid in dividends. Of this amount, the Granite mine produced approximately three-quarters, and its dividends were about \$13,000,000.

The strike of the vein was almost due east and west, and the dip from 8°N. to 8°S. It varied in width from 2 to 150 ft., but the pay-streak was usually confined to a ribbon of ore not over 22 ft. at the widest. The walls were almost everywhere well defined, the vein being separated from both by a clay gouge. The highest-grade ores were sulphides and were found at a depth of never less than 200 ft. from the surface. The country rock is a medium-grained granite, composed chiefly of quartz, feldspar, mica, and hornblende, and cut at many places by small dikes of aplite. As a rule, the walls in the vicinity

BI-METALLIC MINE AND TOWN OF GRANITE.

DUMP OF THE GRANITE MINE.

The mines remained closed until 1898, when the two companies were consolidated under the name of the Granite Bi-Metallic Consolidated Mining Co., capitalized at 1,000,000 shares. Because the ore reserves in the Bi-Metallic mine were larger than those in the Granite mine, 200,000 shares of the Bi-Metallic company were transferred for 600,000 shares of the new company; 400,000 shares of the Granite stock being traded share for share. Extensive improvements were at once begun. A drainage adit 8850 ft. long was driven from the canyon of Douglas creek, meeting the Bi-Metallic shaft at a depth of 1000 ft. and the Granite shaft at 1450 ft., thereby greatly reducing the pumping cost. A subsidiary company called the Montana Water, Electric Power & Mining Co., was organized, and under its supervision a reservoir several square miles in extent was constructed on Georgetown flats, about twelve miles south of Philipsburg, and a hydro-electric plant was constructed in Flint creek canyon immediately to the north of the reservoir, which supplied the mine and mill with 1100 hp. The mills at the Granite mine and at Rumsey were completely abandoned. As far as possible the machinery from them was used in constructing the Bi-Metallic mill to treat tailing and high-grade ore. For low-grade ore a 300-ton concentrator was built at Granite, immediately below the collar of the Bi-Metallic shaft. The concentrate from this plant was sent to the Bi-Metallic mill by tramway and thence by rail to a smelter at Helena.

With these arrangements the mines were operated spasmodically until August 1905, when, because of the low price of silver and decreasing grade of the ore, they were closed. During this period they produced about \$1,000,000

of the vein are very hard, but in some places the ferromagnesian minerals have locally been altered to green silicates. Large angular blocks broken from the walls form horses in the vein in many places, and, almost without exception, have been found to be completely barren. The Granite (or Ruby) shaft is 1500 ft. deep, and the Bi-Metallic (or Blaine) shaft 1800 ft. deep. The vein has been followed and stoped 2600 ft. below the surface, and there are altogether more than 20 miles of drifts and cross-cuts.

As is indicated by the large percentage of gross output which was paid in dividends, the management of both mines was efficient from the outset. Specialists of broad training were employed in every department. Some of the foremost men in the profession today were at one time or another connected with the work of one or both of these mines. There is, however, one criticism to be made of the management of the properties, one which, unfortunately, applies to the management of many great mines which have passed into history. Too much money was paid in dividends and too little held in reserve for prospecting new orebodies and providing means for profitably handling low-grade ores. The great wealth which the mines produced has been turned into other channels. While there are undoubtedly extensive bodies of low-grade ore still remaining in these mines, and perhaps some of high grade, yet without an initial expenditure of large sums of money, which the stockholders are loth to advance, they cannot be mined and worked at a profit. In the business of mining, or in any other business, it is a short-sighted policy which plans only for today and takes no thought of tomorrow.

## Fire Assay Charges

By D. C. LIVINGSTON

In the fire assay for gold and silver in ores and metallurgical products, the ores fall into three divisions, of which the first two are most common. These are (1) silicious ores; (2) sulphide ores, with galena and pyrite; and (3) basic ores with hematite and limestone, having a neutral, reducing, and oxidizing action, respectively.

Many books and articles have been published on assaying, and charges given for almost any ore; but when an ore is brought in for assay it is sometimes difficult to tell its composition, especially if ground fine. The object of this article is to give a few fluxes by which practically any ore or metallurgical product can be assayed, and good results obtained.

There are three methods which are generally used in fire assaying for gold and silver in ore: (1) the crucible assay, in which an excess of litharge is used over that required to give lead for the button, and in which either an oxidizer or reducer is added according to the character of the ore; (2) the crucible assay in which only sufficient litharge is used to give the required size of lead button, iron nails being added to the charge in the case of sulphide ores; and (3) the scorification assay. The main difference between the first two methods is that with the first the litharge acts principally as a flux, and in the second it acts as the carrier of lead for the button. Also, in the first method, the atmosphere in the crucible, during fusion, is mainly oxidizing; and in the second it is reducing. Each of these methods has its particular use.

For ores of the first division the first method is the usual one. Experiments show that the best results are obtained where a slag is used which is a mono-silicate of  $\text{PbO}$  and  $\text{Na}_2\text{O}$ . For a pure silicious ore, the following charge will give this slag, which is calculated to contain enough  $\text{PbO}$  to give a lead button of 25 gm., as well as enough to combine with the silica in the proportion of a mono-silicate:

Ore .....	$\frac{1}{2}$ A. T.
Litharge .....	82 gm.
Sodium bicarbonate .....	39 "
Reducing agent for 25-gm. button.	

This charge is somewhat large on account of the amount of soda, and equally good results can be obtained from the following charge, which has the advantage that a 15-gm. crucible can be used for  $\frac{1}{2}$  A. T. instead of a 20-gm. crucible, which is necessary for the above:

Ore .....	$\frac{1}{2}$ A. T.
Litharge .....	75.0 gm.
Sodium bicarbonate .....	12.5 "
Potassium bicarbonate .....	12.5 "
Flour .....	2.0 "
Borax glass and soda cover.	

In practice it saves time to prepare the fluxes beforehand. This flux contains the following percentages by weight:

	Per cent.
Litharge .....	73.5
Sodium bicarbonate .....	12.25
Potassium bicarbonate .....	12.25
Flour .....	2.0
	100.00

The fusion should be conducted quickly, at a fairly high temperature, the muffle being hot when the charges are placed in it. A quick hot fusion is one of the main essentials in excess litharge charges, and the time ought not to exceed 30 minutes.

For sulphide ores any one of the three methods can be used, depending upon the character of the ore and whether the assay is for a hand sample or control. By No. 1 method practically any ore, and the majority of metallurgical

products, can be assayed. It is especially suitable for ores high in copper, arsenic, and antimony, because, owing to its oxidizing nature, the greater part of these elements is oxidized and slagged. The principal objection to the method is that with sulphide ores a preliminary assay is necessary in order to determine the right amount of the oxidizer to add, which is usually nitre. Another objection to the method is that the flux is more expensive than that used in the iron-nail assay. No. 2 method is unsuitable for the above classes of ore owing to the reducing condition in the crucible, these constituents will be reduced to the metallic state, and will be brought down with the lead into the button. It is of course possible to scorify this button, but the results will invariably be low, particularly in silver, as well as requiring more time for the extra operation. For sulphide ores consisting principally of pyrite and galena, the iron-nail method will give good results, and has the advantage of saving a preliminary assay.

The scorification assay can be used on almost any ore, but should, in most cases, be considered as the last resort for ores that cannot be assayed by any other means. This is true, particularly, in the case of gold ores, on account of the small sample that can be taken for assay. A greater length of time is also required for the operation than for the excess-litharge assay.

In using method No. 1 for sulphide ores, a less silicious slag is generally employed than for quartz ores, and more litharge is used. One of the best charges for nearly all kinds of sulphide ores and mattes is the following:

Ore: For pyrite or galena ores, or where not very large quantities of Cu, As, Sb, etc., are present .....	$\frac{1}{2}$ A. T.
Ore: For ores containing over 3 or 4% copper, or much As, Sb, etc.; or where the ore has such a high reducing power that more than 20 gm. of nitre will be needed for $\frac{1}{2}$ A. T. (It may be necessary to reduce this amount still more with ores running over 35% copper.) .....	$\frac{1}{4}$ A. T.
Litharge .....	100 gm.
Sodium bicarbonate .....	7 "
Potassium bicarbonate .....	7 "
Silica .....	4 "
Borax glass .....	5 "
Nitre to suit, and borax-glass cover.	

The percentage of the reagents in the flux will be as follows:

	Per cent.
Litharge .....	81.3
Sodium bicarbonate .....	5.7
Potassium bicarbonate .....	5.7
Silica .....	3.2
Borax glass .....	4.1
	100.0

The charge for  $\frac{1}{2}$  A. T. will be 123 gm., but this amount can be reduced somewhat for  $\frac{1}{4}$  A. T. For high-grade galena ores, it is better to reduce the litharge, as the lead button is liable to be brittle, due to the presence of litharge. The fusion should be done quickly, the charges being placed in a muffle already at cherry-red heat, and finished at a somewhat higher temperature than that necessary for silicious ores. There is little danger of the crucibles boiling over even with as much as 18 gm. of nitre, in a 20-gm. crucible. Providing the fusion is properly carried out at a sufficiently high temperature, practically any sulphide ore can be assayed with this charge by varying the amount of ore taken according to its character and impurities contained. With the above charge the oxidizing power of nitre can usually be taken at between 4.2 and 4.5. It is essential that the same flux be used in the preliminary assay, and if possible the same amount of ore as that required for the final assay, as the condition will then be similar, and there is very little time saved by taking  $\frac{1}{10}$  A. T., as is often

recommended. If the preliminary assay shows that some reducing agent is necessary in order to obtain a 25-gm. button, flux No. 1 can be added in the right proportion, or approximately about 4 gm. of flux for 1 gm. of lead required, and flux No. 2 can be reduced accordingly. As a general rule, it is safer to have too large than too small a button.

On sulphide ores there are numerous charges given for the iron-nail method, the following being a good one:

Ore .....	1/2 A. T.
Litharge (according to amount of lead in the ore) .....	18 to 30 gm.
Sodium bicarbonate .....	15 "
Potassium carbonate .....	15 "
Borax glass .....	10 "
Silica .....	4 "
Flour .....	3 "

Nails, 2 to 6, and a cover of soda and borax glass, or salt.

The flour is not necessary in a heavy pyrite ore, but does no harm, and if the flux is prepared ahead, it should be added, because it will be needed with ores deficient in sulphur. In the fusion with this charge it is best to have the temperature of the muffle low at the start, raised gradually, and finished at a high temperature, in order to insure perfect fusion and a good pour. Providing only pyrite or galena ores, or ores with only small quantities of copper, etc., are to be assayed, this method is quite reliable, but it is useless to expect good results on ores containing large amounts of such interfering elements, for the reasons already given.

In the scorification assay of sulphide ores, the usual charge in a 3 1/2-in. scorifier would be as follows: ore, 1/10 assay ton; test lead, 50 to 80 gm., the latter used with a high percentage of copper, or arsenical ores; cover of silica and borax glass. The method of conducting the assay has often been described. It is a good reliable method, especially for high-grade silver ores, but is not generally as satisfactory as the crucible, for the reasons previously given.

For basic ores—hematite, limestone, etc.—the following charge will give satisfactory results, as a rule:

Ore .....	1/2 A. T.
Litharge .....	.60 gm.
Sodium bicarbonate .....	.15 "
Borax .....	.10 "
Silica .....	.5 "

and flour according to the oxidizing power of the ore, which depends upon the amount of ferric iron that it contains. The percentages of the reagents in this flux are as follows:

	%
Litharge .....	66.7
Sodium bicarbonate .....	16.7
Borax glass .....	11.1
Silica .....	5.5
	100.00

There are very few ores which could not be assayed by either flux No. 1, 2, or 3 without any change excepting the amount of ore taken. I have tried flux No. 2 on numerous checked smelter samples of sulphide ores and mattes, with good results. Where there was any variation it was almost always the assay with flux No. 2, which was the higher, and this was particularly the case where the smelter assay had been made by scorification.

L. VOGELSTEIN & Co. gives the following figures of German consumption of foreign copper for the months January to August 1912.

	Tons.
Imports of copper .....	142,464
Exports of copper .....	6,057
Consumption .....	136,407

as compared with consumption during the same period in 1911 of 119,943 tons. Of this quantity 124,642 tons was imported from the United States.

## Rock-Crushers at Kalgoorlie

By M. W. VON BERNEWITZ

The relative merits of jaw and gyratory types of crushers have often been discussed in technical papers, so I shall only refer to the general practice of crushing ore, and the cost of this work at the large mines of Western Australia.

At one time it was customary to have crushers on top of the mill storage-bins; but now the practice is to have the crusher-house entirely separate from the mill. The broken ore is conveyed from the crusher to the mill-bins by an 18 or 20-in. belt-conveyor of either rubber or balata construction. Perched on the top of a mill, a crusher is a nuisance, as it shakes the whole building, repairs are difficult, and the distribution of ore is not easy. Crushers with the Bigelow patent toggle, in which

BIGELOW SHEARING TOGGLE.

10 steel rivets, with a total shearing strain of 360 tons, are sheared off in case of an unbreakable substance getting between the jaws, are extensively used. This shearing is somewhat like the break-pin arrangement in the Gates breaker. Adjustment of the No. 7 1/2 Gates, type K, is made at the top instead of at the step. The crushing head and spindle are suspended from this point, relieving the bottom of much weight. The spiders are set parallel to the flow of ore from the grizzlies, the ore thus fills the gyratory breaker all round the crushing head, tending to high capacity and efficiency. Motor-driven crushers are generally satisfactory, and circuit-breakers or fuses rarely blow out, although the feed is so irregular. The No. 5 and 7 1/2 Gates take 30 and 65 hp., respectively, when full of ore; and the 30 by 12-in. jaw crushers take 30 hp. each.

Stage crushing is considered preferable at the large mines, including the Boulder, Horse-Shoe, Ivanhoe, and Perseverance. It is rather too much to expect any single breaker to crush 700 tons per day, considering the sizes in use and the number of hours at work. Some mines crush ore during the whole 24 hours; others during two shifts; and others again during day shift only. There was at one time an idea that motors would not do for driving crushers, as the sudden rush of ore into an empty machine caused a high flow of current which would open the circuit-breaker or other safeguard; but in practice this proves not to give trouble. The crushers at the Associated Northern, Ivanhoe, and Kalgurli are driven by steam-engines. The former is driven from a counter-shaft, by belt from a clutch pulley on the main mill shafting. The Ivanhoe drives a countershaft by a small engine, the counter carrying rope pulley from which three ropes drive

a No. 7½ crusher, and two ropes each drive the two No. 5 Gates below—rather an unusual arrangement. The Associated, Boulder, Hainault, Horse-Shoe, Ivanhoe, Kalgurli, Lake View, and South Kalgurli crushers are fed directly from skips, the ore of course first passing over grizzlies. The Associated Northern, one section of the Boulder plant, and Oroya Links crushers are fed from cars, while the Perseverance and one section of the Oroya Links are fed from a bin into which the skips are dumped.

I have seen the break-pin arrangement work properly on the No. 5 Gates, but the larger size is not provided with it. The Horse-Shoe had one crusher broken by an iron bar, while the Associated had two spiders broken, one hopelessly and the other cracked. A 2-in. band was shrunk around the cracked spider, while ½-in. boiler plate was studded on the arms, with good results. Recently a spalling hammer got jammed between the head and concaves, but the circuit-breaker, which is set at 135 amperes, flew out, and no damage was done. The table following gives details of the breakers at work at Kalgoorlie:

DETAILS OF CRUSHING PLANTS AT KALGOORLIE.

Name.	Jaw.	Gyratory.	Type.	Size.	*Tons crushed per day.	How driven.	Cost per ton, cents.

\*Deduct 20% for fine.

†The Boulder also has 3 H-type Gates breakers for crushing ore to about 1-in. size for the Griffin mills.

In these costs the transport of broken ore to mill-bins is included; this item is about 4c. per ton.

It will be seen that there are 12 jaw and 16 gyratory crushers at work at the mines mentioned, and, so far as can be gathered, each type is giving satisfaction. When once supplied with new wearing parts, each machine works for a considerable time without any repairs. The life of jaws, mantles, and concaves varies considerably with the class of ore broken and the composition of the steel. Jaws last up to 180 days; while the No. 5 Gates liners will crush 100,000 tons. The No. 7½ Gates liners will run fully 270 days. Of the ore raised from the mines, about 20% is fine enough to pass the grizzlies. The hardest sulphide ore contains 65 to 75% silica. Manganese steel liners are quite satisfactory; but not cast iron, chilled for about ½-in. depth, as I saw one set replaced not long ago.

It is not necessary to fill in behind the jaws with metal, the bolts being sufficient to hold them in place; but of course a new mantle or set of concaves is run with zinc, as usual. Concaves are now supplied in two pieces, so that the bottom half, on which the bulk of the crushing falls, may be thrown out and another fitted in. In doing this, it is necessary to remove the top sections, to make the job easier. The wheel eccentric is generally changed at this time, although if poor metal is used for it, it will not last many weeks. One lasted 18 months in a No. 5 Gates and 9 months in a No. 7½. Plenty of good oil is essential for the gyratory, at the spider, where the spindle is suspended, as well as for the eccentric and bearings, and grease for the gear. The oil for the eccentric should be renewed every week, using some 5 gal. The bearings of the jaw crusher are lubri-

cated with any good grease, squeezed in by the Stauffer system. The Perseverance casts the spiders and steel heads for the No. 3 Gates with good results.

Transport of ore from crushers to mills is closely connected with crushing; in fact, costs generally embrace breaking and storage. At the Associated the crusher feeds on to the 18-in. inclined belt by a peculiarly-shaped chute, really a compound bend, whence it is elevated to a horizontal belt, which discharges the ore into either of two storage-bins holding 500 tons each. The Associated Northern distributing belt discharges into three separate bins. The crusher here stands on top of the mill-bins. The ore from the Edwards' crushing plant of the Boulder is taken by a 20-in. belt-conveyor to the mill, meeting the ore from the main shaft crusher, when part goes to the ball-mill bin and part to a trommel, the coarse from this being crushed in three H Gates crushers, set at about 1-in. opening; then all the fine ore from the trommel and the small breakers goes by belt to the Griffin mill-bin. The Horse-Shoe has two crushing stations, and from

the storage-bins the ore is conveyed by rubber belts to the stamp-mill. The Ivanhoe conveyor is fed by Challenge feeders, and by an automatic tripper the ore is discharged into the stamp-mill bins. From the Kalgurli storage bin at the main shaft the ore is carried in ½-ton skips by a Bleichert tramway to the ball-mill bins. The Lake View broken ore is conveyed to the stamp-mill by long inclined belts; that from the Star mine being transported in cars drawn by a small locomotive to the Lake View, where it is dumped down a chute, hoisted, and conveyed to the stamp-mill. The jaw-crusher at the Perseverance is fed from a bin at the mouth of the main shaft, which is filled by the skips in the shaft and cars from No. 6 shaft, worked by a ropeway. The crusher discharges upon a belt which feeds two No. 3 Gates, the ore dropping in a 1000-ton capacity bin, from which a belt elevates it to the ball-mill bins. The Oroya Links ore comes from the Oroya mine by Bleichert aerial tram, and from the Eclipse mine in cars, holding three tons each, drawn by horses. All the broken ore is dumped into the stamp-mill bins by a tripper.

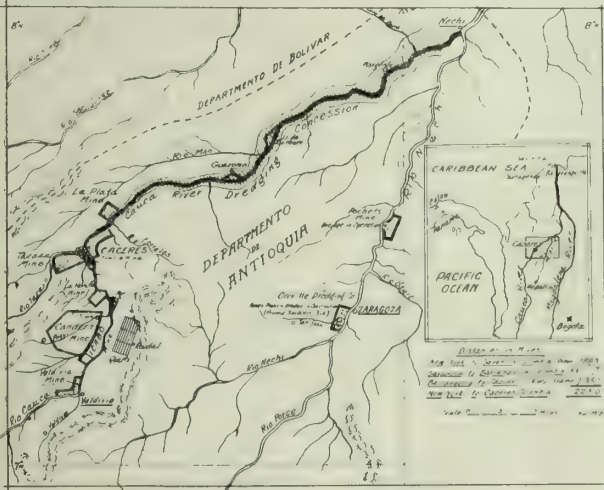

On the whole, the crushing plants on the 'Golden Mile' are worked cheaply, and give a minimum of trouble. Crushers get rough work to do, and they need constant attention, not necessarily repairs. The engineer's staff should examine them thoroughly the first thing every morning.

THE quantity of nickel exported from New Caledonia during June was 4873 tons, making the total exports of that metal from the first of the year 23,842 tons. The exports of chromite for June amounted to 1721 tons, the total exported since January 1 being 25,991 tons.

Dredging in Colombia

Holders of Oroville Dredging shares will be particularly interested in a report by Silas H. Wright, American consular agent in Colombia, South America. The report in part is as follows: The mining industry of the Department of Antioquia continues to attract outside capital, and particularly American capital, although the actual gold production for the past year or more has been less than for previous years, due to various causes. Antioquia until recently produced on an average some \$4,000,000 annually, but now it is not more than \$3,000,000; even this is a considerable amount under the circumstances. The fact is that small operations such as the native miner carried on so long at a profit are being rapidly exhausted, and today more capital is required to operate and equip mines than previously. This capital must come from the outside—as it is coming now almost daily—because it is not to be had in this country, and because the mines here contain the gold in profitable amount. This industry will naturally become a leading, if not the chief, industry of

DREDGING FIELDS OF COLOMBIA.

Antioquia, but foreign capital, energy, and modern appliances are necessary. Better transportation facilities have also reduced costs. American and English interests are now largely represented throughout the Department of Antioquia, both in mineral exploration and in the equipment and operation of mines. Englishmen usually appear to prefer quartz mining, while Americans mostly take to placer mining. This past year various undertakings by American companies on both the Cauca and the Nechi rivers in the extreme northern portion of the department, principally in drilling (with Keystone and other drills) for dredging operations, have met with marked success. The Oroville Dredging Co., of California, is about to place a modern dredge on the Nechi river near Zaragoza, and two other large American companies expect to place dredges on the Cauca river in the near future. This region is perhaps the richest and largest placer region in the department, especially suitable for such enterprises on a large scale, having both extensive area and high values. Being also on navigable rivers with cheap transportation, it bids fair to become the dredging ground for Colombia. On the Porce river also, in the upper portion of Antioquia, not far from the city of Medellin, several American enterprises are operating hydraulic elevators with good results. There are numerous similar enterprises under American management throughout the department, and from indications more are coming rapidly. While there are foundries in Medellin where certain classes of castings and machinery may be obtained, and where repairs may also be made up to a certain point, there are no representative American machinery houses

here for furnishing mining or any other class of machinery. Nearly all machinery for these mines, especially those operated by Americans, comes direct from the United States. The most important property under development is that of the Pato mines, financed through the Oroville Dredging Co., which has expended a large sum on its dredge, power-plant, and the largest cement dam in Colombia. It is expected that the plant will be ready to operate in October.

**Goldfield Consolidated Report**

During August the total production of the Goldfield Consolidated Mines Co., according to the report of J. F. Thorn, general superintendent, was 32,538 tons, containing \$465,289.07, or an average of \$14.30 per ton, of which 30,330 tons was milled with an average extraction of 89.31%, and 2208 tons of an average value of \$15.26 per ton was shipped; the net recovery from all ore being \$12.88 per ton. The total net realization was \$223,580.71, or \$6.87 per ton. During the month 4319 ft. of development work was performed. The total cost of mining, development, transportation, milling, office, and general expense was \$6.14 per ton, distributed as follows:

Mining (including stoping and development)	\$3.30
Transportation	0.11
Milling	1.86
Marketing	0.05
General expense	0.28
Bullion tax	0.03
Marketing ore shipped	0.53
Total cost of operation	\$6.16
Miscellaneous earnings	0.02
Net cost per ton	\$6.14

In the Combination mine 136BX, the new stope from the second level, 200 ft. northeast of the shaft, produced 577 tons of \$22.60 ore. The 217 drift on the 200-ft. level south in the Jumbo No. 2 cut a small vein which produced 50 tons of \$74 ore. Not enough work has been done to determine the extent of this orebody in length or depth. The stopes being carried through the old Sheets-Ish and Begole lease workings in the Mohawk produced 1801 tons of ore averaging \$19.25 per ton. The stope in the old Hayes-Monette lease workings above the 250-ft. level produced 454 tons of ore averaging \$24 per ton. The 202 stope being carried through the old Francis-Mohawk workings produced 531 tons of ore averaging \$20 per ton. The 348 stope being worked through the Loftus-Davis lease workings above the 450-ft. level produced 291 tons of \$71.60 ore. The 490-I stope, which was cut out of the 438X drift between the 600 and 450-ft. levels, produced 1856 tons of ore averaging \$84 per ton. In the Clermont the 571 drift on the downward extension of the 510 orebody, between the 900 and 750-ft. levels, produced 100 tons of ore averaging \$40 per ton. On the 1300-ft. level of the Grizzly Bear a sill is being cut in the 802 orebody and has produced 140 tons of average \$22 ore, which was shipped to the smelter. The Grizzly Bear shaft has been completed to the 1400-ft. level and a sump cut, and the drift on this level advanced 30 ft. from the shaft.

UPON the entry of goods and the payment of customs duties thereon in Colombia, the collector of the custom-house through which the goods are imported shall fix a period, not to exceed 15 days, within which the goods must be removed from the customs warehouse by the importer or his agent. In case the goods are not removed within the time set, the following storage charges will be collected: For each of the first 30 days, 2c. per package, not exceeding in weight 75 kg. (kg. = 2.2046 lb.); for each of the following 90 days, 5c. per package; and thereafter 10c. per day per package until a year from the date of the importation of the goods.

## New York Meeting of the Institute

The adjourned annual business meeting of the American Institute of Mining Engineers was held at the headquarters of the Institute, 29 West 39th street, New York, on Monday, October 7, at 10 a.m. The following members were in attendance: H. F. Bain, W. deL. Benedict, John Birkinbine, D. W. Brunton, J. A. Church, F. W. Cottrell, J. S. Cox, James Douglas, H. W. DuBois, E. L. DuFourcq, A. S. Dwight, Anton Eilers, J. R. Finlay, L. C. Graton, H. G. Granger, H. M. Howe, L. D. Huntton, Hennen Jennings, Sidney J. Jennings, E. R. Jones, J. N. Judson, Charles Kirehloff, A. R. Ledoux, Waldemar Lindgren, Charles McCrery, P. N. Moore, E. E. Oleott, E. W. Parker, E. G. Spilsbury, G. C. Stone, Bradley Stoughton, Joseph Struthers, and Kirby Thomas. About 1400 proxies had been received from members unable to be present, but these were not used. Differences of opinion existing in the membership were reconciled by previous conferences and the greatest harmony marked the proceedings. The resolutions passed by the meetings of members held at San Francisco and Los Angeles, as given in the *Mining and Scientific Press* of September 28, were read. The report of the Committee of Five was accepted, the committee thanked for its efforts, and discharged. All the pending amendments to the constitution of the Institute, as proposed in the circular of October 1911, were voted down. Amendments to the constitution and by-laws were proposed by C. R. Corning, providing for a class of Junior members; separate investment of the funds received from life memberships; stricter treatment of members in arrears for dues; secretaries of the Board of Directors and Council to be elected by the bodies served; yearly budgets to be prepared in advance and no expenditures to be made except as authorized by the directors, who shall hold monthly meetings for the consideration of the business of the Institute; change of name of the president and vice-president of the Council to chairman and vice-chairman, respectively; the creation of the office of secretary emeritus; increase of dues not more than \$5 per year, if necessary, until the land debt is extinguished, when they shall automatically revert to \$10 per year; nominations for officers of the Institute to be announced not later than November, thus permitting effective opposition; the appointment of a business manager for the Institute by the Board of Directors; the use of letter ballots; the development of local sections; creation of topical divisions; specification of the terms upon which affiliations with other societies may be entered upon; and many minor changes intended to clarify the business conduct of the Institute. A committee of the Directors and Council, of which J. W. Richards was chairman, in conference considered some of these changes unnecessary, but was in substantial agreement with the greater number. Messrs. Richards, Rand, and Kirehloff introduced an amendment providing that the secretary shall be elected by the Council, with the approval of the Board of Directors, and creating the office of secretary emeritus, as provided in the amendment by C. R. Corning. All these amendments were ordered printed and sent to the members for discussion at the meeting to be held at Cleveland, October 28, 29, 30, and 31. The business meeting was then adjourned to New York on November 12, when the wording of the amendments will be perfected so that final action can be taken at the annual business meeting in February 1913.

The 103rd meeting of the Institute, for the reading and discussion of professional papers, will be held in Cleveland, Ohio, beginning Monday evening, October 28, 1912. The Institute headquarters will be established at the recently completed Statler hotel, where a bureau of information in charge of C. B. Murray, secretary of the local committee, will be maintained. The early sessions will be held in one of the rooms of this hotel, and the concluding session in the Electricity building of the Case School of Applied Science. The arrangements for the

meeting, apart from the technical sessions, are in the hands of the local committee, D. T. Croxton, chairman, and C. B. Murray, secretary, Perry-Payne building, Cleveland, to whom all inquiries concerning local matters, except those referring to papers and discussions for the technical sessions, should be addressed. The control of the papers and discussion will be exercised by the president and secretary of the Council as usual. No special reduction of railroad fares for attendance at this meeting is practicable, and members will make their own arrangements in this respect.

Details of the technical sessions of the meeting, and visits to points of engineering and scenic interest, will be given in the program of the local committee. Members wishing to visit during the week any individual plant or work in Cleveland or vicinity will be assisted to do so by means of suitable introductions and guidance upon notice given by them in advance to C. B. Murray. The following provisional program has been arranged, subject to possible but not probable change by the local committee:

Monday, Oct. 28—Afternoon: Registration at headquarters, Statler hotel. 8:15 p.m.: Informal social meeting at headquarters.

Tuesday, Oct. 29—At Statler hotel: 10 a.m., technical session; 2 p.m., technical session; evening, informal smoker and popular addresses.

Wednesday, Oct. 30—10 a.m., technical session at Statler hotel. Afternoon: Trip. 7:30 p.m.: Subscription banquet, members and guests, including ladies.

Thursday, Oct. 31—10 a.m.: technical session at Case School of Applied Science. Afternoon: Trip. Evening: Unassigned.

The meeting is primarily one of the Iron and Steel Division of the Institute, and 18 papers dealing with iron, steel, and related topics will be presented. Sixteen papers on general topics and ten papers presented at the Eighth International Congress of Applied Chemistry will be submitted. Most of these papers will be read by title, but a large number will be presented by their authors.

## Publicity and the Press

In accordance with the Act of Congress, August 24, 1912, referred to editorially in our issue of September 21, we take pleasure in publishing the following:

Statement of the ownership and management of the *Mining and Scientific Press*, published weekly at San Francisco, California.

Name of	P. O. Address.
Editor—H. FOSTER BAIN.	San Francisco, Cal.
Managing Editor—H. FOSTER BAIN.	"

Notary Public.

Coalfields of Wind River Region

The coalfields of the Wind River region, in Fremont and Natrona counties, Wyoming, are discussed in detail in Bulletin 471-G of the U. S. Geological Survey. The primary purpose of the investigation was to obtain data for the classification of the public land and to collect information relating to the amount and character of the coal in order to fix a price at which such land should be offered for sale. The Wind River coalfields comprise an area of about 2500 square miles and include the geographic centre of Wyoming. This region has been known to contain coal of commercial value since some of the earlier explorers examined coal beds along Popo Agie river. Only small mines were opened, however, because the sparse settlement afforded very little local market and there was no commercial market which could be reached until 1906, when the Wyoming & Northwestern railroad was completed from Casper to Lander.

The coal, which is a low-grade bituminous coal, when reduced to a coarse powder is black, but when crushed to a very fine state is dark brown. It burns with a short red flame, ignites readily, and produces ash not inclined to clinker. When burned in a stove the coal does not fuse and shows no tendency to coke. The Wind River coal is best adapted for domestic fuel, but it has been employed satisfactorily under stationary boilers, in limekilns, and in similar places where forced draft is not required. Owing to the rapidity with which it disintegrates, the coal must be shipped in box cars and can be held in storage only a short time after it is mined. This results in mining only in winter, when fuel is needed for immediate use, and when mining is more difficult and expensive than in summer. The market for coal in the Wind River region is limited to a few towns along the railroad and to widely separated ranches in the area. Consequently the product of the large mines must be shipped to places reached by railroad outside of the region. In these markets, however, the coal is brought into competition with that from other fields in Wyoming and in Iowa, where mining conditions are generally more favorable or where a better grade of coal is obtained.

Copper Producers' Association Report

The Copper Producers' Association statement, October 8, shows an increase during the preceding month in accumulation in this country of 16,364,213 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, Sept. 1, 1912	46,701,374
Production of marketable copper in the United States from all domestic and foreign sources during September	140,089,819
Deliveries for consumption, September	63,460,810
Deliveries for export, September	60,264,796
Stock of marketable copper of all kinds on hand at all points in the United States, October 1.	63,065,587
The changes in surplus since October 1, 1911, have been as follows, in pounds.	
	Increase.      Decrease.
October, 1911	5,897,214
November	23,212,454
December	22,330,493
January, 1912	22,173,252
February	3,301,944
March	572,431
April	2,927,829
May	15,450,386
June	5,280,639
July	5,945,416
August	3,579,046
September	16,364,213

Gold Placers Near the Yukon

The town of Eagle, on the Yukon, 30 miles above the eastern boundary of the region, and Circle, on the Yukon 30 miles below its western boundary, are the nearest settlements to the gold placers in the basin between Woodchopper and Fourth of July creeks, Alaska, on the Upper Yukon. The northern part of this region is readily accessible from the Yukon, but in the parts that are remote from the river the means of communication are still very primitive. Trails and winter sled roads lead up most of the principal creeks.

Mining was probably done in the region as early as 1898, but the most important developments have been made during the last six or seven years. The total gold production of the region is less than \$150,000, the greater part of which has come from Mineral gulch, a tributary of Woodchopper creek, and from Fourth of July creek. Last year about 30 men were engaged in placer mining on the creeks in this region.

Auriferous gravels are distributed over a considerable area along Woodchopper creek, but no rich or extensive deposits have been found. The relative accessibility of the placers to the Yukon is favorable to cheap mining, but only a small amount of water is available for sluicing. With one exception, all the operations have been of a primitive type. A steam-shovel on Fourth of July creek and a few steam hoists are the only machines employed. These deposits are described in Bulletin 520-G of the U. S. Geological Survey.

Alleged Chemical Effects of Pressure on Mineral Metamorphism

Giorgio Spezia, in the *Atti acad. sci Torino*, 46, 682-98, criticizes Van Hise's views on the influence of pressure on the dehydration, deoxidation, and silicization of minerals in the zone of 'anamorphism' (U. S. Geol. Surv. Monographs, Vol. 47). As dehydration under pressure is conceivable only if the hydrated mineral is surrounded by an anhydrous mineral with minute pores into which the water squeezed out can penetrate, samples of rock alum, alabaster, and limonite surrounded with well dried quartz powder were subjected for eight months to a pressure of 8000 atmospheres at 15 to 24°. After this treatment the limonite still gave off much water when heated in a tube and when powdered had the yellow color of iron hydroxide, while analysis showed that the alum and alabaster had lost practically no water. The great influence of temperature, on the other hand, is shown by the fact that these two minerals can be completely dehydrated at 100°C. and that the alabaster is dehydrated in water in an autoclave at 150°C., and limonite at 330°C. Goethite, containing 10.16% H<sub>2</sub>O, lost no water after 26 days under 9500 atmospheres at 15°C. with quartz powder, while after 7 days with water at 320 to 330°C. it contained only 0.13% H<sub>2</sub>O. Similarly, deoxidation under pressure is conceivable only if another mineral with a greater affinity for O is present, yet no chemical reaction took place when CuO mixed with Mg filings or with K was subjected to 9500 atmospheres pressure at room temperature for 30 days, although the sum of the molecular volumes of CuO and Mg (or K) is greater than that of Cu and MgO (or K<sub>2</sub>O). Van Hise's division of minerals, based on pressure, is untenable. To test his statement that at very great depths calcite (d. 2.72) should change into aragonite (d. 2.92), powdered Iceland spar and aragonite, separated by a disc of lead, were placed in the same apparatus and subjected to a pressure of 7000 atmospheres for 6 months at room temperature. The resulting cylinders were then powdered and treated by the Meigen method; on heating with Co(NO<sub>3</sub>)<sub>2</sub> the calcite remained perfectly white and the aragonite assumed the characteristic violet color.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Effect of Copper on Steel

The Editor:

Sir—The item in your New York correspondence in the issue of August 24 relating to the discovery that the unusually good wearing qualities of certain rails on the New York, New Haven & Hartford railroad was presumably due to the fact that the steel used contained  $1\frac{1}{4}\%$  copper, is interesting in the light of some recorded experiments with the use of copper as an alloy of iron made about 1910 under the direction of C. F. Burgess at the University of Wisconsin laboratories. Mr. Burgess, collaborating with James Ashton under the auspices of the Carnegie Institute of Washington, conducted an illuminating series of tests of the alloys of nickel and copper with electrolytic iron. Regarding the copper-iron alloy the report says:

"Our results and comparisons would indicate that the copper-iron alloys are also worthy of consideration and might be comparable to the nickel steels in use, even if the strength should not reach such high values as those of the nickel. A  $1\frac{1}{2}\%$  copper alloy is of promise, since the smaller percentage required and the lessened cost per pound of copper as compared with nickel would result in a lessened cost of construction, even if there is some increase in tonnage required because of the slightly decreased strength per equal weight."

Other investigators have made interesting tests of alloys of copper and steel. Notable among these is Pierre Breuil, who in 1907 made an effort to see if there was a beneficial effect due to the addition of copper to steel suggested by the favorable influence of copper on steels for railway axles, which was noted on some of the French railroads. Breuil mentions the 4% copper alloy with mild steel as worthy of further study, and generally confirms the claim that certain copper-steel alloys are of commercial advantage.

Your correspondent has effectively made the most of the incident from the copper-market angle, but there remains the consideration that the acceptance of the beneficial effects of small amounts of copper in iron and steel will be a relief to some of the owners of iron mines in which copper is found as a minor impurity, and to the producers of pyrite cinder and other iron by-products in which the presence of copper in small amounts is sometimes unavoidable.

KIRBY THOMAS.

New York, September 5.

### The Measure of Precision

The Editor:

Sir—Being a subscriber to the *Mining and Scientific Press*, I have read your editorial entitled 'The Measure of Precision,' published in the issue of June 22. In this you make certain statements concerning my paper, 'Illogical Precision in Mine Reports,' which has been read before the Institution of Mining and Metallurgy. I do not mind how severe a criticism is, provided it be reasonable and to the point; but I do take exception to the hasty remarks in your article on a portion of the subject which you have palpably misunderstood.

In the article you have copied the following sentences from my paper: "Lode-widths are usually measured to the nearest inch, so that it is mathematically incorrect to calculate the average width to anything less than a whole inch." "The writer has not been able to find this principle definitely stated as a law in a mathematical text-book, but it would appear only a matter of common

sense that, in determining the mean of a number of quantities, the result should be expressed to the same degree of accuracy as that observed in measuring the several quantities." Then follows your intemperate tirade, enlarging on a totally different principle to that expressed in the above sentences.

You have put yourself to much trouble in quoting authorities who prove that by making several determinations of the same measurement, the mean of these can be expressed to an accuracy which is greater than that observed in making the several determinations. Unfortunately, this axiom has no bearing on my paper, as it deals with *multiple* determinations of the *same* measurement; whereas the principle stated in my paper relates to calculating the average of *individual* determinations of *different* measurements, all of which are observed with admitted approximation to accuracy. I hope you will acknowledge the difference.

In my paper it is stated that I do not know of any mathematical text-book which treats of this phase of averaging measurements, and I repeat that statement here; nor have you had the satisfaction of finding any such book for me. But you have indeed given to the world a most interesting piece of news by stating that Laplace's 'Philosophical Essay on Probabilities' was published in 1744. This happens to be five years previous to the birth of the author. For your information I will add that Laplace was born at Beaumont-en-Auge on March 28, 1749, and the publication of his 'Philosophical Essay on Probabilities' was commenced in 1812, although it is known that he gave a course of lectures on the subject some years previously. Writing "nonsensical flapdoodle"—to use your own proud phrase—would seem to be a contagious complaint.

F. PERCY ROLFE.

Langlaagte, Transvaal, August 12.

[We are glad to accord Mr. Rolfe the space he requests, since he feels he has been misrepresented. But the distinction sought between multiple determinations of a single measurement and the average of individual determinations of different measurements is no more illuminating and serviceable than that between tweedledum and tweedledee. The average value of a variable quantity is as definite an entity as the exact value of any other quantity; the length of a line, for example. The laws governing the exact determination of either have been well understood by mathematicians for many years, and it would be well if they were more generally understood by engineers of the present day. Mr. Rolfe naturally does "not know of any mathematical text-book which treats of this phase of averaging measurements," just as he does not know of any astronomical text-book which treats of the possibility of the moon being composed of green cheese. In other words, the distinction sought is no distinction at all, as is evident from a moment's logical thought.

The date given for Laplace's work, though erroneous, is not misleading, being merely intended to indicate that so long ago as the middle of the eighteenth century the logic of probability was well developed. By that time more than a dozen authors, among them Huygens, the Bernouillis, and De Moivre, had contributed to the discussion of the topic which Laplace later so admirably summarized. Laplace's 'Mémoire sur la Probabilité des causes par les Événemens' is confused, in the only reference work at hand at the time of writing, with his 'Théorie Analytique des Probabilités,' 1744 being a misprint for 1774, the date of the former work.—EDITOR.]

SHIPMENTS of coal from New South Wales last year amounted to 5,024,080 tons, valued at \$12,947,968, as against 4,690,433 tons, valued at \$11,951,498, for 1910. There was 2,498,304 tons, valued at \$6,587,735, of coal shipped to over-sea ports, an increase of 286,368 tons and \$747,614 in value over the preceding year. Exports to Australasian ports were 2,525,776 tons, valued at \$6,360,233, an increase of 47,279 tons and \$248,856 in value over 1910.

## Special Correspondence

### BLACK HILLS, SOUTH DAKOTA

HOMESTAKE PROSPEROUS.—WORK OF THE WASP NO. 2.—  
COLUMBUS CONSOLIDATED.

A local paper is authority for the statement that the month of August was a record breaker for the production at the Homestake. During that month 21 bars of bullion were produced, an amount in excess of the usual production. This is stated to be due to higher grades of ore mined on the lower levels. For a year or so it has been quite generally known that some of the richest ore ever found in the Black Hills was being taken from the workings on the deep levels in the Ellison. During August more of this class of ore was milled than usual. It has been the custom of the company for years to maintain the average value by treating each month a small amount of high-grade ore. During the past month the work on the construction of the new recreation hall and club building for Homestake employees, the gift of the company to its men, has been pushed. Foundation work is well in hand, and the structure will probably be enclosed before cold weather sets in.

During the quarter ended September 30, L. P. Jenkins, assayer in charge of the U. S. assay office at Deadwood,

NORTH HOMESTAKE MILL.

reports bullion purchases to have been \$1,988,814. This is the largest quarter of the year, and very nearly equals the largest quarter's business ever done by the office. Milling operations have been suspended at the Black Hills Standard property and will not be resumed before spring. The mill building was in such a poor state of repair, after ten years' disuse, that it was decided not to attempt to repair it at this time. In the meanwhile work is being carried forward at the mine, and by the time the mill is in operation again the mine will be in still better shape. The Victoria mill is operating steadily, handling over 100 tons of ore per day. It is hoped to increase the tonnage to 200 per day with the present equipment, which will be in excess of the rated capacity of the plant at the time it was built. O. N. Brown, Cyanide, South Dakota, is manager.

The Wasp No. 2 company is paying 2c. per share per month dividends. Steam-shovel stripping is being pushed, as it is planned to shut the shovel down during the winter months. At the present time 35,000 tons of ore is stripped, practically four months' supply, from that portion of the property where the shovel is used for stripping. On the south side, where hand labor is used in stripping, there is a smaller quantity uncovered, and it will probably be necessary to continue stripping through the winter on this part of the property. The Bismarck mill, adjoining the Wasp No. 2, is being rapidly completed, and should be in operation within two months, according to F. B. Hitchings, the general manager. The superstructure is completed, and the tanks set up. About all that remains to be done is to install some of the machinery and make final adjustments. Orders have been placed for all of the needed equipment, and it will be erected as rapidly as received. A consolidation of the Deadwood Homestake, owned by C. E. McHugh,

the Montezuma and Whizzers, owned by Carpenter and Gillmore, and the Garfield, owned by Clara D. Coe and associates, is announced. The properties adjoin the Homestake on the east and northeast. It is proposed to sink a shaft 1000 ft., close to the Homestake boundary, in anticipation of cutting some of the Homestake orebodies.

The Homestake company is acquiring the Columbus Consolidated as fast as the necessary legal papers can be signed and delivered. The purchase involves taxes, liens, and judgments amounting to about \$30,000, and a payment to bondholders of 5% for the bonds outstanding. This purchase, with the Hidden Fortune, which was taken over recently, gives the company an additional 1000 acres of ground, making a total of close to 4000 acres along the strike of the orebodies, held by the company. The last two purchases were made at exceptionally low figures, and were possible through internal troubles, resulting in litigation and suspension of operations by the original companies.

### WASHINGTON, D. C.

LEASING OF WYOMING COAL LANDS.—CONTROL BY BUREAU OF MINES.—AMOUNT OF ROYALTY.

Leasing of 2480 acres of public coal land in Wyoming to the Owl Creek Coal Co. marks an important development in the policy of the Federal Government in regard to the public lands, and the leasing system is likely to develop extensively. Van H. Manning, assistant to J. A. Holmes, director of the Bureau of Mines, has gone to Wyoming to complete the negotiations between the company and the Government. The Bureau of Mines will have control of the methods of mining and the safety precautions taken to safeguard the men and prevent wasteful mining, according to the terms of the lease, as approved by W. L. Fisher, Secretary of the Department of the Interior.

The lease, which is signed by Samuel Adams, as acting secretary of the Interior Department, and Rufus J. Ireland, president of the Owl Creek Coal Co., provides that the company has the right to mine coal from 2480 acres of land at Lander, Wyoming, for a period of thirty years. The lease proper is for ten years, the company to have preferential right of removal for successive periods of five years each up to a total of thirty years on terms to be fixed by the Secretary of Interior at or before the beginning of each five-year period.

The company agrees that it will pay at the beginning of the lease and on July 1 of each succeeding year, \$2480, or \$1 for each acre in the lease, which is to be credited upon the royalties due under the lease. The company agrees to pay on the production of all coal mined a royalty on each ton of 6½c. for the first five years and 8c. per ton for the next five years. The royalty thereafter is to be fixed by the Secretary of the Interior at the beginning of each five-year period. The company further agrees that it will operate its mines with "reasonable diligence, skill, and care, in compliance with any and all rules and regulations now or hereafter promulgated by the Secretary of the Interior for the purpose of safeguarding the health and lives of the miners and employees and of preventing the unnecessary waste of coal."

Still further the company agrees that all mining operations shall be subject to the examination, inspection, supervision, and direction of the Bureau of Mines. The company must not assign the lease or any interest in the premises; it shall not permit traffic in intoxicating liquors on the property; and at the end of the lease the property must be surrendered in good condition. All debris from the mine free from coal shall be deposited separate from waste containing coal, and no such waste shall be deposited in the bed or margin of any stream. The Secretary of the Interior has the right to forfeit the lease for any violation. The lease closes with the following clause: "No member or delegate to Congress, or resident commissioner, after his election or appointment or either, before or after he has qualified and during his continuance in office, and no officer, agent, or

employee of the Government, shall be admitted to any share or part of this contract or agreement, or to any benefit to arise therefrom."

### LONDON

#### EL ORO OUTPUT.—INTEREST IN RAND MINES.—NEW MODDERFONTEIN REPORT.

During his visit to Mexico in December last, R. T. Bayliss sent home some unpleasant news concerning the probable future of the El Oro gold mine. He announced that the stopes in the upper portion of the San Rafael vein could not maintain the current output of ore for more than three years. In order that a regular output might be maintained for a sufficiently long time until the deeper levels are explored and developed on a large scale, he recommended a reduction in the rate of extraction of the ore. The results of this policy are shown in the report for the year ended June 30, 1912. The net realized profit was £182,149, as compared with £216,430 during the previous twelve months, and the dividends totaled £143,437 as compared with £172,125. The amount of ore treated was 302,698 tons as compared with 360,294 tons. In addition, 84,459 tons of accumulated sand tailing was re-ground in the tube-mills and sent to the cyanide plant. It was decided to start the re-treatment of this tailing in order to maintain the tonnage passing through the tube-mills and vats. There still remains 378,279 tons of this material. The assay-value of the ore treated was \$6.36 gold and \$1.30 silver, and of the tailing re-treated \$2.68 gold and \$0.88 silver. The bullion realized £454,582 and the mining expenditure was £299,222. A profit of £23,868 was made on the railway; London expenses and directors' fees were £5006, and £25,000 was written off the value of plant. It is estimated that the ore reserve on June 30 was 301,934 tons, averaging \$7.46 gold and 3 oz. silver per ton, as compared with 484,139 tons a year ago. A. F. Main, the manager, gives details of the exploration and development work done during the year. Unexpected discoveries of ore have been made in the upper portion of the south end of the mine, and the results obtained by the further development of the Branch vein on the 1150 and 1300-ft. levels are sufficiently encouraging. On the 1450 and 1600-ft. levels not enough work has been done to justify any expression of opinion. The mill is now regularly treating 20,000 tons of ore and 15,000 tons of tailing per month.

For some years the speculative interest in mines on the Rand has been decidedly restricted, for the new developments have been in connection with either old mines in depth or old outcrop mines that have hitherto been unprofitable. The great expansion of the work in the far east Rand has not been taken quite seriously. The deposits here are flat and of comparatively low grade. There has been no opportunity for enrichment by surface weathering such as characterizes the deposits on the central Rand where discoveries were first made thirty years ago. It is noteworthy, therefore, that the speculative interest in Rand doings is being awakened once more by the good results shown by many of these mines in the far east Rand. In the early days, a quarter of a century ago, C. J. Alford urged the desirability of exploring for gold in this district. Outcrops of coal had been found there, and the deposits have since then been continuously worked, providing an invaluable source of fuel for the gold mines. But at that time Mr. Alford's views were scouted by capitalists, and knowing that the evening of his life is being spent in conditions far removed from affluence, it is opportune to remark that his case affords another example of a conscientious and well informed technical man not receiving his full deserts in this world. At the present time there is much discussion on the Rand as to the continuity of the various deposits, and the actual geology of the district between the big bend of the outcrop southward at Boksburg and the Heidelberg deposits, 15 miles south, has formed the subject of many a battle royal

among geologists, not to say also the pseudo-geologists. The Van Ryn may be called the pioneer gold mine of the far east Rand. For years the low grade and irregular content of the surface deposits there caused trouble to the capitalists, and the income was not equal to the expenditure. As already mentioned, the flat outcrop had not the common surface enrichment which usually provides the capital and experience in a new goldfield. Later G. A. and H. S. Denny, as consulting engineers to Albu Brothers, effected many improvements in development, mining, and surface treatment, and the Van Ryn has since become a valuable property. As regards other mines in this district, I need not recapitulate here what I have written from time to time during the past three or four years about the Brakpan. The development of this mine has been in the hands of W. L. Honnold, one of the few Americans left in South Africa. This mine is in close proximity to the overlying coal deposits, and coal is at present being hoisted from points on the dip of the auriferous conglomerate not far away horizontally from the Brakpan workings. I have also mentioned the Kleinfontein and Benomi mines on the outcrop, in connection with metallurgical discussions due to E. J. Way's refusal in the first case to progress with the times in tube-mill practice, and in the second case to his decision to erect a treatment plant on a large scale employing a system not fully proved. I have also mentioned the attempt to consolidate the Benoni and Apex. The most important advances at the present time that have led to an increased interest in the far east Rand are in connection with the four Modderfonteins, namely, the New Modderfontein, the Modderfontein B, the Modderfontein Deep, and the Government Gold Mining Areas (Modderfontein). The two first-named belong to the Central Mining group, the third to the Goerz group, and the management of the fourth, under government control, is with the Barnatos. The results at the New Modder and Modder B are already profitable, and at the former the increase in the output, profits, and ore reserve is most noticeable. The results of the last years operations are in the following paragraph. At the Modder Deep and the Government Gold Mining Areas the work is at present confined to shaft-sinking. At the first-named the vertical shaft cut the deposit at 2990 ft., where the lode is 10 ft. thick, averaging 8.8 dwt. The two shafts sunk by the Government Gold Mining Areas have not happened to strike good quality ore; at the first the lode was 2½ ft. thick, averaging 7 dwt., and at the second 20 in., assaying 4.7 dwt. There is no special reason for discouragement, for the auriferous deposits on the Rand vary in width and content to an extent not generally admitted or recognized by people unacquainted by actual experience. The total area covered by these flat lodes covers quite ten square miles, so that the potential value of the deposits is of the greatest importance.

To give an idea of the actual results achieved in this district, I cannot do better than reproduce the figures contained in the yearly report of the New Modderfontein for the year ended June 30 last. During the year 657,806 tons was raised and, after the rejection of 11% waste, 585,900 tons was sent to the mill. The extraction by amalgamation was 184,081 oz., and by cyanide 56,901 oz., making a total yield of 240,982 oz. There are 180 stamps and 7 tube-mills. The assay-value of the mill-feed was 35s. 5d., and of the final residue, 9d.; the yield was therefore 34s. 8d. per ton, or 97¾% of the estimated content. The income from the sale of gold was £1,011,020, and the expenditure was £546,960, leaving a profit of £464,059, or 15s. 10d. per ton. The amount of ore treated was 47,500 tons greater than during the previous year, and the yield per ton was 5s. 1d. greater. On the other hand, a scarcity of native labor during the last few months of the financial year caused the average cost per ton to increase from 17s. 4d. to 18s. 8d. By concentrating operations over a more limited area, it has been possible since the close of the year to obtain better results with the limited labor force

at disposal. The reserve on June 30 stood at 3,900,000 tons, averaging 8.1 dwt. gold, as compared with 3,341,830 tons, averaging 7.6 dwt. the year before. The revenue account for the year under review shows that £17,781 was spent on capital account on undermining rights, and £41,469 on new plant and shaft-sinking, while £43,152 was paid as government tax. The dividends absorbed £350,000, being at the rate of 25%. Since the formation of the company the yield of gold has been worth £4,915,642, and the dividends have totaled £1,247,500.

### NEW YORK

GRANBY REPORT.—PHELPS-DODGE ACTIVITIES.—INCREASED DIVIDEND SPECULATION.

The annual meeting of the Granby Consolidated was held on the first of October. The number of directors on the board was reduced from 15 to 13 by the retirement of A. L. White and Arthur Curtiss James, the latter having resigned some months ago. W. H. Nichols was elected president of the company, succeeding George Martin Luther. The report of the year's operations shows that during the eight months when the property was operated 13,231,000 lb. of copper was produced, at an averaged cost of 11.1c. and a net profit of \$583,378; which, however, was not carried forward, as \$600,000 was written off for depreciation,

GRANBY SMELTER, GRAND FORKS, B. C.

resulting in a deficit of \$17,184. The developed ore is now estimated at 6,463,433 tons, as compared with 6,720,294 tons a year ago. At the present time Granby is producing at the rate of about 20,000,000 lb. per year and, at the present copper price of 17½c., can earn about \$100,000 per month. The most important matter taken up at the meeting, but not definitely decided, is the question of the financing of the Hidden Creek mine. The Hidden Creek is now considered of more importance than the older property at Phoenix, but it has so far been developed out of the earnings of the Granby. If this method is continued it will be necessary to withhold dividends; while, on the other hand, the public would undoubtedly be glad to take a convertible bond issue, which would provide ample funds to develop some five million tons of ore containing 2.3% copper, nearly twice as much in copper content as the average of the Granby ores. The new plant is expected to be in operation by the end of 1913, a good deal of preliminary work having already been accomplished in the building of a wharf and grading both for wagon-roads and the railroad. J. P. Graves estimates that at Hidden Creek copper can be produced at not more than 8½c. per pound.

The Moctezuma mine of the Phelps-Dodge company at Nacozari has resumed shipments, and the first load of concentrate delivered for a month arrived at Douglas this week. The Phelps-Dodge production for the month will show a marked decrease owing to the interruption of shipments, though the mill at Nacozari lost no time, but accumulated a stock of concentrate that can now be forwarded. The Consolidated Arizona Smelting Co. is ex-

pecting to blow in its new 150-ton smelter at Humboldt, Arizona, by November 1. Consolidated Arizona had a long market career and has been the medium of some spectacular market turns, but as a mining venture it has not been a startling success. Yavapai county, in Arizona, is to the investor or share-buyer in the East one of the best known mining districts in the United States, but it unfortunately does not muster any large number of successful ventures. The final decree of dissolution has been entered concerning the Chemung Copper Co., and a distribution of assets in final liquidation is all that remains to be done. The cash balance in the treasury amounts to \$1,231,072, which will give the stockholders about \$6.16 per share.

Our own group of copper magnates, while the most important in the industry, is not the only syndicate of some pretensions as factors in the metal market. A copper syndicate has been operating in Russia since 1907, and now controls over two-thirds of the Russian output. Some justification for the claims of the copper people as to the

COPPER QUEEN POWER-HOUSE.

vastly increased consumption of the metal is found in a study of the Russian copper industry. Since 1907, production in Russia has increased from 14,300 tons to 25,000 tons in 1911. Consumption, however, has also made great strides, increasing from 23,100 tons in 1906 to 30,700 tons in 1911. Russia's mineral resources are largely undeveloped and a great deal of English capital is being invested in the development of Russian mines.

The speculation regarding increased dividends to be paid by the Guggenheim companies is partly set at rest by the semi-official announcement that no move of this kind will be made until next April, when it is expected that Ray and Chino will arrange for initial disbursements, and Utah double its present dividend rate. Nevada Consolidated's fiscal year closes with the calendar year, and a distribution of the present cash surplus in the Nevada Consolidated treasury in the form of an extra dividend is anticipated. Market speculative interest in copper is centred in Amalgamated, and now that Anaconda's distribution has been raised, market followers will be deeply disappointed if Amalgamated is not placed on a 6% basis. The 'Street' is firm in the belief that Amalgamated is to be sold at par before the present movement is over, and thereafter the dissolution of Amalgamated will be looked upon as an important possibility.

Mason Valley is acquiring an increased market following since the smelter capacity has been increased by the blowing in of the new 900-ton furnace. The old furnace is to be enlarged to 35 ft. in length, when it is expected that 2000 tons of ore can be handled daily by the two. The smelter management is able to get a fluxing mixture from the

various ores handled, and has put 917 tons of ore through the old furnace in one day. The Phelps-Dodge output for September was 11,757,372 lb., as compared with 15,152,558 lb. in August, the decrease being due to the interruption of shipments from Nacozari. The Pittsburg & Mt. Shasta Gold Mining & Milling Co., a property which is nearly completely owned in and around Pittsburg, is holding a special meeting this week for the purpose of voting on an increase in capital stock from \$1,000,000 to \$1,500,000.

South Pass, Wyoming, made its first bid for publicity many years ago, when 'Mark Twain' described his journey through the pass by stage coach. Of the mountains encircling South Pass, Clemens wrote: "These sultans of the fastnesses were turbaned with tumbled volumes of cloud, which shredded away from time to time and drifted off fringed and torn, trailing their continents of shadow after them; and catching presently on an intercepting peak, wrapped it about and brooded there, then shredded away again and left the purple peak as they had left the purple domes, downy and white with new laid snow." The South Pass country and the Wind River mountains have always been known as one of the most fascinating parts of the Rocky Mountains, and the prospector has lingered there for many years in the hope of finding something worth while. South Pass mining properties have been offered to the public for more than forty years, but results have never justified any great degree of enthusiasm as to the district's mineralization, however much in accord one might be with the humorist's splendid description of its snowy heights. The telegraphic despatches of the day carry news of a discovery in the Hidden Hand mine, near South Pass, of \$60,000 ore, and of a freight train of seven wagons carrying 25,000 lb. of ore averaging \$2000 per ton. To quote another line from 'Mark Twain,' "I am not given to exaggeration, when I say a thing, I mean it." Seriously, though, the Eastern markets would welcome the advent of a new precious metal district, with something in the way of mineralization that would justify inspection and development. It is useless to attempt to conceal the desperate plight of the New York mining market. With almost no public following, traders are reduced to that condition technically known as a wholly professional market; perhaps better described as a case of 'dog eat dog.' If South Pass or Terra del Fuego could enlist some public interest, either would be impartially and wholeheartedly welcomed in New York.

## BOSTON

DETAILS OF THE DOW FAILURE.—DOW'S CAREER.—CLEANING UP BOSTON.

The district attorney has started an investigation of the failure of Stephen R. Dow & Co., and it is quite probable that the matter will result in a bill of indictment against the young broker who has played fast and loose with the funds of his companies. Dow has had a sensational career, having started out but a few years ago as stock clerk in a brokerage house. He is just 40 years old and is one of the 'nerviest' stock plungers Boston has ever had, not forgetting Thomas W. Lawson and Jesse Livermore. Dow entered the copper-mining field in connection with the enterprises of Harry F. Fay, president of Old Colony and late president of Mayflower. He first attracted notice as president of the Franklin Copper Co., which he has brought to a producing stage. He then formed North Lake, Indiana, and Algomah, in the Lake Superior district; Corbin, in the Corbin district of Montana; and the Arizona Mines Co., of Arizona. While he was bringing all these issues forth on the Exchange and Curb, and making them in almost every instance leaders in trading activity, he was identified with Adventure, Elm River (now known as Contact Copper), Mayflower, and the Union Copper Mine & Land Co. as director. Dow was in the height of his prosperity in the early part of 1910, when he boomed Indiana and North Lake, both of them at the time drill-core prospects, up to \$44.75 and \$25.67½ per share, respectively.

Although it is not believed that Dow succeeded in distributing much of the stock of these companies, and was, in fact, afterward embarrassed more than helped by keeping up their quotations, he attracted attention throughout the country as a bold and resourceful operator. He did not hesitate at times to express his contempt for the slow-going methods of other copper manipulators, who, on the news of a discovery made at their properties, would fail to move the stock up a few points. Dow was in the habit of saying that it did not take much of a development item at one of his properties to send the stock up five or ten points. Yet with his reckless adventures into the stock market he was regarded as a very thorough man in the handling of his mining properties. He insisted upon full reports and the news of development being promptly despatched to the home office. Inquirers after conditions at any of his mines were said to have always found him ready to give them any desired details. After the Indiana and North Lake boom, Dow received a severe blow by the St. Mary's Mineral Land Co. distributing Franklin stock to the land company stockholders in payment for land the company had sold to Franklin. As this stock amounted to 32,000 shares and found its way, to a large extent, into the market, it forced the price of Franklin down from above \$20 to \$10 per share. As Dow & Co. was a large holder in Franklin, this crippled the firm.

In the middle of 1910 Dow had another serious financial problem put up to him when Algomah was floated. It cost him \$150,000 to make peace with some of the original owners of the land. His undoing seems to have dated from August of last year, when it became necessary for a group of Boston banking houses to advance him about \$100,000 to tide over his firm, at the same time securing the consent of twenty banks holding Dow collateral to refrain from any sudden liquidation of these securities. In the past year most of these old loans have been liquidated. It is possible that the Dow failure may yet reach approximately half a million dollars, involving principally the Franklin, Indiana, North Lake, and Algomah companies, and a few of the members of the Stock Exchange. It was thought, immediately following the failure, that Mr. Dow had left town, as he could not be found, but this did not prove to be the case. He is standing his ground, holding that he acted within his rights in borrowing from the companies which his house represented as fiscal agents. These companies are said to have borrowed from him in turn. Mr. Dow received a salary of \$5000 per year from each of five companies—Franklin, Indiana, North Lake, Algomah, and Corbin—and his firm occupied an entire floor of the new Stock Exchange building of Hornblower & Weeks. Franklin and Indiana have already called assessments to make up the shortage created by Dow's cleaning out their treasuries. Franklin's call is for \$2 and Indiana's for \$1 per share. Algomah is expected to take similar action later. Corbin does not sustain any losses, as the company was itself a borrower. The South Lake company directors have felt it necessary to make a statement explaining that their company did not suffer by the Dow failure, as it has not made any loans to Mr. Dow or anybody else. It is claimed that the by-laws of the copper companies admitted of the loans being made to Dow without requiring sanction on the part of the board of directors. There is a technical question as to the guilt of Mr. Dow from a legal standpoint, but the extent of their losses and the flagrant character of the case is causing many stockholders to clamor for criminal proceedings. The district attorney, who recently contested the nomination for governor of Massachusetts, but was unsuccessful, has been charged with playing politics in the great activity his office has shown against the Boston Elevated Co. and the heads of the American Woolen Co. But he says now that he is going to probe the Dow failure to the bottom, and has also intimated that the Stock Exchange will be investigated and ventilated also. It is certain that Boston has not had a more deplorable failure in financial circles in the past ten years.

## General Mining News

### ALASKA

#### FAIRBANKS

The output of the Koyukuk district should reach \$230,000 this season. About 350 men are in the country, and all are doing fairly well.

#### NOME

The *Nome Weekly Nugget* states that over 100,000 people have traveled between Nome and Seattle since the first gold discovery. The total number of claims staked and filed in the Nome office is 56,600, but the deputy recorder says that about 15,000 of such instruments filed were not locations. Claims recorded in the Teller district total 8000, Kougarak about the same number, and the Council district probably 12,000. The shipments of gold for this year from Nome are practically the same as last year, and the general tonnage of supplies exceeds last year, to date being 18,865 tons.

The Kimball dredge, on Shovel creek, has worked into rich ground. There is more activity right through the Council district this season than last. The steamer *Mackinaw* left Teller with \$60,000 of tin ore, shipped by the York Dredging Co. The dredge was built during last summer and then recovered tin worth \$48,000. This is shipped to Liverpool, England. Tin from Buck creek is worth \$575 per ton. The American Goldfields Development Co. has taken an option on 3500 acres of ground on Cripple river, and is now prospecting the area by drilling. It is stated that four or five new dredges will be built in the Keewalik and surrounding districts next season, one dredge being on its way up from Seattle. The Keewalik Mining Co. has four nozzles working on Johnny Bull hill, two being 3½-in. size. The clean-up is expected to be at least \$25,000. The Candle Creek Mining Co.'s dredge is working well. Seventy-five tons of graphite ore will be shipped out from C. E. Christofferson's mine, near Teller. A large tonnage is said to be exposed. The Lange mill of six stamps will be built at Bluff this fall or next spring. Near Nome the New Era Mining Co. has a 4-stamp mill at work, and recently cleaned up 91 oz. of gold, which exceeded expectations. An adit has been started 75 ft. from the mill, and is in 50 ft.; it should cut the vein at 200 or 300 ft. at a depth of 400 ft. The claim of C. Goodmanson has a vein 6 ft. wide assaying \$22.50 per ton. The *Nome Weekly Nugget* is issuing a third edition of its Mining and Dredging issue.

#### VALDEZ

The inhabitants of Seward have been worried of late by possible danger from Lowell creek, which threatened to overflow the town. There have been unusual quantities of water flowing through the channel. Game is reported to be very scarce in the hills this season, this being attributed to the eruption of Mt. Katmai, which distributed a large quantity of ash over the Kenai peninsula.

### ARIZONA

#### COCHISE COUNTY

The Shattuck- Arizona will increase its employees by over 100, but skilled men are hard to get. It is intended to start shipping ore to one of the Douglas smelters. The Junction shaft of the Calumet & Arizona is 1800 ft. deep, and it has been decided to concrete it from the surface down to 1500 ft. Concrete will be mixed at the surface and run down into the forms through pipes.

#### GILA COUNTY

(Special Correspondence.)—In September the Miami Copper Co. mined and milled 90,000 tons of ore, producing concentrate which will yield about 2,790,000 lb. of fine copper. The mill recovery was about 70%. Three 8-ft. Hardinge pebble-mills are on the road, and they will replace the Chilean mills in the second unit, making four of the six units to be thus equipped. Exploration and

development of the northeast part of the property by two churn-drills continues, and the ground below the 570-ft. level is being explored by diamond-drilling, four holes having been put down to date. At No. 4, or main shaft, foundations are being laid for the new change-house, the new machine-shop is being equipped, and the new mine and engineering office is being finished inside. The construction of the Miami-Inspiration hospital is well under way. About 1000 men are employed.

The main east shaft at the Inspiration Consolidated mines was 305 ft. deep on October 1, and the main west shaft 435 ft. deep, and sinking continues steadily. Development work at the Inspiration mine is confined almost entirely to opening up the first haulage-level, and 3800 ft. was done in September, compared with 4900 ft. for August. The decrease was due to the fact that much of the September work consisted in widening to working size and timbering the drifts previously driven. There was an increase in the amount of work done, there being now 240 men working underground. At the Live Oak mine, driving from No. 2 shaft on the 570-ft. level continues, No. 1 shaft is being sunk, and the sulphide adit is being widened for electric haulage. McArthur Brothers are using a steam-shovel and employing about 250 men in grading for the railroads. At South Live Oak, churn-drill hole No. 4 has been started about 1000 ft. westerly from hole No. 3 in silicified, copper-stained schist, and is now down over 50 ft. Fisk & Snell, lessees of the Black Warrior mine, are employing 20 men on the 100, 250, and 300-ft. levels in cleaning out and repairing the workings, and getting ready for mining. E. M. White, manager for the Warrior Copper Co., has just returned to Globe from a business trip to Eastern cities. John Gibson, who is leasing on the Black Oxide vein at the Superior & Boston mine, corresponding to the Buckeye vein of the adjoining Buckeye mine of the Old Dominion company, has shipped to the Old Dominion smelter three cars of ore from stopes above the adit level, and is loading a fourth. The ore is estimated to average 7% copper. Frank Gill is employing two men in developing the Iron Mass & Pittsburg group of 18 claims, two miles north of Globe, adjoining the German Copper, Irene, and Old Dominion properties. A prospect shaft is being started on a vein on a limestone-diorite contact, having favorable indications of copper ore.

Globe, October 3.

#### GREENLEE COUNTY

The continued high price of copper and general mining activity throughout the country has given small mining companies in the Morenci district a new lease of life. The New York & Arizona Gold & Copper Co. has leased part of its holdings to Morenci men, who are working two shifts of miners breaking rich ore. The company expects to receive enough royalty to finance the purchase of a Nissen stamp-mill. The Home Copper Co. nearby is expected to start work soon. Several other properties are also about to resume operations.

#### PINAL COUNTY

Officials of the Ray Consolidated have been sampling the old Reymert mine, situated between Florence and Superior. The lodes in the upper workings carry lead and silver, while below the 400-ft. level rich copper ore was found 16 years ago by the old company.

### CALIFORNIA

#### KERN COUNTY

(Special Correspondence.)—The Gold Peak mine in Caliente canyon, with a 10-stamp mill and complete cyanide plant, has been bonded by Coulin brothers of Los Angeles and Bartlesville, Oklahoma. The mill is working full time. The Cowboy and Cowboy Annex claims have also been bonded by the same people, and the ore is being treated at the Gold Peak mill. S. G. Musser reports finding ore at the Krames Consolidated group, and rich ore is being shipped from the Musser lease. F. Krames is shipping

high-grade ore from the Manwell claim to the Amelia mill, which is being overhauled before handling the custom ore of the district, north of Paris. This district is more active at present than for several years, and numbers of prospectors are coming in from all parts. It extends from Gold Peak canyon to Piute mountains, a distance of 9 miles, and is 4 miles wide. Silver veins are large, and occur in the lime dike, which can be traced for 7 miles. Veins carrying gold are smaller but richer, and occur in pockets, similar to the Randsburg district.

Loraine, September 30.

#### SILASTA COUNTY

(Special Correspondence.)—With three furnaces in commission, the Mammoth Copper company is treating about 1275 tons of ore per day. About three-fourths of this is sulphide, and the rest fluxing material. The Mammoth ores average about 3% copper and \$1.50 to \$2 per ton in gold and silver. The zinc content is said to average 3 to 5%. The bag-house collects about 25 tons of fume per day, consisting largely of zinc oxide and sulphate. The Mountain Copper Co., Ltd., shipped 12,000 tons of ore to the Martinez smelter in September. Development is progressing

SUNSHINE MINE, HIGH GRADE DISTRICT.

at the Iron Mountain and Hornet mines, and the monthly pay-roll averages around \$25,000. It is reported that the ore reserves at the Iron Mountain are exceptionally satisfactory. This is the oldest copper mine on the Shasta belt, and has produced large quantities of high-grade ore. In the Pittsburg district, about 1½ miles north of Heroult, the Shasta-Belmont Mining Co. is developing a promising vein in the Graham property. Development consists of two adits and a 50-ft. shaft. The main adit is in 350 ft. At point of intersection the vein is 26 ft. wide. Assays average 4 to 5% copper, and \$3 to \$8 in gold and silver per ton. W. E. Casson is president and manager. It is planned to make the first test of the new copper-treatment plant at Heroult about October 19. The method is devised to smelt ores without generating noxious fume. Electricity is employed. The Clear Creek dredge, ten miles below Redding, is operating steadily. An excellent monthly profit is being earned, according to reports. The dredge is of the close-connected elevator type, equipped with 5-cu. ft. buckets. Oroville people, said to be representing Oroville Dredging, Ltd., are prospecting in the Clear Creek district with a Keystone drill. The ground has been worked in past years by ordinary placer methods.

Redding, October 7.

#### SIERRA COUNTY

(Special Correspondence.)—The 40-stamp mill has been started at the Alaska mine, near Pike City. The vein has been developed to a depth of 550 ft. and ranges from 2 to 30 ft. wide. The ore is low grade and free milling, and is crushed in rock-breakers and passed to the stamps, arranged in eight batteries. From the amalgamating plates the pulp flows to eight Wilfley tables, from which tailing passes to

settling-tanks, before being allowed to run to the restraining dam. Mine equipment includes two air-compressors, 25 machine-drills, and pumps having a rated capacity of 2500 gal. per minute. The Alaska is operated by the Sierra-Alaska Gold Mining Co. Charles Scribner, of the Scribner Publishing Co. of New York, and Gen. W. S. Schuyler, are prominent stockholders. George St. John is president and manager. Negotiations are pending for the transfer of the Squires gold quartz claim to San Francisco capitalists. The claim lies near Forest.

Downieville, October 5.

Work has been stopped at the Poker Flat mine on account of shortage of water. The shaft is down 550 ft. Gravel which returns a trifle over \$2 per load is being taken out at Deadwood. The owners of the gravel claim in Clark's canyon, at the head of North Fork, are preparing for winter and have built a reservoir to wash the gravel. Several men will start work at the Australia quartz claim in Slug canyon. Machinery at the Keystone has been repaired. From the face of the adit the lode shows free gold and sulphides, and there are over 1200 ft. of backs.

#### COLORADO

##### GILPIN COUNTY

The main shaft at the Manchester group of claims, on North Beaver creek, near Rollinsville, is down 115 ft. On the 100-ft. level the vein is 3 ft. wide, carrying a high percentage of tungsten. A 25-ton mill has been erected on the property and contains a crusher, rolls, and No. 6 Wilfley concentrating and slime tables. From an 8-hr. run last week, 600 lb. of concentrate worth \$125 was saved. Several more tables will be installed. H. and H. Eilman, leasing at the O. K. mine, on Central hill, have opened 6 ft. of ore at the 400-ft. level and are mining 200 tons per month. At the 100-ft. level of the Federal mine, in Russell district, the vein is about 3 ft. wide. A shipment of ore to the Iron City mill returned 1.56 oz. of gold, 59.65 oz. of silver, 3.35% copper, and 28.02% lead, and saved 90% of the metal content. Sixty-two tons of ore from the National adit, at Black Hawk, yielded one ton of concentrate worth \$78.79 per ton, and 16 tons worth \$15 per ton. This ore comes from a stope about 3500 ft. from the portal of the adit, and shows a width of four feet.

Development on the 100 and 200-ft. levels of the Buckley mine has opened a lode 36 in. wide, assaying 20 oz. of gold and 7 oz. of silver per ton. The shaft is down 630 ft., and the mine is equipped with plant to handle the present output. The Topeka is sending 65 tons per day to the mill at Black Hawk. The local pool working the Corydon mine has opened promising veins on the 200, 300, and 400-ft. levels.

##### JEFFERSON COUNTY

The North American Smelter & Mines Co., capitalized at \$2,500,000, and owning a smelter at Golden and mines in the Clear Creek-Gilpin district, is in the hands of a court receiver. Interest on bonds had not been paid, and holders of bonds worth \$500,000 had asked for the action. It is hoped to finance the company and resume operations. The smelter shut down last November.

##### LAKE COUNTY (LEADVILLE)

A large number of lessees in the district still have faith in Fryer hill, and after 33 years of strenuous work the famous hill continues to produce plenty of ore. Work is being done at the Chrysolite on the 210-ft. level; the Annie lessees are driving a raise to cut high-grade ore found in the upper level; shipments have been resumed from the Little Chief; the old McRae shaft is being unwatered; lessees at the Matchless are shipping from the 190-ft. level; and at the Duncan they are driving on the 200-ft. level. At the Brunswick, near the head of Big Evans gulch, work will be continued through the winter. Adits are being driven into the hill. This is a new district, and work will be watched with interest. The Sugar Loaf Consolidated is shipping 20 tons of ore per day.

## OURAY COUNTY

The Wanakah company is making a profit of \$10,000 per month, and is making improvements at the mine and mill. The Barstow is shipping a fair quantity of concentrate. The Butcher and Larsen lease, on the Jumbo, is looking well. A winze is 9 ft. below the drift, showing 12 in. of high-grade bismuth ore. Sundry work is being done at the Humboldt, Mineral Farm, Mono-Baltie, Congress, San Antonio, and Brooklyn properties.

During the past nine months of the current year, there has been shipped from Ouray mines a total of 13,588 tons of ore and concentrate, says the *Plaindealer*. The principal contributors to this total are the Wanakah with 4708 tons; Camp Bird, 4373 tons; Atlas, 1789 tons; Revenue, 699 tons; and Wedge, 555 tons. The power plants of the Revenue are at work repairing and erecting new lines having been done during this summer. Work is to be started at the Germania-Montfurst-Dykelot group of claims two miles east of Ouray in the Horseshoe.

## TELLER COUNTY (CRIPPLE CREEK)

According to local statistics, the September production of the Cripple Creek district totaled \$1,146,034, with a tonnage of 72,230. The local low-grade mills contributed about 29,000 to the total tonnage. The figures given out by representatives of the various plants are as follows:

	Tons.	Av. Val.	Gr. Val.
Smelters .....	3,885	\$15.00	\$250,275
Golden Cycle .....	29,500	20.00	590,000
Portland, Victor .....	14,700	3.06	44,982
Portland, Colorado City.....	10,000	22.00	220,000
Stratton's Independence .....	10,945	2.96	32,397
Cavanaugh .....	1,500	2.00	3,000
Isabella .....	500	2.00	1,000
Gaylord .....	1,200	3.65	4,380
	72,230	\$15.87	\$1,146,034

The flow of water from the Roosevelt tunnel is 9750 gal. per minute. The total drop in the water-level at the Gold Coin shaft of the Granite company has been 178 ft. Owing to the presence of gas in the Chickenhawk shaft on Guyot hill, a blower has been erected to remove it. During September the McKinney mine shipped 33 cars of ore worth \$35 per ton, while 12 cars came from lessees; the Granite production was 70 cars averaging \$25 per ton; from the Vindicator 68 cars worth \$68 per ton was mined from levels 14 and 15; and the Jerry Johnson sent out 17 cars, of which seven were from the chief lessee. In development at the 1600-ft. level of the Portland No. 2 shaft, one of the old orebodies has been opened. It is about 12 ft. wide, of fair grade. The mill is treating nearly 15,000 tons per month, one-third of which comes from the dumps.

A meeting of a number of those people heavily interested financially in the Roosevelt tunnel was held at Colorado Springs on October 4, and the question of another deep drainage bore was discussed. No definite estimates have been prepared; but it is stated that a tunnel 500 ft. lower than the Roosevelt would cost \$500,000. The latter cost approximately \$750,000. Another meeting will be held at an early date.

The *Colorado Springs Gazette*, in its 'Twenty Years Ago Today' column of October 4, said that at Cripple Creek the local mill was treating 50 tons per day, while 25 tons was being shipped. The stamp-mill was worked by G. M. Taylor, now manager of the Portland company's milling department. The shipments went out on burros. The present daily tonnage treated locally and shipped amounts to about 2400 tons.

## IDAHO

## COEUR D'ALENE

Fire broke out on October 7, in the Kellogg adit of the Bunker Hill & Sullivan mine; and fire crews, relieving each other at frequent intervals, tried to extinguish the outbreak. F. A. Benz, the pumpman, remained at his post until the fire short-circuited the current which drives the

pumps, and is now missing, though a rescue crew of four men, equipped with oxygen helmets, entered the workings on October 8. The fire broke out again late on the night of October 8 and was finally extinguished the next morning. The pumpman has not been found, and no hope of rescue is held out. About 600 men will be out of employment until repairs can be made.

## MISSOURI

## JASPER COUNTY

September was a month of record production, shipments, and prices for the Joplin district. Zinc ore prices averaged \$55.14, \$58.10, \$60.62, and \$61.10 per ton for each week respectively, the record price being \$64.50 for 60% ore during the third week. Calamine ore also profited by the advance, and averaged \$32 per ton for the month. The average weekly shipments were 6476 tons of blende, and 464 tons of calamine. Lead ore prices varied between \$59.75 and \$65.09 per ton, and 946 tons per week was shipped. The aggregate value of zinc and lead ores for the 39 weeks of 1912 is \$12,510,021, compared with \$9,719,480 for the same period in 1911. There has been a total of 194,895 short tons of blende produced during this period. Drills working at leases of the Gray land, southeast of Joplin, and on a lease between Thorns station and Carl Junction, have cut lead and zinc ore respectively.

## MONTANA

## SILVERBOW COUNTY

The September output of copper from the mines at Butte was 29,054,940 lb. The output from the various mines was as follows:

	Ore, tons.	Copper, lb.
Anaconda group .....	170,300	10,558,600
Boston & Montana group.....	108,920	7,079,800
Butte Coalition .....	37,260	2,645,460
North Butte .....	34,720	2,360,960
Butte & Boston .....	15,700	973,400
Alex-Scott .....	7,800	936,000
Trenton .....	15,110	921,000
Original .....	11,600	707,600
Washoe .....	9,210	561,810
Tuolumne .....	4,500	540,000

At the annual meeting of the Davis-Daly Copper Co., held last week, W. Bloom, of Boston, was elected a director to succeed F. A. Heinze. For the year ended June 30 the gross revenue was \$113,333, while total expenses were \$199,029, leaving a deficit of \$85,696. About 50 tons of ore averaging 4% copper and 6 to 8 oz. of silver has been shipped daily. The August revenue was nearly \$14,000. Extensive development has been the cause of much extra expenditure. The company was one of the first to recognize the miners' demand for increased wages, the present rate being \$4 per shift. The company's fixed assets are given as \$5,239,029; deferred, \$1,217,910; and current, \$214,244; making a total of \$6,671,184, almost similar to those of last year. Capital stock is \$6,000,000, current liabilities \$20,573, making the total liabilities \$6,020,513. The surplus account stands at \$650,671.

## NEVADA

## ESMERALDA COUNTY

(Special Correspondence.)—The estimated production of the Goldfield Consolidated company for September is \$390,000 from 29,460 tons treated. Operating expenses were \$190,000, leaving a net profit of \$200,000. The tonnage milled is low on account of repairs; while ore shipped was also low on account of repairs at the Grizzly Bear shaft.

Goldfield, October 2.

The storage battery at the Consolidated enabled the company to keep on working a great deal of its machinery, when the electric power was shut off last week, due to the plant of the power company being struck by lightning. The shaft at the Goldfield Merger mine, which is 7 by 18 ft.

in the clear, is being sunk to 2000-ft. depth. The Jumbo Extension is treating 60 tons of ore daily. At a point east of the shaft, and near the Merger mine, the company is mining 5 ft. of ore worth \$50 per ton.

The Pittsburg-Silver Peak company has declared a dividend of 2c. per share, which means the distribution of \$55,800. The mill is treating over 15,000 tons of ore per month. R. S. Peterson, a miner, has started a suit against the company for \$76,858.50 for injuries received when he and four others drilled into an old hole on June 15, 1911.

#### HUMBOLDT COUNTY

The National Mines Co. employs 60 men, and the Charleston Hill Syndicate 25 men. The former is mining high-grade ore from the undisputed part of the property, while the latter is working along the fault line. This work shows that the quartz stringers are all cut off by the fault, or penetrate no farther than the hanging wall. The contention is that all development by the Syndicate verifies the theory of A. C. Lawson as to the Charleston Hill faulting and the general movement. Work has progressed favorably, and by October 10 the Syndicate anticipates that it will discover the fault portion of the high-grade vein as foreshadowed by Mr. Lawson. The Wheeler Leasing Co. employs 10 men. The Wheeler adit has cut a number of veins carrying gold and silver.

#### MINERAL COUNTY

Another 50-ton mill is to be built at Rawhide, and a better feeling prevails in the district. The Nevada New Mines Co. has exposed two orebodies of \$25 average in the 365-ft. cross-cut from the Grutt Balloon, and 30 tons of ore is being added to the dump daily. Ore worth \$25 to \$40 per ton is being extracted from the Grutt Hill, Hooligan Hill, Marigold, Regent, Morning Star, and others.

#### STOREY COUNTY

The Yellow Jacket mill, at Gold Hill, is crushing an accumulation of Crown Point ore, which comes from the slopes on the 1400-ft. level. Shipments of ore have been sent to the smelters from the Gould & Curry and Comstock-Phoenix mines. The Mexican mill treated 422 tons averaging \$42.45 per ton, with 94% extraction. This ore came from the 2300, 2400, and 2500-ft. levels of the mine. At the 2500-ft. level of the Ophir, the southwest drift is out 576 ft. The Butters filter, and precipitating boxes have been erected in the mill. The usual work was done at the Consolidated Virginia, Union Consolidated, Sierra Nevada, and others on the Comstock. At the C. & C. shaft the pumps worked practically full time, while the shaft was repaired and other work done. All equipment and material has been taken from 2000-ft. level of Ward shaft, and the No. 3 pump at the 2100-ft. station is being dismantled.

Four mills in Sixmile canyon have a total of 40 stamps working on ore from the Lady Bryan, Comstock-Phoenix, East Comstock, Chollar & Potosi, and Monte Cristo mines.

#### WHITE PINE COUNTY

With the closing of the mill and smelter at McGill, the strike will affect nearly 4000 men, who were earning about \$300,000 per month. From indications it would seem probable that the Nevada Consolidated will not reopen the mines this winter. The manager of the Giroux Consolidated asked that the pump-men be allowed to work, as the mine will fill with water; but the request was refused. Everything is quiet and the best of feeling exists between the operators and men. The stock of ore on hand at McGill will soon be exhausted, and the mill will have to be shut down, followed by the smelting plant. It is said that the Kimberly concentrating plant of the Giroux company is to be overhauled and its capacity increased from 500 to 1000 tons per day. The company would have then to supply 1000 tons per day for the Steptoe plant under the 5-year contract, and a similar quantity for the Kimberly mill. On the 1000 and 1200-ft. levels of the Alpha, a large quantity of high-grade copper ore is ready for stoping. The Railroad Valley company has purchased a standard drilling rig and will soon resume drilling work.

## NEW MEXICO

### GRANT COUNTY

Five steam-shovels are working at Chino, ore coming from the Hearst-Carrasco and Chino sections. The fifth unit of the mill is about finished, and the September output should be about 4,000,000 lb. of copper.

## TENNESSEE

### POLK COUNTY

It is reported that the Tennessee Copper Co. will organize a new company with a capital of \$25,000,000, divided into 500,000 shares of \$50 each. The present capital is \$5,000,000, with 200,000 shares of \$25. The object of this is to provide funds for a new blast-furnace plant to treat the large quantity of iron sulphide ore developed. This will cost about \$2,000,000. After extracting sulphur and copper, the slag will be sold to cement manufacturing people, as it contains no phosphorus. An annual profit of \$1,000,000 is expected from the work.

## UTAH

### BEAVER COUNTY

The Moscow Mining company, in the North Star district, is shipping 15 cars of ore per month. A lode 5 ft. wide has been opened at the 500-ft. level, but has a low content in lead, silver, and gold. The Moscow vein has been cut by the drift which was driven from the shaft on the 500-ft.

UTAH-APEX MINE.

level to connect with the north workings. The drift has been driven 50 ft. on the vein, which is of good width and metal content.

### JUAB COUNTY

The mines of the Tintic district shipped 208 carloads of ore for the week ended October 4. The Mammoth company has declared a dividend of 15c. per share, equal to \$60,000, the first payment for nearly four years; and makes a total of \$2,280,000. The new orebody opened at the 600, 700, and 800-ft. levels has helped largely to bring about larger production. Eighty tons of silver ore, valued at about \$12,000, left No. 3 workings of the Iron Blossom last week. As much of this ore as possible will be saved for the new mill. Settlements for zinc ore from the May Day average \$20 per ton. Notices have been posted in the district announcing an increase of 25c. per day for all underground workers, at most of the mines. The Tintic District Miners' Union has appointed a committee to confer with the mine-owners.

### SALT LAKE COUNTY

The firm of Kirk & Leavell started to open the old workings at the New York, Minnie, and other claims of the Utah-Apex company on February 1 of this year, and found the old stopes, drifts, and raises badly caved, and treacherous to work in. Their lease expired on September 30, and during that time they employed from 30 to 135 men, and mined ore worth \$135,000, paying the company a good

royalty, and also doing fairly well for themselves and sublessees. The ore carries lead, silver, gold, and copper, with a small quantity of zinc occasionally, and averaged about \$25 per ton.

It has been announced by D. C. Jackling that the Utah Copper and Nevada Consolidated companies will pursue a waiting policy and that, though the companies are perfectly willing to treat with their men as individuals, they will not recognize the Western Federation. At Bingham it is hoped that the Utah Copper will soon be in a position to resume work.

## WASHINGTON

### FERRY COUNTY

G. E. Thornton, who has been prospecting for 10 years in and about the California mine, 9 miles southeast of Republic, has inherited one-fifth of an estate valued at \$125,000. The rearranged crushing department of the North Washington Power & Reduction Co.'s plant has doubled its capacity, making 125 to 160 tons handled per day. The ore now passes a Blake crusher to a set of 19-ton rolls, then to a revolving screen, from which the oversize goes through finishing rolls to storage bins. During the year ended May 31 the Republic Mines Corporation shipped 20,646 tons of ore valued at \$382,118. Mining, treatment, freight, etc., cost \$339,381, which left a surplus of \$42,737. The extraction was 66.2 per cent.

Spokane, September 20.

The Superior copper mine, near Browns Lake, in the west Chewelah district, has been leased for three years. Over \$25,000 has been spent in development of a lode 9 ft. wide, carrying high-grade copper-silver ore.

### JEFFERSON COUNTY

A company which intends to manufacture potash from kelp, a seaweed which grows prolifically along the Pacific coast, has located beds extending from Point Wilson to Middle Point, and also lying west of Smith island, in the Strait of Fuca.

## CANADA

### COBALT

The Cobalt Lake company has sent out a trial sample of ore assaying about 25 oz. of silver and 25% nickel. Four claims at the Gillies Limit have been sold for \$5000. They are situated close to the Waldman; and there is a large calcite lode from A99 to the upper claim of the group. A 3-in. vein of high-grade ore was cut on the 150-ft. level of the Crown Reserve last week, in a cross-cut, a distance of 800 ft. from the shaft. On October 1 the largest shipment of bullion that ever left Cobalt in one day was sent to Montreal, to be transhipped to England. There were 143 bars of bullion, weighing 159,400 oz., worth \$102,100, which came from the Nipissing, O'Brien, and Crown Reserve mines.

### PORCUPINE

At the Pearl Lake mine an orebody 18 ft. wide has been cut on the 400-ft. level, 224 ft. from the shaft at the south. It consists of veins of quartz up to 36 in. wide, in heavily mineralized schist, showing free gold. Assays return \$30 per ton. Driving is being pushed east and west and the shaft is being sunk to 600-ft. depth. A 20-stamp mill will be erected as soon as possible. Treatment at the Vipond mill is said to be good, with an extraction of 90%, at a cost of about 60c. per ton. At a meeting of the miners' union held last week, the general feeling seemed to be in favor of asking for the wage scale adopted for Porcupine in August 1911, and amended in October of that year. This wage is about 50c. per day higher than the present scale. The Board of Conciliation met at Toronto, and upon its decision depends whether there will be trouble between the men and mine-owners.

### YUKON

Construction of roads in the territory, under appropriations made at the recent session of the Yukon Council, is progressing so well that most of the work is about com-

pleted. The winter road to Glacier creek will be built before snow falls, and will follow up the Swede Creek valley, thus avoiding the high and dangerous Glacier ridge road in winter.

## MEXICO

### JALISCO

The Amparo mine, in the Etzatlan district of this state, is producing bullion worth ₧140,000 per month. Last year operations were interfered with by interruptions to the power service of the Chapala Hydro-Electric & Irrigation Co., but these have been few and short during the present rainy season. In November 1911 the shrinkage system of stoping was started, and by August of the current year there were 54,000 tons of broken ore in the stopes. The mill is now treating 260 tons per day. A 200-hp. Ingersoll-Rand compressor has been erected at No. 2 shaft, which is down 1120 ft. About nine cars of ore per month are being sent to smelters from El Favor mine, of the Makeever interests, in the Hostotipaquillo district. Development is mainly being done at the Mololoa mine belonging to the same people. The Espada Mines Co. is treating 100 tons per day at the Virginia & Mexico mill. So far this year concentrate and bullion worth ₧100,000 has been produced. The Miravalles Mining Co. has been organized to work the famous *antiguas* known as the Huicicila mines at Tepic, five hours from Composteba. They were taken over in July by W. R. Ramsdell, well known in this state, and are being opened under the direction of W. J. McCormick, formerly at the Casados and El Favor mines.

### MEXICO

(Special Correspondence.)—Water troubles have been overcome at the mine of the San Vidal y Anexas Co. at El Oro. While work on this was being done, a cross-cut was put in the hanging wall country to look for the vein which is opened in the shaft at a higher level. At a distance of 13 ft. west, a sulphide vein was cut, dipping northwest and approximately parallel with the San Carlos vein. It is about 33 ft. wide, and was cut a few feet below its apex. Samples from a well mineralized stringer on the foot-wall of the vein assayed 10 to 55 oz. of silver per ton. Shaft sinking is in progress.

El Oro, September 15.

### SONORA

(Special Correspondence.)—El Tigre was attacked by 350 rebels, under the leadership of Inez Salazar, on September 13. The camp was defended by 20 federal soldiers and 50 citizens. Reinforcements of 360 federals were despatched to the trouble, but failed to arrive. At 11 o'clock on September 14, the defenders retired and allowed the rebels to take possession, having exhausted all ammunition after 30 hours' fighting and no relief in sight. On September 16 the rebels left El Tigre, taking 21 bars of bullion worth \$25,000, which has since been recovered. Loss of merchandise, and one burned building, cost the company \$15,000. Railroad and wagon traffic has been resumed, and most of the rebels have left the district, which is occupied by federals. During September the plants were shut down for three days. On September 28, bullion valued at \$60,000 was received at Douglas, Arizona, and on September 30 bullion worth \$25,000 will be shipped from the mine. The accumulated production of ore and concentrate will be shipped as fast as possible.

Kansas City, Missouri, September 30.

### SONORA

As soon as the present unsettled conditions are over, a stamp-mill or concentrator of some type will be erected at the Golden Cross mine, in the Magdalena district. This property has ore carrying gold and silver, and is owned by the Dolores Mining & Development Co. of Oakland, California. The Major Domo claim, five miles from Cananea, will have its shaft sunk to 200-ft. depth, and the 100-ft. level driven in two directions. The Gordo mine, next to the Golden Cross, owned by Cananea men, is showing high-grade ore in one of the adits.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. H. BENJAMIN has gone East.

C. R. KEYES is in San Francisco.

PEREGRINE O. WILSON has gone to Mexico.

GELASIO CAETANI has returned from Arizona.

A. M. CHAMBERLIN has gone to Juneau, Alaska.

EDMUND JUESSEN has returned to San Francisco.

D. H. DUNN was in San Francisco during the week.

D. M. FOLSOM was in San Francisco last Thursday.

ARTHUR A. FRANCIS has gone to Spain for a brief stay.

R. S. BOTSFORD is now at Bogoslovsk, in the province of Perm, Russia.

ALBERT WHITE, of San Francisco, has gone to Auckland, New Zealand.

LIONEL LINDSAY has returned from a trip to the South-western states.

H. HENDRICKSON is now with the Cia. Minera de Penoles, Ojuela, Durango.

BRANTON BIGELOW has returned to Goldfield, Nevada, from Treadwell, Alaska.

A. J. FISHER, of San Francisco, has gone to the Black Oak mine, Soulsbyville, California.

B. N. LEHMAN has returned to Salt Lake City from a visit to the Yankee Consolidated mine.

E. F. BURCHARD is returning from Juneau and expects to reach San Francisco on October 22.

MARSHALL S. WALKER has accepted a position in the United States Assay Office, New York.

A. G. CHARLETON has left London for the Continent, expecting to return from Sicily about November 8.

FOREST B. CALDWELL, superintendent of the Candelaria Consolidated Mexican Mining Co., is in San Francisco.

FRANCIS P. BRAY, general manager for the West African Trust, Ltd., has left the Gold Coast on his annual holiday.

A. ADIASSEWICH has returned from the Caucasus and has left London for a five months trip to the United States.

F. H. MORLEY will sail at the end of October for an extended holiday trip in Egypt, Greece, and southern France.

RUSH T. SILL and HARLEY A. SILL have opened offices at Los Angeles as consulting mining and metallurgical engineers.

WILLIAM T. CARDWELL has left Cananea, Sonora, Mexico, where he has been with the Puertecitas mine, and is now at Miami, Arizona.

H. FOSTER BAIN was in New York, Washington, and Pittsburg during the week, and has gone to Chicago, expecting to return to Cleveland on October 27.

TADASHIRO INOUE, professor of mining in Tokyo Imperial University, was in San Francisco during the week and has gone to the dredging fields and the hydraulic workings in Trinity county.

FREDERICK G. CLAPP spent a part of September and October in Ontario and Quebec in connection with a general investigation of the oil and gasfields of Canada which the Bureau of Associated Geological Engineers is making for the Canadian Department of Mines.

## Obituary

HENRY E. PICKET died at Berkeley, California, September 27, at the age of 74. A native of Pennsylvania, he went to the Black Hills in the first gold rush, and later moved to Placerville, California, where he was engaged in mining for many years. The later years of his life were occupied in real estate ventures in Sacramento.

STORAGE OF WATER FOR IRRIGATION PURPOSES. Part I. Earth-Fill Dams and Hydraulic-Fill Dams. 95 pp., 20 pl., 41 fig. Bull. 249. Part II. Timber Dams and Rock-Fill Dams. 64 pp., 8 pl., 38 fig. Bull. 249, U. S. Geol. Surv. Washington, D. C., 1912.

PRODUCTION OF MINERAL WATERS IN 1911. By G. C. Matson. With, CONCENTRATION OF MINERAL WATER IN RELATION TO THERAPEUTIC ACTIVITY. By R. B. Dole. Advance chapter from 'Mineral Resources of the United States, 1911.' 60 pp. Washington, 1912.

CHART OF THE ELEMENTS. Published by the Metallic Compositions Co. 43 pp., ill., tables. London, 1912. This publication consists of a large chart based on the periodic law of the elements according to Mendeleeff. Principal properties are given of each element in abstract together with explanations of the chart.

RECORDS OF THE LONDON AND WEST COUNTY CHAMBER OF MINES. 8 pp., tables. London, July 1912. Of late practically the only function of this institution has been to collect and publish statistical and reliable information relating to the mines of the west of England, which is not the purpose of a chamber of mines. Many useful subjects could be discussed, but proper meetings could not be arranged. The Chamber therefore is dissolving. There has been a quiet revival of interest in Cornish mining; and now is the time to move if anything is to be done toward the formation of a really useful chamber of mines.

THE Ruby gold-placer district of Alaska, on the south side of the Yukon about 175 miles below the town of Tanana, is discussed in Bulletin 520-J of the U. S. Geological Survey by A. G. Maddren. Late in the summer of 1907 a report was circulated along the Yukon that prospects of placer gold had been discovered on Ruby creek, and the district has since received some attention from gold-seekers. The discovery was made at the mouth of the creek in some fine gravel at the level of the spring high-water mark of the Yukon, of which the creek is a tributary. During the summer of 1911 the report of new discoveries attracted a large number of persons to this district, but the actual discoveries of placer gold up to the time of the latest reports do not seem to indicate that this will be a new bonanza field, although many are of the opinion that they indicate more extensive deposits of gold-bearing gravels.

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

**S**CALE in boilers one-sixteenth of an inch thick means a loss of 25% in efficiency.

**E**NERGY in coal that is being effectively utilized is probably not over 11 per cent.

**E**LECTRIC incandescent lamps were invented by T. A. Edison, 30 years ago, on September 4, 1882.

**Z**INC has been, and in general still is, considered about the worst impurity to be found in copper and lead ores, as it has always given trouble in their treatment.

**B**ITUMINOUS coal amounting to 406,000,000 tons was produced in the United States last year, yet only \$3,800,000 worth of nitrogen was recovered out of \$160,000,000 worth that could be recovered.

**E**LECTRIC power is to be transmitted 80 miles to the city of Tokyo, in Japan. The scheme involves building a high-pressure power line, and 60,000 hp. will be developed from the rapids of the Kinu river.

**S**ULPHURIC acid amounting to about 3,000,000 tons is produced yearly in the United States, of which nearly one-half is used in manufacturing fertilizers. Smelters discharge enough SO<sub>2</sub> into the air to make over 8,000,000 tons of this acid.

**S**CIENTIFIC control of combustion under boilers is increasing, but the losses of carbon which still pours from chimneys, defacing monuments, buildings, and landscape, are without valid reason. It is one of the evils of modern civilization.

**N**ITROGEN amounting to 810,000,000 tons has been wasted in the United States since 1893 through the use of the old-fashioned beehive coking oven. By-product coke-ovens would have yielded from this coal 9,315,000 tons of ammonium sulphate, worth \$60 per ton, which could have been used as a fertilizer instead of importing \$15,000,000 worth of potash from Germany every year.

**P**ENNSYLVANIA has yielded 2,270,798,737 short tons of anthracite and 2,396,491,260 tons of bituminous coal since 1814, the date of the earliest record of coal production in this country, according to a chart just issued by the United States Geological Survey. Illinois comes second with 844,012,353 tons of bituminous; West Virginia third with 649,448,201 tons; and Ohio fourth with 611,949,292 short tons. These four states have therefore produced 6,772,699,843 tons in 98 years; or more than three-quarters of the total output of the United States.

**P**LATINUM is usually found as small nuggets, scales, and rounded or irregular grains. The specific gravity of crude platinum varies from 14 to 19, and percentage of metal contained is 70 to 85%. The output from the United States is almost wholly from California and Oregon. Owing to its high melting point and resistance to acids, platinum is used for laboratory apparatus; in making kettles for concentration of sulphuric acid; in photography, dentistry, electric installations, jewelry, and electric lamps. Its use for jewelry is unfortunate, as other metals can be substituted. Tungsten is replacing platinum in incandescent lamps; and an alloy of nickel and chromium is used for triangles used in laboratories. Platinum salts are used in chemical analysis.

## Commercial Paragraphs

The BRADEN COPPER Co., of South America, has just placed an order for four 8-ft. diameter Hardinge pebble-mills, all-steel trunnions with cut gears, for concentration grinding. These mills are similar in type to those furnished to the Miami and other copper companies of Arizona.

An arrangement has just been consummated whereby the Mexico Mine & Smelter Supply Co., will have the exclusive agency in Mexico and Central America for the OLIVER CONTINUOUS FILTER Co. N. Guthridge, Ltd., of Sydney and Melbourne are the Australian agents for the OLIVER CONTINUOUS FILTER COMPANY.

LEROY A. KLING, who has been connected for some time past with two well known crusher companies in Cedar Rapids, Iowa, has accepted a position with the WHEELING MOLD & FOUNDRY Co., of Wheeling, West Virginia, as sales manager of the road machinery department. This is the concern that has built considerable machinery for the Panama canal. It will eventually manufacture a complete line of road-building machinery, including a modern crusher, adjustable to crush to any size, pulverizers, rolls, screens, elevators, trucks, and graders.

J. W. STONEHOUSE, Victor, Colorado, is placing on the market enameled steel signal signs for mines. Their advantages are obvious, as they are not affected by moisture, are always legible, and much more durable than cloth signs. Among the mines equipped are the following: Copper Queen Con. Mining Co., Bisbee; Calumet-Arizona Mining Co., Warren; Shattuck-Arizona Copper Co., Bisbee; United Verde Copper Co., Jerome; Old Dominion Copper Co., Globe; The Arizona Copper Co., Ltd., Clifton; Arkansas & Arizona Copper Co., Jerome; Ray Con. Copper Co., Ray; Mascot Copper Co., Dos Cabezas; The Detroit Copper Mining Co., Morenci; Great Western Copper Co., Courtland; Commonwealth M. & M. Co., Pearce, in Arizona; and in Colorado, Stratton's Independence, Ltd., Victor; Vindicator Con. Gold Mining Co., Independence; Isabella Mines Co., Cripple Creek; The Ajax Gold Mining Co., Victor; The El Paso Con. Gold Mining Co., Victor; Gold Dollar mine, Victor; and Golden Cycle mine, Victor.

An evidence of the increasing attention being given to the most efficient methods of advertising and marketing engineering and technical products appears in the announcement of the formation of the firm of WIGHTMAN & RICHARDS, technical department of Jos. A. Richards & Staff, general advertising agents, Tribune building, New York City. Associated in business are Joseph A. Richards, Lucius I. Wightman, and Paul Morse Richards. Mr. Joseph A. Richards is the head of the agency having his name, founded by Joseph H. Richards in 1872, and since identified with some of the most conspicuous national successes in advertising salesmanship. Mr. Wightman is an engineer who has for many years specialized in the advertising and marketing of machinery and engineering products, and brings to the association several important technical accounts. Mr. Paul Morse Richards is a publisher, sales manager, and advertising man of wide experience, until recently with *Motor World*, and prior to that, advertising manager for *Power* and other technical journals. His extended experience will aid in the conduct of advertising, selling, and marketing campaigns. Wightman & Richards bring to the field served by the technical press that much needed combination of agency facilities with specialized technical and engineering skill. The scope of their services covers every proved method of legitimate sales increasing and business building, direction and preparation of advertising and advertising literature, mailing lists, sales campaigns, marketing plans, and the organizing and systematizing of advertising departments.

URUGUAY's only producing gold mine in 1911 yielded bullion worth \$68,321 from 20,489 long tons of ore treated, according to a consular report.

## EDITORIAL

**F**ORMATION of a mine-owners association for Utah is proposed and is eliciting the support of prominent operators.

**N**EARLY 25,000 employees of the United States Steel Corporation are shareholders, their holdings aggregating 103,000 shares.

**C**ONFERENCES on mine rescue and first-aid work were held in the Bureau of Mines building, Pittsburg, last month and agreement was reached on methods to be followed in this important work. The committees made a number of useful suggestions, both for coal mine and metal mine operations, some of which we shall publish later.

**A**USTRALIANS rejoiced at the turning of the first sod in the construction of the Port Augusta-Kalgoorlie railroad on September 14. The road is to be 1060 miles in length and will link the eastern and western coasts of that commonwealth. A graceful compliment was the grouping of the flags of Great Britain, Australia, and the United States. Australian problems have many points in common with those which have developed here, and the exchange of citizens between the two countries, largely as a result of mining activities, has been helpful to both. It is gratifying to know that Australians reciprocate in full the friendly regard in which they are held by Americans.

**D**ECISION of the Attorney-General of Colorado that the bequest establishing the Myron Stratton home has not lapsed, even though in the nine years which have elapsed since the death of W. S. Stratton the provisions of his will concerning the sale of his real and personal property and the establishing of the home have not been carried into effect is reassuring and commendable. Execution of the provisions of the will has been delayed by interminable litigation, the claims brought against the \$6,000,000 estate aggregating over \$23,000,000. Provision of a home for the aged poor is a worthy charity, and it is to be hoped that the trustees, Messrs. D. H. Rice, T. S. Dines, and William Lennox, may soon be able to carry it into effect.

**P**ROPOSED changes in the constitution and by-laws of the American Institute of Mining Engineers are given at some length elsewhere in this issue, and we would urge their careful perusal by all the members. The proposed changes outline a constructive program for the enlargement of Institute activities upon a business-like basis. A committee is at work to devise the best plan for coördinating the work of the Board of Directors and the Council, and its proposals, together with other suggested changes, will be communicated to the membership in time to allow full discussion before final action at the annual meeting in February next. Among the most important changes it will be noted that the Board of Directors, who are legally responsible for the conduct of the Institute, will assume active supervision of its financial affairs, leaving the tech-

nical activities, as heretofore, in the hands of the Council. Each of these bodies is to have a secretary, and the business activities of the Institute are to be under the direct supervision of a business manager. Editing of the Institute publications is to be performed by an editor, under the control of a committee on publications. The success of such an arrangement is likely to depend upon the personnel of the committee, and a statement as to the results of the arrangement in force during the past year would be of service. We hope the proposed changes will be fully discussed by the members, and we offer the freedom of our 'Discussion' columns to the membership.

**K**AMLOOPS recently celebrated its centenary, and the event was signalized by a gathering of the Fraser river pioneers in gold mining. What is known of the early history of British Columbia has, through the courtesy of Sir Richard McBride, Minister of Mines, been gathered into a pamphlet, 'The Days of Old and Days of Gold.' Not the least interesting of the material are the quotations from 'Sawney's Letters' by James Anderson. This stanza indicates that life in the early days sometimes brought more of hardship than wealth.

"Dear Sawney.—Little did I think  
That Eighteen Sixty-seven  
Wad see me still in Cariboo,  
A howkin' for a livin'.  
The first twa years I spent oot here  
Was nae sae ill ava,  
But hoo I've lived since syne, my freen',  
There's little need to blaw!  
Like foot-ba' knockit back an' fore,  
That's lang in reachin' goal,  
Or feather blawn by ilka wind  
That whistles 'tween each pole;  
E'en sae my mining life has been  
Fu' mony a weary day,  
(Will that sun never rise for me,  
That shines for makin' hay?)"

**C**ONDITIONS in Mexico have temporarily improved. The Chihuahua *Enterprise* has resumed publication after a suspension of four months, due to the political situation, and the mining companies in northern Sonora are again at work. The El Tigre mine, which produced only one-third of its usual output during September, expects to make a normal profit this month, while other mining and smelting companies are in as steady operation as circumstances will permit. An engineer who has recently returned from Sonora is of the opinion that permanently settled conditions cannot be expected without the intervention of the United States authorities. Brigandage is alluring to the primitive element in all human character and, by a gradual transition from what was denominated patriotism at the outset, has now attained the freedom from disrepute which is the natural result of common public practice. The bands are swayed by local considerations rather than patriotic policy and the body politic has become so thoroughly disorganized that only vigorous measures can restore order. The present government could restore order by the adoption of the vigorous policy once practised in Mexico, but the world's public opinion will no longer countenance such methods. By educating the Mexican people to the necessary standards of self-government a lasting and better result will be obtained, but the process is necessarily slow and a degree of order is a prerequisite, just as a teacher must maintain order in a school-room if effective work in educating the pupils is to be performed. It is evident that no one desires to even appear to interfere with the liberty of the Mexican people to conduct their affairs in their own way; the conduct of other nations

during the past year is irrefragable evidence of this. But liberty and license are different things; those who wish to enjoy liberty must refrain from license. It is gradually becoming evident that just as our freeing of Cuba from Spanish oppression has entailed our supervision of the Cuban form of government to prevent the recurrence of conditions no less deplorable, even though brought about by the Cuban people themselves, so the position taken by the United States to prevent the interference of European nations in Mexican affairs entails a corresponding obligation to prevent the maintenance in that republic of conditions which would reasonably require the interference of outside powers. We have been patient with Mexico, but there comes an end to all patience.

### The Fruits of Violence

The attempted assassination of Mr. Theodore Roosevelt at Milwaukee on Monday failed of its object, and with characteristic vigor our virile ex-president continued his way to the convention hall and delivered his address as expected, though bleeding from a bullet wound in his chest. The motive for the deed has not been disclosed at the time of writing, but it is generally accepted that the violent abuse that is characteristic of comment upon men in public life is at least indirectly responsible for a deed so contrary to the whole spirit of our American institutions. Criticism of this phase of current politics is more merited because the practice has become so general, the men of Mr. Roosevelt's own party being as culpable as his opponents. Politicians and newspapers seem to find it difficult to believe in the intelligence of the American voter, and think by a flood of abuse of opponents to attract adherents to their own political propaganda. Yet political events of recent years have all gone to show that the general public in this country is reasonably well informed and can only be effectively reached by arguments which appeal to its intelligence. The use of billingsgate as a campaign argument is not new, for it is proportionately less used now than in former years, but it has become more prominent with the growing tendency to conduct political campaigns through the use of newspaper columns rather than from the stump. It is to be hoped that an aroused public sentiment may bring to an end, once and for all, the use of such methods. For the benefit of our subscribers in the lone places, let us add that, in our opinion, the attempt upon Mr. Roosevelt's life makes his election in November highly probable, where it was previously doubtful. There is an element of boyishness in American character, and a man who, with a bullet in his chest, delivered an address on the necessity of being a good soldier, is likely to thereby win votes that would be unaffected by logical arguments. The great strength of the Progressive party largely lies in its labor policy. Nearly two-thirds of the people of the United States are engaged in gainful occupations, and the constructive and intelligent scheme of labor legislation of the Progressive party, backed by a general belief that Mr. Roosevelt is the only candidate who is virile enough to be able to put his pre-election promises into effect, is likely to prove a powerful factor in the election. New York has more electoral votes than all the states west of the Rocky Mountains and will exert a corresponding influence in the election. Mr. Oscar Straus has been nominated by the Progressives for governor of that state, and the weakness of his opponents, together with his high personal repute, makes his election almost certain. Whether he will be able to carry the state for the national Progressive ticket is a question, the answer to which will largely determine the outcome of the election next month.

### Ideals of Imperfection

The passing of the vanning-shovel assay for tin, chronicled in our London letter this week, is an unlamented departure. Another metallurgical ideal of imperfection has gone to take its rightful place in the limbo of oblivion, together with the fire-assay for copper and for lead. The persistence of outgrown structures and methods is a characteristic of the animate world. The rudimentary vestiges of his ancestral five toes sometimes interfere with the locomotion of the horse, and the vermiform appendix, the shrunken remnant of a once useful structure, is a constant menace to the health of men. Similarly, the crude methods devised to meet the conditions of pioneer work often persist to hamper progress in later development of industry. Correct judgment of the relativity of conditioning circumstances is one of the most valuable as well as one of the less common human attributes. Where the conditions are simple their relations are easily perceived. Anyone would merely estimate that a nearby town is two or three miles distant in deciding whether to walk or hire a carriage; or would measure it carefully before letting a contract for paving the road; or would measure the distance with extreme refinement of method if it is desired to use it as a base-line in carrying out a survey. It is not so generally recognized that the choice of method to best serve the desired end also involves a corresponding definiteness of the concept of what is required. In the first case, the one who makes the estimate probably will not stop to consider whether the estimated distance is to the edge of the town or to its centre, but in drawing contract specifications for the paving work it will be carefully provided that the pavement shall begin at a certain street corner and end at another specified one, while before beginning the base-line measurement much care and effort will be necessary to establish permanent monuments upon which the exact point of origin may be marked with the greatest precision. In chemical work similar relations are even less evident. It is not only the beginner in quantitative analysis who slights the work of solution, precipitation, and filtration in a vague hope of securing accurate results by careful measurement at the end, while it is only of recent years that the relation between the method and care employed in the taking of samples and the trustworthiness of the final analysis has been generally recognized.

In the complexity of modern life economy of effort, the conservation of mental energy, is a prime consideration. Curiously enough, it is found that primitive methods, generally devised to secure the desired result with a minimum of immediate effort, do not conduce to this end, because of their absence of definiteness. Exact classification and comparison is impossible when the things to be classified and compared are themselves devoid of exactness, and endless confusion is the result unless an appalling amount of mental energy can be devoted to the consideration of single items. The use of crude methods is, therefore, the reverse of expeditious, and effectually hampers the development of exact knowledge which is the prerequisite of useful progress. The vanning-shovel assay of tin obscured the fact that the recovery of that metal by the mechanical methods employed is so imperfect as to call for careful study and to offer wide scope for improvement. Similarly the fire assay for lead ores served to obscure the defects of crude metallurgical methods when it was first employed, though in this case its abandonment followed as a result of improvement in metallurgical methods, rather than as a means to that end. The first consideration in deciding whether present methods are adequate is to find out exactly where we stand and to clearly understand what it is we wish to do. Precise methods need not be employed for rough determina-

tions, but the relation between the method employed and the results derived should be clearly understood. Present-day problems are problems of refinement of method. Products once wasted must be saved. In carrying out his own activities each must observe the rights of others. Right decisions depend upon exact knowledge; whether a smelter is a public nuisance or a public benefit is not a matter to be settled by public clamor, but by exact determination. Whether large corporations are necessary and useful factors in the conduct of business, or whether they are potent forces oppressing the public is not to be decided by the utterances of speakers or journals owned by large corporations or by revolutionary societies. Whether it is possible to secure larger compensation for labor and immunity from the perils of work without unduly burdening industry, whether prompter justice cannot be obtained without incurring danger of injustice, whether the right road of progress lies to this hand or that is not to be disclosed by vague discussion, loose methods of thought, inexact concepts, and crude methods of analysis. Ideals of imperfection lead only to stagnation, perfection of result is attained only through approximation to ideals of perfection.

### Antimony Production

The smelting of antimony at Tacoma is proposed as a result of the development of the Black Eagle mine in the Vault Creek district of Alaska. Antimony production has so far been almost monopolized by the gold mines of France and the antimony mines in Hunan province in China. The supply of the metal is ample for the demand it enjoys, and the development of antimony deposits in this country must needs depend upon local favorable conditions. The sale of the metal is under the control of an international syndicate and the individual producer can scarcely find production of antimony an inviting field for his enterprise. Much of the present demand for antimony in the United States is met by the production of hard, or antimonial, lead by the principal lead smelting companies, and the yearly imports of antimony only amount to about 5000 tons. Deposits of antimony ores are known to exist in Nevada, Arkansas, and other states, but none of them are now being operated, and the small smelting plant near San Francisco has also ceased work. The production of metallic antimony, or antimony regulus, as it is known to the trade, involves the employment of a considerable amount of hand labor, and the lower wage scale prevailing in France and China is an advantage not easily to be overcome. The treatment of other than high-grade ores is somewhat expensive, and in China the crude ore is carefully hand sorted before subjecting it to metallurgical operations. In France the antimony is associated with gold and is obtained as a by-product of gold recovery. La Lucette is the most notable mine, producing about one-half of the antimony output of France and about one-quarter of the world's production, though the Chinese output has been increasing more rapidly than that of France. The uses of the metal are numerous, its alloys, which are used for bearing-metal and type-metal, are universally known, and a variety of other alloys are used in a lesser degree. The use of antimony oxide is growing, especially as a cheaper substitute for tin oxide in ceramics and the manufacture of enamels. It is also used in the manufacture of white paint, where a mixture of metallic salts is found to give better service than the unmixed lead salts. The lead supply of the world is apparently a limited one, and the possibility of its exhaustion is often discussed, but the known antimony supply is ample to meet all present needs for the metal, and probably future ones as well, so that the field offers no great attraction to producers.

## An Electric Hoist With Automatic Control

By FRANK C. PERKINS

The accompanying illustration shows the construction involved in a new English method of operating electric hoisting engines at the Auchincruive colliery of William Baird & Co. At the Auchincruive pits the problem to be met involved the electrification of all the auxiliary machinery at three hoisting shafts and the complete electrical equipment of two new pits, situated  $1\frac{1}{4}$  miles distant. This scheme provides for the generation of electric power by the use of exhaust steam in mixed-pressure turbo-alternators at the three steam hoisting shafts, and its transmission to the two outlying pits for operating electric hoists upon the 'Thury' or 'series' system was adopted. It is thus possible to use a high-tension alternating-current plant for generating and transmitting the power, while at the same time the advantages of the Thury system were fully utilized at the coal-hoisting plant at the Auchincruive pits.

With this system there is an entire absence of rheostatic control, the hoist motor used having similar characteristics to a steam hoisting engine and its simplicity of operation. In this mine power-plant there are two 600-kw. Dick-Kerr mixed-pressure impulse turbines, running at 3000 r.p.m. direct connected to two 625 kva., 3-phase, 50-cycle, 3000-volt alternators, the voltage of the machines being controlled by voltage regulators of the Thury type. It may be stated that the turbines take the exhaust steam, when available, from hoisting and auxiliary engines in use at No. 1, 2, and 3 pits, and operate in conjunction with Korting jet condensers. The circulating water is re-cooled by being pumped through spray nozzles distributed over a cooling pond.

The current is used for operating the main ventilating fan, for haulage, screening and washing, and pumping, and this part of the installation calls for no special comment. The sub-station at the new pits contains the hoisting plant, together with the fly-wheel set and switchboards. The incoming transmission cables are connected to a five-panel board, the incoming panel being fitted with voltmeter, ammeter and oil switch, bus-bar switch, and recording wattmeters. The other panels are used for distribution only and are exact duplicates, except that no voltmeters or wattmeters are needed. It is of interest to note that the induction motor is provided with a Thury slip regulator, the object of which is to limit the current taken from the alternating-current power supply; this regulator controls a resistance in the rotor circuit, cutting it out automatically as the motor picks up its speed, until the full speed of 428 r.p.m. is obtained. If the load on the series generator becomes heavy, and the induction motor is in consequence overloaded, this slip regulator puts resistance into the rotor circuit, preventing a heavy rush of current from the powerhouse, and by allowing the set to slow down enables the fly-wheel to transmit its stored energy to the series generator when the demand caused by hoisting is heaviest.

There is in the sub-station a motor-generator fly-wheel set, consisting of a 250-hp., 2750-volt, 50-cycle, 3-phase induction motor direct coupled to a 10 ft. 6-in. fly-wheel, the rim of which weighs 4.7 tons. This is in turn coupled to a 450-kw., constant current, direct-current series generator, built and designed to give 450 amperes at a voltage varying from 0 to 1000, and suitable for running at a speed varying between 375 and 428 r.p.m. The current from this generator operates the two hoists, one at each end of the sub-station, and for this reason alone the system is worthy of the close attention of all interested in electric hoisting, as with the fly-wheel systems hitherto in use a fly-wheel set has usually been necessary for each individual hoist.

When the hoists work in rotation, it is found that one of the motors returns energy to the fly-wheel set during retardation, while the other motor takes current for accel-

eration, thus enabling the fly-wheel to run at a fairly constant speed. In case of failure of the current supply, the stored energy in the fly-wheel is capable of enabling the hoist to complete a trip. Each of the hoists is driven, through double-helical reduction gearing, made by the power-plant company and having a ratio of 8.4 to 1, by a 275-hp. constant-current series motor, absorbing 450 amperes at a voltage varying from 0 to 500.

It may be mentioned that the control levers rest in a vertical position corresponding to the neutral position of the brushes, and the movement of either lever moves the brushes in a corresponding direction, causing the motor to run either way, as the case may be. Supposing either lever be pushed forward and the motor run up to speed, then by merely pulling the same lever over past the central notch in the guide quadrant the motor is made to act as a generator, returning current to the system, and a powerful braking effect is applied to the drum, causing the hoist to stop in the required period of time. The drums are 10 ft. diameter and the usual mechanical brakes and safety devices are fitted. The speed of the motor is controlled by moving the brushes backward or forward from the neutral position, according to which direction of rotation is desired; if the brushes are kept in the neutral position, the motor remains at rest, even if the current is passing through it.

There are two methods of controlling these motors; one is purely mechanical, the brushes being moved backward or forward by a lever connected to them by a rod; the other is an electrical one, and in this case the hand lever is connected to a regulator operated by oil pressure, which in turn is connected to the brush gear. When the electrical control is in use the direct hand control cannot be used, as the oil pressure in the regulator, 100 lb. per square inch, is too powerful to allow of the brush-rocker being moved by hand; should, however, this oil pressure fail for any reason, the hand control is immediately available without the operator having to move from his usual position. It is pointed out that the usual foot-brake is used to a very limited extent, and in practice only during the last fraction of a second for the purpose of causing the drum to stop at the exact levels. The action of both levers is the same, only with the regulator control the lever simply moves a valve in the oil supply to the regulator in question, after which further movement of the brushes is automatic; therefore, the operator only has to control one lever and a foot-operated brake lever.

It may be of interest to note the difference in the action of the hand and automatic control, especially with an unbalanced load with hand control. Under these circumstances, if the cage is being lowered, the weight, of course, helps the motor, and after merely pushing the hand control lever half-way and releasing the foot brake, the drum picks up speed very quickly, and this lever has to be brought back into the reverse or braking position. With the automatic control in use the starting lever is simply pushed to the full speed position, irrespective of whether the load is balanced or unbalanced, or whether it is being raised or lowered. As soon as the drum is up to speed the regulator automatically keeps it at that speed, and when it is required to stop the cage the starting lever merely has to be brought back to the neutral position, when the regulator causes the brushes to come over to the full braking position until the drum stops. The entire absence of sparking on the brushes of either the motor or the generator at any period of a hoisting operation is most noticeable, and the system admits of the easy application of an overwinding device.

There is a depth indicator dial facing the operator, and at his side is a main switch and a voltmeter which indicates the load. This switch is the only one in the motor circuit,

and is used to short-circuit the line when it is desired to cut off the current of the hoist motor, equivalent to a main stop valve in steam hoisting practice. No rheostats or starting resistances are needed. The speed of the motor is controlled by the regulator when the electrical control is being used. Operating in conjunction with this regulator is a magneto, which is so connected that the stronger the magneto current the slower will be the speed of the motor. What is done, therefore, is to put a resistance on the back of the depth indicator dial, together with a pointer fixed on the indicator spindle. While the cage is between levels resistance is kept in the magneto circuit, thus allowing the hoist motor to obtain full speed. But when the cage is close to the top, this pointer cuts out the resistance, and the drum automatically slows down; the arrangement is thus exceedingly simple, and the resistance is adjustable, so that any required speed may be used.

It is said that under the new English Mines Act every

lever holding the weight for the emergency brake, which acts on a brake-ring fixed to the motor-shaft. The other end of the rod is joined through a suitable lever to the brush-rocker of the motor and regulator, the operation being simple. The levers underneath the revolving spindle are set so that when the cage is at the end of its travel the cam meets one of the levers and pushes it over, thus operating the trip-plate, applying the brake, bringing the brushes on the motor to the neutral position, and putting the regulator out of action. If the cage is traveling in the other direction, then the cam meets the other lever. The operation of re-setting the device is very simple.

The electric hoist has a drum 10 ft. diameter. The output for each shaft is 600 tons in 8 hours, and the depth of the shaft is approximately 80 fathoms, while the average coal hoisted per trip is one ton. The duration of hoisting is 33 seconds and the duration of stop 15 seconds, while the period of acceleration is 12 seconds, and the period of re-

ELECTRIC HOIST MOTOR AT AUCHINCRAIVE.

hoisting plant with a vertical shaft is required to have a device which will prevent overwinding. For this reason a tripping device has been arranged, by which means a powerful brake is applied to the drum as soon as the cage passes the predetermined level. This arrangement, as fitted, is composed of two distinct parts, one, purely electrical, designed to reduce the speed and momentum of the cage to within convenient limits before it reaches the surface level, while the other is a mechanical contrivance for applying a brake if the cage actually passes this level; thus both cages are protected by this system.

In this equipment there is a hollow spindle bolted on the end of the drum shaft, with grooves, opposite one another, along its length and connected with its interior; inside is a screw fixed at the end farthest away from the drum, so that the screw does not revolve with the drum. There is a circular cam on this spindle which can slide along its axis. On the interior screw is a nut with two side-pieces to it, which project through the grooves in the spindle, and fit in the cam. When the drum revolves the spindle moves the nut around on the fixed screw, and this cam is pushed in one direction or the other by the projecting pieces of the nut. Exactly underneath the spindle, and parallel to it, is a steel rod on which two levers are keyed, at a distance capable of adjustment. To one end of the rod is connected a trip-plate, on which rests the

tardation 4 seconds. There are several distinct advantages claimed for this hoisting system in comparison with other electrical systems in addition to those already noted. A motor generator set is not required for each hoist, and several hoists can be operated by one set. If the central station is situated at a suitable point, several hoists can be operated in series. As more pits are sunk they can be linked up without any difficulty, there being no necessity to increase the section of the main cables owing to the new load, as the value of the current remains the same. The efficiency of the system is high, owing to the large percentage of energy returned to it because of its excellent regenerative capacity.

BUREAU OF MINES returns show the following output from the mines and plants of Ontario for the six months ended June 30:

		Value.
Gold, oz. ....	11,854	\$ 235,198
Silver, oz. ....	14,258,403	7,936,600
Copper, tons ....	5,170	736,469
Nickel, tons ....	10,179	2,166,895
Iron ore, tons ....	12,342	33,060
Pig iron, tons ....	283,926	3,942,638
Lead ore, tons ....	17	849
Cobalt, etc., lb. ....	854,324	192,073

## Ore Reserves and Life Extension

By MORTON WEBBER

A basic advance made in mine valuing is the classification of developed ore according to the various degrees of risk involved. These risks may be regarded as the varying possibilities of discrepancy between the appraised metal content of the blocks of ore standing in a mine and the metal content known after their removal.

Ore which is a certainty is so surrounded by sampled faces sufficiently near to each other, taking into consideration the particular type of deposit, that the continuity of ore of that grade into the centre of the block can be regarded as assured. This is axiomatic. The multiplication of sampled faces therefore decreases the risk, and conversely. As the number of levels, shafts, raises, and winzes which can be sampled varies throughout every mine, there are varying degrees of risk. Reform in mine valuing involves dividing such blocks into classes dependent upon risk, so named that the corresponding degree of risk attached to any block will be understood by others. In valuation such blocks, depending upon the number of faces exposed, are segregated and named according to the class of risk to which they belong. Experience in the application of this theory of risk has shown that little is gained by an increase beyond 'three comparative degrees.' It is imperative in competent valuation to consider other forms of risk, such as the risk of metal prices, the risk in estimating costs, and the risk of metallurgical efficiency, especially when basing an opinion on surface evidence. These, however, should not be referred to as 'degrees' of risk in a comparative sense. This conveys an impression of tangibility, while such risks are purely nebulous. The three groups in which ore blocks are segregated are called 'positive ore,' 'probable ore,' and 'possible ore.' Ore-blocks which can be sampled on four sides are regarded as positive ore, and are eligible as a first-class risk. They approach nearest the ideal referred to above. Blocks which can be sampled on three sides are regarded as 'probable ore,' the questionable grade of the unknown fourth side increasing the hazard. Blocks where data for only two sides is available are only eligible for the risk under 'possible ore.'

There is yet another class called 'life extension.' Owing to the nature of the mining industry, this has great significance. Different engineers use different expressions to distinguish this phase; my preference is for the term here used. This class constitutes a risk, especially if it is a factor in a mine appraisal. In young mines this is frequently essential. In my judgment, this class is better considered from a different standpoint, as the application of the word 'risk' indicates a connection with the three universally recognized risks, which are based on tangible specific data. To refer to it as a risk suggests something less valuable than possible ore, being further removed from the ideal four-sided condition. It therefore seems more logical to regard life extension not as a risk, but as a possibility. If a money equivalent is attached, it should be considered from the more logical basis of 'good-will.' Life extension should therefore be considered separately, as it is a phase by itself and is not necessarily connected with or dependent on the three main classes into which ore-blocks are grouped. This is a fact that should be thoroughly understood. A frequent mistake is made in regarding the importance of positive ore, probable ore, possible ore, and life extension in the order presented. This is illogical. Mines are always drawing nearer exhaustion, and their ore reserves are frequently greatest just before the epoch when ore-shoots commence to pinch or the grade decrease in depth. A mine when first opened is seldom provided with a large ore reserve, yet this is a period when its life extension is generally most valuable.

The energetic but expensive policy of developing ore on four sides does not alter the natural characteristics of orebodies. The developing of extensive four-sided ore reserves is commonly due to the requirements of corporations that have their shares listed on the stock exchange. The annual presenting of book valuation is essential. This refinement has done much to increase the repute of the mining industry, but a large ore reserve should not materially influence the judgment of the mine valuer in respect to life extension. The risk beyond exposed faces is not necessarily minimized; merely more geological facts are presented. In a mine having a laterally short 'orebody,' the risk in prognosticating future extension, is greater. The maintaining of four to six, or even more, levels below the immediate productive zone of the mine will bring the lowest level proportionately nearer the horizon where ore-shoots terminate. To associate life extension with ore reserves in any fundamental way is therefore illogical and will lead to unreasonable results.

A longitudinal section showing the contraction of ore-shoots with each succeeding level offers unmistakable evidence. Simultaneously, administrative policy may exhibit an abnormal proportion of unconnected blocks of probable ore, accompanied by an even greater proportion of possible ore. Such seductive evidence might convey the conclusion that the future possibilities were better than they are. The evidence supplied by the development of a succeeding lower level may show the termination of the ore-shoot or the creeping in of low-grade primary sulphides.

One method of life extension appraisal was emphasized several years ago by J. H. Curle. The net profit of ore reserves was estimated to represent from 65 to 80% of the total valuation. The remainder was allocated to life extension. The proportion allocated substantially depends on the condition of the bottom levels. In this way the possibilities are compounded by formula with the known ore of a mine. This basis of appraisal is still popular with many engineers. In my judgment it is illogical and as likely to overvalue possibilities as to be conservative. Mr. Curle's system has been, however, of great value. It teaches the investor to always consider mining from the business-like standpoint of assets. Its defect is that the relative magnitude of the ore reserve in any particular mine is largely a matter of administrative policy. A small mill in combination with an energetic policy of development will result in a mine maintaining a large ore reserve. A large mill in combination with an ordinary development policy will not permit of a large ore reserve. The same mine might be developed down to the same horizon under different administrative policies and exhibit identical evidence of permanence. Therefore any method of appraisal that depends on formula would result in entirely different valuations of the same mine bottom, or lateral extensions, as the case may be. Such a method of valuation disregards the primary basis on which the appraisal of life extension should rest, namely, geological evidence. It disregards the widely varying geologic nature of different mines, and it ignores the important collateral evidence supplied by adjacent properties. The prognosis of life extension should rest on how far ore-shoots may be expected to extend beyond the limits of present development. It is illogical to vitiate this by introducing the transient factor of the remaining ore enclosed within development extremities.

Professional experience in this country and Europe with capitalists who operate mines, will reveal occasional friction between engineers and their sometimes plutocratic employers. While this has in some cases been caused by the engineer being insufficiently pliable to see things that are

not to be seen and unable to imagine that which is absurd, I believe that the boot is frequently on the other leg. Future possibilities are what mine operators want. Life extension, instead of being regarded as fourth in importance, as hitherto explained, is, in my judgment, of paramount importance. A carefully formulated opinion of this aspect should constitute a primary part of a report either for or against a property, and its evasion or its limitation by formula must handicap the usefulness of an engineer. The fundamental nature of mining, which requires the return of capital before dividends can be considered profit, demands the incentive of large speculative possibilities. If the critic who doubts this should attempt to promote a property offering as its only attraction a history of uniform production, he would find that a large proportion of those who would be otherwise interested prefer an investment in a railroad, or some other constructive enterprise that may go on indefinitely depending on trade. The mining engineer has to deal with conditions as well as ethics. He belongs to a profession which has the privilege, or otherwise, depending upon viewpoint, of meeting the requirements of finance and trade. In this he differs from the doctor, lawyer, and his less responsible brother the geologist. The thorough but conservative understanding of this fact has perhaps helped some engineers to success.

The accompanying illustrations are longitudinal projections of three gold mines. They illustrate life extension as a distinct factor. Fig. 1 represents the frequent condition of the simultaneous curtailment of orebodies at depth, at an epoch when ore reserves are greatest.

FIG. 1.

Fig. 2 represents a famous producer. It has an active stock exchange demand. To meet the requirements of a large list of stockholders, the administration has preserved the policy of maintaining an ore reserve averaging three to four years ahead of the immediate necessities of the mill. Dividends aggregating \$3,000,000 have been paid. At the last annual meeting, shareholders were informed that the present net profit in the ore reserves was estimated at \$2,500,000. Four-fifths of this estimate was due to ore developed on at least three sides. Life extension was referred to as normal, the ore of the lowest level being similar to the preceding two above.

Fig. 3 represents a mine of markedly dissimilar characteristics. The property is owned by a private corporation. There are no popular market conditions to meet. Development has been primarily done in the search for new sources of ore supply. Utilizing the major portion of the money supplied for development in this way is considered preferable to blocking out ore on four sides.

The deposit is a replacement along a main fracture plane in andesite. The impregnation of the walls varies within wide limits. This is characteristic of the deposit. Blocking out ore on four sides in a deposit of this type is expensive and often financially prohibitive. The property

FIG. 2.

has earned \$800,000. The present known ore reserve of the mine is estimated at \$1,000,000 net. This figure is deduced by taking all the ore down to workable two-sided ore. This aggregate is then subjected to a process of elimination in order to arrive at a net figure that can be relied upon until the present faces are further developed and

FIG. 3.

additional faces exposed. The result is as presented. This procedure will be understood by those familiar with this type of metasomatic replacement deposit. As a sequence to such a development program, when the data were compiled the mine could only show \$300,000 net in four-sided ore.

From the viewpoint of book value in ore reserves, Fig. 3 presents a poor comparison with Fig. 2. Notwithstanding the disproportion in the net value of ore reserves, in event of both properties being for sale at the same price, I would prefer No. 3. This statement is made with the proviso that the basis of purchase should be time payments with the privilege of substantially discounting at the option of the purchaser. In the case presented, the life extension possibilities of Fig. 3 constitute the greatest asset of the property.

Comparing them in further detail, it is seen that the uniform production of Fig. 2 has been phenomenal. In the light of past experience in depth, a not unusual risk

would be contracted in anticipating similar extension for three succeeding levels. This would be 300 ft. Each succeeding zone is, however, drawing proportionately nearer the horizon where ore-shoots will eventually terminate. Two other levels may reveal similar tooth-shaped barren lenses as shown by subsequent development below A B in Fig. 1. Previously to the unmistakable evidence subsequently furnished by the succeeding horizons below A B, the mine never looked better, and simultaneously the ore reserve was at its greatest. In my judgment the really superficial nature of ore deposits, even apart from secondary alteration, should be thoroughly understood. A chart showing the productive depth of twenty producing mines will prove this.

Fig. 3 presents the reverse condition. Instead of being dependent on the extension of a bottom that is now down at a depth of 1750 ft., it has not only two bottoms, but also two sides. The latter will advance through comparatively superficial zones where the recognized enriching effects of secondary alteration are most prevalent. Physically the mine offers the attraction of adit development. Assuming equality in economic location, this will permit working costs with which the deep-level conditions of Fig. 2 could not compete. Grade for grade, Fig. 3 will be more profitable, and ore zones will yield a profit that in Fig. 2 could not be treated.

It is hoped that the foregoing will show the varied conditions that cannot be computed by formula, or any process of measurement available to the valuing engineer. The consideration of life extension should be a matter of individual judgment of the case presented. There is no formula for judgment, which must rest on a proper balancing of geologic and economic evidence. The only prescription is experience founded on a college training in combination with native business ability. Business ability is essential in the proper balancing of economic evidence and delivering an opinion on the selling conditions.

Prospective life must wholly depend, I believe, on how far ore can be reasonably expected to continue beyond exposed faces. This can be converted into expected tonnage. This convertible term can then be introduced into an annual report or considered separately as a factor in a sale. If the price asked for a property requires an unreasonable or dangerous proportion of the total price to rest on expected ore, better terms must be demanded.

As a result of long observation, mainly of mines partly or completely exhausted, geologists have evolved certain hypotheses. While remaining still hypotheses, with their inherent fallibility, they have widely accounted for underground experience. They are so important that no valuing engineer is properly equipped to deliver judgment on the life extension of a mine without a thorough grasp of the underlying principles laid down by Lindgren, Emmons, and Van Hise.

There are five geologic heads under which life extension should be considered. After presenting them they will be discussed seriatim. It should be understood, however, that in the space afforded, it is difficult to present even a digest. The five geologic heads are:

- I. Character of the deposit in respect to past experience of the geology of similar deposits.
- II. Size of the deposit in respect to length and width.
- III. Secondary alteration.
- IV. Depth to which the mine has been worked.
- V. Experience in the immediate neighborhood as to the persistence and continuity of orebodies in depth.<sup>1</sup>

#### CHARACTER OF THE DEPOSIT IN RESPECT TO EXPERIENCE OF THE GEOLOGY OF SIMILAR DEPOSITS

In the study of continuity, ore deposits may be roughly divided into three classes: (A) Infiltration deposits, such as, for example, the South African banket and the copper conglomerates of Lake Superior. The continuity of ore in these deposits is a maximum. Tonnage estima-

tion can often be computed from data supplied from levels 300 ft. apart. (B) Deposits depending on profound earth movements. To this class belong fissure and contact veins. Opinion as to the continuity of ore must be largely based on local experience, as, for example, the persistence of the ore-shoots of the San Juan district in comparison with others that show a sad mortality before even entering the zone of secondary enrichment. (C) Deposits depending upon replacement or impregnation along fissures or other openings. This class presents widely differing phenomena, and generalization is impossible. Valuable producers of this class are found in Tonopah and Goldfield, Nevada, Mexico, and Western Australia. Continuity beyond sampled faces should generally be considered with great caution. In contrast to these are the copper deposits of Arizona and Utah, the result of the impregnation of porphyritic rock, that exhibit great regularity. This classification is only intended to conduce to simplicity of explanation. In practice a deposit may exhibit characteristics of more than one class.

#### SIZE OF THE DEPOSIT IN RESPECT TO LENGTH AND WIDTH

From a structural standpoint, eliminating the increase of risk from one horizon to another in approaching the termination of secondary enrichment, the depth of an ore-shoot bears some proportion to its length. Ore deposits, especially of the fissure type, are usually lenticular in shape, therefore the vertical aggregate height, above and below any horizon, should fall somewhere between the lengths of the minor and major axes. The practical limitation of this assumption is that it is impossible to know the vertical position of any level on which opinion is based. The greater proportion of the ore may be above that horizon, leaving only a small remainder below. The line A B, Fig. 1, will illustrate this.

As the risk beyond exposures is in proportion to the distance assumed, the advantages in length and width of a deposit are best illustrated from a purely commercial standpoint. As explained, life extension can be represented in additional area expected, and this expectation should be based on the geologic evidence of the particular case. To illustrate, assume that in a purchase the valuation of a hypothetical mine requires \$50,000 of the total price to be represented in life extension. Assuming that the orebody on the lowest level is 400 ft. long and of an average width of 5 ft., every additional foot of depth will equal approximately 140 tons. Should the orebody be only 300 ft., with an average width of 3 ft., every additional foot will produce 60 tons. Assuming an expected profit of \$3 per ton in both cases, the risk in extension in the larger orebody is only approximately 120 ft., compared with 280 ft. in the case of the smaller. The operation of the larger deposit should offer not only lower underground cost, but also the economic attraction of a larger reduction plant.

#### SECONDARY ALTERATION

The solubility of the metals of many ores in descending solutions is generally understood. The vast commercial effect of such metal migrations on the lower sulphide zones has, however, only comparatively recently been recognized. In considering the extension of ore in depth this phase demands the most thorough investigation. Not only do the upper ore zones become oxidized by descending solutions, but a complex migration of metals takes place with re-precipitation lower down. These phenomena differentially enrich the upper oxide zones in the least soluble minerals, and enrich the lower sulphide zones in re-precipitated minerals. The upper zones are robbed of easily soluble minerals, and therefore, in proportion, enriched per original unit of content in those minerals more able to withstand migration. The effect of migration to lower horizons has in many cases completely altered the character of a mine. The Mt. Morgan copper mine, in Australia, was originally a famous gold producer. The gold content for many years averaged \$20 per ton. Leadville is now mainly a producer of zinc. The copper mines

<sup>1</sup>Estimating and Valuing the Future of Mines, Morton Webber, *Mining and Scientific Press*, Sept. 16, 1911.

of Butte were once important in the production of silver.

The most reasonable explanation for these phenomena is based on simple chemical properties of the metals. Zinc, iron, and lead are in common primary combination. These metals are rendered soluble by oxidizing agents in the order presented. Their ease of precipitation as sulphides is in reverse order. Gold and silver are the most insoluble metals that play an important part in mining. Copper, on the other hand, may be regarded as one of the most soluble. In solution and migration, ore deposits may be considered to have four horizons. These horizons are seldom sharply defined. (A) The zone near the surface where the main characteristic is oxidation, and the leaching of soluble contents. This horizon may be differentially enriched by silver and gold, in consequence of its abandonment by the metals that have migrated. (B) A lower oxide zone where the predominating feature is the precipitation of the metals as carbonates and oxides. (C) The upper horizon of the original orebody, where the characteristic is enrichment by re-precipitation as sulphides of the metals that came from above. (D) The region below the influence of secondary alteration, where the orebody is unaltered.

In districts of rough topography situated in wet climates, surface denudation rapidly follows alteration and migration. This is especially the case when, as the result of glaciation, the primary ore may appear at the surface. Flat and arid country offers more favorable conditions. Denudation is slow and conditions are favorable for the deep penetration of oxidizing solutions, and consequent secondary enrichment.

As explained, zinc, iron, and lead are soluble in sequence and precipitate in inverse order. The progress of oxidation of a complex vein containing these metals, together with gold and silver, will explain the theory of secondary alteration: The migration of surface waters will result in the easy leaching of zinc and iron. There is, therefore, a differential enrichment per unit area, of the gold, silver, and lead that remain. Such lead as goes into solution quickly precipitates. In this way the lead zone is extended. Such silver as may go into solution will quickly precipitate with the lead, explaining the formation of silver bonanzas. Similar reasoning will account for the varying characteristics of the rearrangement of the other metals. The oxidized zone contains an abnormal differential enrichment of gold and silver. The silver-lead zone contains silver bonanzas, the aggregations being due to the ease with which silver precipitates with a lead reagent. Coming to the lead-zinc zone, some of the zinc now having precipitated, this changes with depth into zinc-lead and iron, with the former metal predominant. This finally merges into primary low-grade ore, containing gold, silver, lead, zinc, and iron.

In copper deposits the comparative ease of solution, migration, and re-precipitation frequently results in extensive impoverishment near the surface. The familiar 'iron hat' at the surface, with oxides and carbonates forming the second zone, enriched by secondary copper sulphides at the third, with copper-iron sulphides below, is characteristic. The primary deposits of Michigan previously referred to, should not be confused with this class. A majority of productive copper mines can be tabulated in this way that finally merge into uncommercial unaltered primary ore.

In a general way, the following facts that depend on secondary alteration should be remembered. Oxidation influences treatment problems. Some oxidized gold ores that can be treated profitably become unprofitable in the sulphide zone, or require a new mill. Conversely, low-grade ores of lead, copper, and zinc may be profitably treated by concentration when in sulphide form, but as oxides are unprofitable. Copper ores show maximum enrichment at the base of the oxide zone and top of the sulphide zone. Silver and silver-lead bonanzas are usually found at this junction. Lead-zinc ores exhibit lead enrichment and zinc impoverishment in the lower oxide and upper

sulphide zone; the converse taking place with depth. The sad mortality of gold mines on entering the sulphide zone is directly due to the fact that the oxidized portions were only rendered profitable by differential enrichment.

#### DEPTH TO WHICH THE MINE HAS BEEN WORKED

Mines have three phases of existence: youth, productive middle life, and a decrepit old age. As a rule, the most speculatively attractive period in the life of a mine is the transition from youth to the productive possibilities of middle life. Like children, there is great mortality in the prospective or youthful epoch of their existence. To forecast an extension of ore in the purely prospective life of a mine is assuming extreme risk and hazard, but as exploration in depth progresses, the property either dies off in its youth or the risk materially decreases. The mine then emerges to a period of maximum production with minimum risk. This in turn is succeeded by a return of increasing risk. This hazard accumulates as the expectations of life are dependent on horizons approaching the extremities of secondary enrichment and the generally superficial boundaries of ore deposits.

#### EXPERIENCE IN THE IMMEDIATE NEIGHBORHOOD AS TO THE PERSISTENCE AND CONTINUITY OF OREBODIES AT DEPTH

Neighboring mines are usually dependent on similar geologic conditions. The depth and lateral extension of the orebodies of adjoining mines is therefore of infinite value. Many important discoveries have been made by closely following experience of adjoining properties. In certain cases the value of a mine has increased on reasonable grounds, as the outcome of the favorable extension of the orebodies by nearby development. Special examples of this condition, bearing on both the valuation and administration of mines, are to be found in Nevada, Mexico, and Western Australia.

The minimum or basal value of a mine is the net profit of its existing ore reserves. In the case of base-metal mines, this estimate should be computed on a metal price somewhere between the average over a past period and the low peaks during cycles of trade depression. As sub-normal metal prices are introduced to conservatively compute a metal market that can be relied upon, likewise, for the same reason, supernormal operating costs should be introduced. This result produces the *A* value of a mine. To this should be added the *B* value, or the asset of life extension, which should represent the judgment regarding this individual case under the five geologic heads presented. As the *A* value was founded on a sub-normal estimate of metal prices, the profits to be expected as the outcome of operating under normal metal marketing conditions should be introduced. This is the *C* value. To this should be added the *D* value: the result of expected operating economies, the outcome of modern plant and efficient management. In this way the total value of a mine may be regarded as  $A + B + C + D$ . The able engineer who has profited by experience will place these facts unreservedly before his employer. The serious mine-operator will require them of his engineer.

PRACTICALLY no work is being done on the new discovery at Kumalpi, mentioned in special correspondence from Kalgoorlie in the issue of September 14. The original prospectors, who found a large nugget, have about 20 sacks of ore on hand. No fresh discoveries have been made along the supposed line of lode. An area of 1333 acres has been staked, and applied for at the registrar's office. A geologist has been examining the Kumalpi field, and the water-supply is receiving attention. The district inspector of mines stated that "if, in cross-cutting the oxide of iron formations in the Gessner and Huffer claim, gold should be found, it will be an important development for the field." Three new mills, all using Huntington mills and cyanide treatment, to crush 1250, 1250, and 12,000 tons per month respectively, have just been started, the first two at Kalgoorlie, and the large one at Ora Banda, about 40 miles northeast of the latter place.

# The Institute Constitution and By-Laws

## Proposed Changes

The following amendments to the constitution and by-laws of the American Institute of Mining Engineers were proposed by G. C. Stone and C. R. Corning, at the adjourned annual meeting of the Institute, in New York, October 7. These will be voted upon at the annual meeting in February next.

### CONSTITUTION.

Article I is to remain unchanged.

### ARTICLE II.

Replace Section 1 by the following: 'The membership of the Institute shall comprise four classes, namely:

1. Members.
2. Honorary Members.
3. Associates.
4. Junior Members.

Honorary Members, Junior Members and affiliated Societies in their corporate character shall have no votes. Members and Associates residing within the United States of America, United States of Mexico and Dominion of Canada, shall be entitled to vote at the meetings of the Institute in person or by proxy, or as hereafter provided for by letter ballot.'

*Explanatory Comment.* Class 4 is added; the object being to bring in students in schools of Mining and to give them the advantages of membership under favorable conditions and without the payment of an initiation fee. Also to permit voting by letter ballot.

Section 2. No change.

Section 3. No change except to add after the last sentence, 'As Junior Members, any student in good standing in engineering schools or related educational institutions who has not taken his degree and who is nominated by at least two of his instructors. (A Junior Member may remain such not longer than three years after leaving said educational institution, when he must be passed upon by the membership committee to become a Member or Associate and pay at that time the entrance fee and dues of a Member or Associate).'

Section 4. The portion of this Section reading "Not less than three-fourths of the votes cast shall be necessary to an election. Every person so elected shall become a Member or Associate, as the case may be, upon payment of his first dues as hereinafter described. Each candidate for Honorary Member must be recommended by at least ten Members or Associates, must be approved by the Council, and must be elected by ballot at a meeting of the Board of Directors by unanimous vote of all the Directors present, providing, however, that the number of Honorary Members shall not, at any time, exceed twenty," to be replaced by the following:

'Not less than three-fourths of the votes cast shall be necessary to an election; newly elected candidates shall be immediately notified of their election by the Secretary of the Institute and also by him of their obligations. Every person so elected shall become a Member or Associate or Junior Member of the Institute in the Class to which he is chosen upon payment of his initiation fee if required by this Constitution, and first dues, as hereinafter stated. Each candidate for Honorary Membership must be recommended by at least ten Members or Associates, must be approved by the Council and must be elected by ballot at a meeting of the Board of Directors by the unanimous vote of the Directors present, provided, however, that the number of Honorary Members shall at no time exceed twenty.'

Section 5; reading at present as follows, "If any person elected a Member or Associate does not, within sixty days after notice of his election, accept the same and pay his initiation fee and dues for the current year, his election may be cancelled at the discretion of the Council," to be changed so as to read:

'If any person elected a Member, Associate or Junior Member does not within four months after the mailing of notice of his election accept the same and pay his initiation fee if required and dues for the year in which he was elected his election shall be null and void and he shall be notified thereof by the Secretary of the Institute; providing, however, that if elected in the months of November or December the candidate may, at his option, pay dues only for the ensuing year, in which case he shall be entitled to receive the Bulletin of the Institute for the months of November and December but not the Annual volume of the year during which he was elected to membership.' *Comment.* Four months is substituted for sixty days to admit of remote addresses. Changes make action automatic.

Section 6. No change.

### ARTICLE III. DUES.

Section 1, reading as follows: "The dues of Members and Associates shall be Ten Dollars per annum, payable in advance on the first day of each calendar year. Each newly elected Member or Associate shall pay, when notified of election, an initiation fee of Ten Dollars in addition to the dues for the current year. Honorary Members shall not be liable to initiation fees or dues. Any Member or Associate in arrears for one year, may, at the discretion of the Council, be deprived of the receipt of publications or stricken from the list of Members, provided that he may be restored to membership by the Council on payment of all arrears or may be again proposed and elected after an interval of three years," to be changed to read:

'The dues of Members and Associates shall be Ten Dollars per annum and of Junior Members shall be Five Dollars per annum. All dues shall be payable in advance on the first day of each calendar year, and notice to this effect shall be published in the last number of the Bulletin of each calendar year, and a bill shall be mailed to each Member and Associate on the first day of the month of January in each year stating the amount of dues and date when payable and the penalty and conditions incident to default in payment within the limit of time set by the Constitution.

'Each newly elected Member or Associate shall pay, immediately on notification of his election, an initiation fee of Ten Dollars; Junior Members shall not pay any initiation fee. Honorary Members shall not be liable for initiation fee or dues.

'If any Member, Junior Member or Associate is in arrears for four months the Bulletin shall no longer be sent to him and he shall be notified by the Secretary of the Institute that no publications will be sent him until his arrears are paid.' *Comment.* The changes are made partly to correspond to the new grades of membership, partly to cut off delinquent Members after a reasonable time of non-payment, and partly because of the Postal regulations.

Section 2, reading "Any Member or Associate not in arrears may become, by the payment of One Hundred and Fifty Dollars at one time, a Life Member or Associate; and shall not be liable thereafter to annual dues," to be changed to read:

'Any Member or Associate not in arrears may become, by the payment of One Hundred and Fifty Dollars at one time, a Life Member; and shall not be liable thereafter to annual dues. The fee received from Life Memberships shall be invested by the Directors and only the income of such investment shall be used for current expenses.

'Section 3. The Board of Directors shall have the right at any meeting thereof to increase the dues of the membership for the next ensuing year or years by any sum not to exceed the amount of Five Dollars per annum, such increase of dues to be applicable solely to the extinction of the principle of the landed indebtedness of the Institute. As soon as such indebtedness is paid the dues shall automatically lapse back to the present amounts and this power cease.'

### ARTICLES IV and V.

To stand as in the present Constitution.

### ARTICLE VI.

Section 2. The first sentence, reading "The officers of the corporation shall be a President, Vice-President, Secretary and Treasurer, who shall be elected by the Directors from among their number;" to be changed to read:

'The officers of the corporation shall be a President, Vice-President, Secretary of the Board of Directors, to be known as Secretary of the Institute, also a Treasurer of the Board of Directors who shall be termed the Treasurer of the American Institute of Mining Engineers. All of these shall be elected by the Directors from among their number, excepting the Secretary, who may or may not be a member of the Board.' The remainder of the Section to read as at present.

Section 3 unchanged.

Section 4. In the last sentence, which reads, "Any Director who shall under this Section or in any other manner cease to be a Member of the Board shall at the same time be held to have vacated any other office to which he shall previously have been elected; and the Board shall elect a new incumbent to the said vacant office," change the words "any other office" to read "any other office of the corporation." *Comment.* The change is in the interest of clearness.

Section 5. No change.

### NEW SECTIONS.

'Section 6. No two of the three offices of Secretary, Treasurer or Assistant Secretary of the Board may, under any circumstances, be united in one person.

'Section 7. All salaries or other pecuniary compensations paid by the Institute shall be fixed in advance by the Board of Directors.

'Section 8. The funds of the Institute shall be paid out only by check signed by the Treasurer; or, in case of his absence or disability, either by the President or Vice-President.'

#### ARTICLE VII.

Section 2, reading as follows, "Special meetings of the Board of Directors, at which any business may be transacted, may be called to meet at any time at the office of the Institute in the City of New York, by notice in writing mailed at least five days before the meeting, by the Secretary to each member of the Board at his last known Post Office address, signed either by the President or the Vice-President or by three members of the Board," to be changed so as to read:

'The Board of Directors shall meet once each month in the year, excepting the months of February, July and August, on a regular date to be fixed in advance, for the transaction of such business as may come before them. They shall meet in the month of February as already provided in the Constitution, in Section 1 of this Article.

'Special meetings of the Board at which any business may be transacted may be called to meet at any time and place in the State of New York by notice in writing mailed at least five days before the meeting or by telegram sent at least five days before the date of meeting, by the Secretary of the Board to each member of the Board at his last known Post Office address, on request of the President, Vice-President or three members of the Board.' *Comment.* These changes make mandatory the very desirable practice inaugurated in 1911.

Section 3. Change to read as follows: 'At all meetings of the Board of Directors the presence of three members shall constitute a quorum.'

#### ARTICLE VIII.

Section 1, reading: "The professional, technical, scientific and social interests of the Institute shall be committed to the supervision of a Council composed of a President of the Council, six Vice-Presidents of the Council, a Secretary of the Council, and nine Councilors, who shall be elected from among the Members and Associates of the Institute in the manner hereinafter prescribed. Members of the Council may or may not be members of the Board of Directors," to be changed so as to read:

'The professional, technical, scientific and social interests of the Institute shall be committed to the supervision of the Council composed of a Chairman of the Council, a First Vice-Chairman of the Council, six Vice-Chairmen and nine Councilors, who shall be elected from among the members and associates of the Institute in the manner hereinafter prescribed. Members of the Council may or may not be members of the Board of Directors.'

Section 2 unchanged.

Section 3, which deals with the election at each Annual Meeting of the President, Vice-President and Secretary of the Institute, change President and Vice-President to be Chairman and Vice-Chairman and strike out in the fourth and fifth lines from the bottom the words "A Secretary of the Council to serve for one year." Wherever the words "President of the Council," or "Vice-Presidents" appear they should be respectively replaced by the words 'Chairman' or 'Vice-Chairman' or Vice-Chairmen. *Comment.* Provision is made in proposed Section 6 for a proper election of Secretary of the Council.

Section 4. Unchanged.

Section 5. Replace the present Section reading as follows: "The presence of five members of the Council shall constitute a quorum; but the Council may appoint an Executive Committee, or any business coming within the authority of the Council may be transacted at a regularly called meeting thereof, at which less than a quorum may be present, subject to the approval of a majority of the Council subsequently given in writing to the Secretary and recorded by him with the minutes," with a new Section to read:

'The presence of three members of the Council shall constitute a quorum.'

Abandon Section 6, which will be replaced by Article IX (see below), and add the following new Sections:

'Section 6. At their first meeting after the Annual Meeting the Council, and with the approval of the Board of Directors, shall elect a Secretary of the Council to serve for one year or subject to the pleasure of the Council; and for such salary as may be fixed by the Board of Directors.

'Section 7. The Council shall not finally decide on any course of action involving expense for which appropriations have not been already made without submitting the same to the Board of Directors, with an estimate of the expense, and obtaining the written approval thereof by the Board or of its Finance Committee.

'Section 8. The Council may from time to time in its discretion elect any past Secretary of the Council to the office of Secretary Emeritus to serve for such period and to perform such duties as the Council, with the approval of the Board of Directors, may designate. The incumbent of this office shall

receive such compensation as may be fixed by the Board of Directors. *Comment.* These new sections, 6, 7 and 8, respectively are proposed so as to make the Secretary of the Council directly responsible to the body which he serves; to preclude situations which may have heretofore frequently arisen; and to provide a dignified position, such as does not at the moment exist, for officers of the Institute who retire from service; and yet by their length of association and by eminent service are entitled to continue in dignified association with the membership.

#### ARTICLE IX.

##### *Nominations for Officers, Etc.*

'An official ticket of nomination for officers and places annually falling vacant in the Council and Board of Directors shall be prepared by a Committee on Nominations of which no member shall be, at the time, in the Council or on the Board. This Committee on Nominations shall be appointed by a majority vote of the Council and Board of Directors in joint meeting on recommendations made by the President of the Institute not more than ninety days after the Annual Meeting, and it shall immediately proceed to the selection of candidates and the naming of a ticket. The official ticket thus formulated shall be transmitted to the Secretary of the Institute not later than November 1st of the same year for publication in the November *Bulletin*; and shall be separately printed and mailed to the membership not later than January 1st next following. Any complete or partial ticket of nominees signed by any twenty-five members or associates of the Institute and transmitted to the said Secretary by December 15th shall also be printed and circulated with the official ticket and over the names of the Nominators.

'Nominations may also be made viva voce at the Annual Meeting by any properly qualified voter.'

Present Article IX becomes Article X. Present Article IX, Section 2, becomes Article X, Section 2, as follows:

#### ARTICLE X. (Old ARTICLE IX.)

Section 1. Is to remain unaltered.

Section 2. The first sentence, reading, "A meeting of the Council may be held on the day of the Annual Meeting of the Institute without previous notice," change to read:

'A meeting of the Council shall be held on the day of the Annual Meeting of the Institute with or without previous notice.'

The remainder of the Section the same as at present, except that the last eight words on the last line be changed to read:

'Twenty days before the date of the meeting' in place of "ten days before the date of the meeting."

"ARTICLE X now becomes ARTICLE XI.

#### ARTICLE XI. (Old ARTICLE X.)

Section 1. Unchanged.

Section 2. The first sentence reading, "The copyright of all professional papers communicated to and accepted by the Institute shall be vested in it unless otherwise expressly agreed between the Council and the author," change to read:

'All professional papers communicated to and accepted by the Institute shall be copyrighted at the corporation's expense and the copyright shall be vested in the corporation unless expressly otherwise agreed between the Board of Directors and the author on advice of the Council.'

#### ARTICLE XIII.

##### *Business Manager.*

'The Directors shall appoint a Business Manager who shall, under the instructions of the Board, have charge of the business affairs of the Institute. The duties of the Business Manager shall be such as the Board may assign to him and must not include incurring of expense not provided for by appropriations nor the disbursement of funds except as provided for by the Constitution. The salary of the Manager shall be fixed by the Board and he shall hold office during its pleasure.'

#### ARTICLE XIV.

##### *Subdivisions.*

'The Council, with the approval of the Board of Directors, may authorize the formation of Local Sections and Topical Divisions, or arrange affiliations with other Societies in accordance with this Constitution and the By-Laws.'

ARTICLE XI now becomes ARTICLE XV, not otherwise changed.

ARTICLE XXII becomes ARTICLE XVI, not otherwise changed except to replace in the fourth line the words, "Previous meeting" by the words 'previous business meeting.'

#### BY-LAWS.

##### I. PRESIDING OFFICER.

Reading at present as follows: "At all other meetings of the Institute the President of the Council, or in his absence, one of the Vice-Presidents, if present, shall preside,"

change to read: 'At all other meetings of the Institute the Chairman of the Council, or in his absence the first Vice-Chairman of the Council, or one of the Vice-Chairmen of the Council, if present, shall preside. If none of these be present the meeting shall elect its own Chairman *pro tem.*'

## II. ORDER OF BUSINESS.

Unchanged.

## III. SECRETARY OF THE BOARD OF DIRECTORS.

The first paragraph of this By-Law reading, "The Secretary shall keep a record of the proceedings of all meetings of the Institute. He shall be custodian of the Corporate Seal, of the Minute Books, and of all Legal Documents belonging to the Institute. He shall conduct, on behalf of the Institute, all correspondence relating to business matters, except such as pertains directly to the office of the Treasurer," change so as to read: 'The Secretary of the Board shall keep a record of all business meetings of the Institute in a record book with permanent binding. He shall also be the official custodian of the Corporate Seal, of the Minute Books, and of all legal documents and records belonging to the Institute. *Comment.* The remainder of this first paragraph as it now stands is to be omitted. The second paragraph to remain unchanged.

## IV. SECRETARY OF THE COUNCIL.

The second paragraph reading as follows, "He shall be custodian of all technical or scientific papers submitted to the Institute for its consideration, shall have charge of the editing and printing of all material published by the Institute, and of the distribution thereof, etc.," change to read: 'The Secretary of the Council shall be custodian of all technical or scientific papers submitted to the Institute for its consideration.' The rest of this second paragraph to remain as it is.

Paragraph 3, reading "The Secretary of the Council shall receive a salary to be fixed by the Board of Directors. He may appoint an assistant with the title of Editor, who shall likewise receive a salary to be fixed by the Board of Directors." Change this paragraph so as to omit the first sentence. It is already covered by the general statement that the Board of Directors shall fix all salaries. The last paragraph of this By-Law to remain unchanged.

## V. ASSISTANT SECRETARY.

This By-Law reading as follows, "The Secretary may, with the approval of the Board of Directors, appoint an Assistant to whom both he and the Secretary of the Council may delegate such of his or their duties as he or they may see fit. This Assistant Secretary shall receive such salary as shall be fixed by the Board of Directors, which shall cover his services both to the Secretary and to the Secretary of the Council," to be changed to read: 'The Board of Directors shall, at their first meeting after the annual meeting of the Institute, appoint a Business Manager of the Institute to hold office subject to their pleasure whose duty it shall be to have full charge, under the Board of Directors or such Committees or officials as they may designate, of all of the corporation's business affairs, to collect annual dues, subject to instructions by the Treasurer of the Institute, conduct the business correspondence, and attend to the publication and distribution of such documents, circulars and notices as may be transmitted to him for that purpose by the Chairman of the Committee on Papers and Publications.

'He shall receive such salary as may be fixed by the Board of Directors, and shall give his entire time and attention to the business of the Institute.

'The Board of Directors may appoint an Assistant Secretary of the Board to whom the Secretary of the Board may delegate such of his duties as he may see fit. His salary as determined by the Board of Directors shall cover all of his services, in whatsoever capacity, to the Institute.'

## VI. TREASURER OF THE INSTITUTE.

The last sentence of the first paragraph reading as follows, "He shall report in writing at each annual meeting of the Institute and at every meeting of the Board of Directors at which such report shall be called for, the balance of money on hand, and any existing appropriation which may affect the same," to be changed to read: 'He shall report in writing at each annual meeting of the Institute and at every meeting of the Board of Directors the balance of money on hand and any existing appropriations which may affect the same.'

Paragraph 3 of this By-Law, reading, "The Treasurer may, at his discretion, place funds of the Institute, not at any time exceeding \$5,000, in a special account in a Bank or Trust Company, subject to the draft of the Assistant Treasurer, and may delegate to the Assistant Treasurer

the duty of paying, out of this account, the current expenses of the Institute," to be entirely omitted.

Present By-Law VII dealing with the office of Assistant Treasurer should be entirely omitted as it is not proposed to continue the office of Assistant Treasurer.

## VII. STANDING COMMITTEES.

To the first paragraph reading, "The Standing Committee of the Institute shall be three in number, known respectively as the Finance Committee, the Library Committee and the Committee on Membership," add 'and a Committee on Papers and Publications,' and replace the word "three" in the first line by the word 'four.'

Change, in the third paragraph, the words "President of the Council" to read 'Chairman of the Council.'

Add to this By-Law the following new paragraphs: 'The Committee on Papers and Publications shall consist of not less than ten members. It shall be appointed by the Board of Directors at its first meeting after the Annual Meeting in each year, and one of the appointees be named by the Council as Chairman; all members to be appointed for one year. It shall be the duty of the Chairman of this Committee to receive all papers sent to the Institute for publication and all circulars and announcements which it is proposed to issue in the name of the Institute, to distribute them to the proper members of the Committee for their consideration, to receive them back and to transmit them to the editor and from him to the Business Manager for printing and distribution. All matter intended for publication shall be submitted to this Committee and shall not be published without its approval. This Committee shall have power to make its own rules subject to the approval of the Board of Directors. This Committee shall have power to add to its own membership, any such additions to be subject to the approval of the Board of Directors.'

## VIII. EDITOR.

'At its first meeting after the Annual Meeting, the Council shall nominate, subject to appointment by the Board of Directors, to hold office for one year, an Editor whose duty it shall be to edit such papers as he may receive from the Chairman of the Committee on Papers and Publications and to transmit them back through the Chairman of such Committee to the Business Manager of the Institute for printing and distribution.'

## IX. FINANCE COMMITTEE.

In the first paragraph, which reads, "It shall be the duty of the Finance Committee to inquire into and examine the financial condition of the Institute, and to consider ways and means of increasing its revenue and of limiting its expenses. It shall report from time to time to the Board as often as it may deem expedient, and whenever it shall be directed so to do; and the Treasurer shall at all times furnish it with such statements and information as it may desire," change the second sentence so that it shall read: 'It shall report at each monthly meeting of the Directors, and whenever it shall be directed to do so; and the Treasurer shall at all times furnish it with such statements and information as it may desire.'

Omit, in the third sentence, "It may, at any time, examine the books and vouchers of the Treasurer and Assistant Treasurer," the last three words "and Assistant Treasurer." Add to this By-Law the following new paragraphs:

'The Finance Committee shall present a budget to the Directors at the meeting preceding the Annual Meeting of the Institute. This budget shall give an itemized estimate of the receipts and expenses of the Institute for the ensuing year. The Directors shall pass on this budget, modifying it as they consider necessary, and make definite detailed appropriations for the following year.

'The Finance Committee shall check and approve all bills presented for payment and shall not authorize any payments in excess of the appropriations. If at any time any of the appropriations seem in danger of being exceeded, the Finance Committee shall report the same to the Directors.

'All bills, accounts, salaries, pay rolls and claims of every kind against the Institute shall, before being paid, be examined by the Finance Committee and be approved by at least one member of the Committee.' Remainder of the By-Law as at present.

## X. LIBRARY COMMITTEE.

Add to the second sentence of the first paragraph, reading, "It shall on the first day of May each year receive from the Secretary of the Council and receipt for the same to him all the volumes of Transactions for the preceding year not then distributed by said Secretary," the words, 'and shall audit and compare the number of documents of each kind received during the year with those distributed and those turned over to it.'

In the second paragraph reading in part, "It shall cause to be kept, under the direction of the Assistant Secretary,

a catalogue of all books in the Library," etc., replace the words "Assistant Secretary" by the words 'Business Manager.'

#### XI. COMMITTEE ON MEMBERSHIP.

Replace this By-Law, reading, "All nominations for Members or Associates of the Institute shall be submitted to and passed upon by the Committee on Membership, who shall report thereon to the Council. It shall receive and consider all communications respecting candidates, and shall make diligent inquiry as to the character and qualifications of each one. Its proceedings shall be secret and confidential. No member of the Committee shall propose any candidate," by the following: "All nominations for Members or Associates of the Institute shall be submitted to and passed upon by the Committee on Membership. This Committee shall meet at least once in each calendar month commencing with the month of January each year with the exceptions of the months of July and August. It shall receive and consider all communications respecting candidates and shall make diligent inquiry as to the character and qualifications of each one. Its proceedings shall be secret and confidential. No member of the Committee shall propose any candidate."

By-Laws 12, 13 and 14 to remain unchanged. Then insert a new By-Law, which will become Number 15, as follows:

#### XV. OBLIGATIONS TO MEMBERS.

'Any member of whatever grade whose dues are paid within the limits set by Section 1, Article III of the Constitution shall receive the *Bulletin*; and all members and associates who pay Ten Dollars annual dues, also all life and honorary members, shall receive in addition the *Transactions*.'

To the foregoing By-Laws add the following new ones:

#### XVI. LOCAL SECTIONS.

'Section 1. A Local Section of the Institute may be authorized by the Council at the written request of twenty-five members of the Institute residing in the territory comprising the proposed Section.

'Section 2. Any Member of the American Institute of Mining Engineers who shall be a resident of or whose principal business shall lie within the geographical area allotted to a given Section by the Council of the Institute shall be eligible as a Member of the Local Section and shall become such on due proposal by two members in good standing in the Local Section and on election by the officers of this Section.

'Section 3. The Council shall define the territory of the Sections and shall have the right to adjust it at any time.

'Section 4. Local Sections shall elect their own officers and make rules for the government of the Section, subject to the approval of the Council and providing they be not inconsistent with the Constitution and By-Laws of the Institute. The Council shall have the right to amend, annul or add to these rules.

'Section 5. The officers of a Local Section shall be a Chairman, Vice-Chairman, a Secretary-Treasurer and an Executive Committee. The Chairman, Vice-Chairman and Secretary shall be members of the Executive Committee ex officio. These officers shall hold office for a year or until their successors are elected.

'Section 6. A Local Section may receive for its own uses and with consent of and on appropriation by the Board of Directors an amount not exceeding 10% of the annual dues of its members and in no case exceeding \$250 a year, such amount to be drawn from the treasury of the Institute and expended in accordance with the rules to be made by the Directors. If the expenses of the Section exceed the amount so provided, the difference must be made up by voluntary contributions; in no case shall the members be assessed for local purposes.

'Section 7. The Council or the Board of Directors shall have the right to dissolve any Local Section.

'Section 8. Each Local Section shall, by the 1st of February in each year, furnish the Board of Directors of the Institute with an annual financial statement of the Section in the form which may be specified by the Board of the Institute.

'Section 9. The Board of Directors shall dissolve any Local Section whose annual financial statement shows that it is unable to meet its expenses.'

#### XVII. DIVISIONS.

'Section 1. Professional groups to be known as Divisions of the Institute and to be organized from its members, may be authorized by the Council with the assent of the Board of Directors. Any Member of the Institute may register for membership in any Division in which he is interested and may resign therefrom providing he be under no financial obligation thereto.

'Section 2. The officers of the Division shall be a Chairman, one or more Vice-Chairmen, a Secretary-Treasurer, and an Executive Committee. The Chairman, Vice-

Chairman and Secretary shall be ex officio members of the Executive Committee of the Division. All officers of Divisions shall be elected annually by letter ballot by the members of the Divisions, and shall take office at the close of the meeting at which they are elected. They shall hold office for one year or until their successors are elected.

'Section 3. A Division shall have the right to make rules for its own government, subject to the approval of the Council and the Board of Directors, not inconsistent with the Constitution and By-Laws of the Institute. The Council or Board of Directors shall have the right to amend, annul or add to these rules.

'Section 4. Any Division may raise or collect funds to be expended for its own purposes and may have the entire management and control of such funds in so far as said management or control does not conflict with the provisions of the Constitution and By-Laws of the Institute.

'Section 5. The Council or Board of Directors shall have the right to recommend the dissolution of any Division subject to approval of such recommendation at any annual meeting of the Institute, in which case the net property of such Division shall be divided pro rata among all members thereof in good standing.

'Section 6. Each Division shall furnish the Board of Directors on the 1st of February in each year an annual financial statement of its affairs in such form as the Board of Directors may require.'

#### XVIII. AFFILIATION WITH OTHER SOCIETIES.

'At the request of the Council, or of its own initiative, the Board of Directors may arrange for affiliation of other Societies having objects allied to those of the Institute. Provided:—

'A. That the total membership shall be qualified to become and that at least three-quarters of the members desiring affiliation shall be, or become, members of the Institute; and that the affiliated Society shall pay to the Institute, out of its funds, an annual contribution for each of its members not a member of the Institute equal to the dues he would have paid if a member.

'B. After affiliation membership in the Institute shall be a prerequisite qualification for admission to such Society.

'C. No member of such affiliated Society who is not also a member of the Institute shall have the right to vote or hold office in the Institute or attend business meetings, but he shall have all the other rights of membership.

'D. Such Societies may elect their own officers and retain and maintain their own Constitution and By-Laws provided the same do not at any time conflict with the Constitution and By-Laws of the Institute and that they are approved of by the Board of Directors of the Institute.

'E. Such affiliated Societies shall have the right to assess dues on their members in addition to the dues of the Institute and shall have the exclusive control of all funds so raised.

'F. All papers and transactions of such an affiliated Society shall be published in the *Bulletin* and *Transactions* of the Institute if approved by the Committee on Papers and Publications, and if not in conflict with the Constitution and By-Laws of the Institute. All members of such affiliated Societies shall receive all of the publications of the Institute on the same terms as the members of the Institute. Any such Society will retain its right to issue special publications under its own name, which must be announced in the *Bulletin*, in which case all of the members of the Institute shall be entitled to receive such publications free of charge.

'G. The connection between such a Society and the Institute may be terminated by either giving six months' notice and settling all indebtedness.'

Replace the present By-Law XV, concerning membership, which reads, "These By-Laws may at any time be altered or amended by a vote of two-thirds of the Board of Directors, or by the Members, at a business meeting of the Institute, in the same manner provided for amendments of the Constitution in Article XII thereof," by a new By-Law to read:

#### XIX.

'The nomination tickets mailed, as provided for in the Constitution, shall be accompanied by adhesive envelopes marked "Ballot," addressed to the Secretary of the Institute and with a space marked "Member's Name" in the upper left hand corner. Each member may seal up his ballot in this envelope marked "Ballot" and writing his name and address upon the letter mail the same to the Secretary, who shall give them unopened to a Committee of three tellers to be appointed by the Board of Directors at their regular meeting in January immediately preceding the annual meeting. The tellers may receive the ballot at any time within three days preceding the opening of the session of the annual meeting of the same year.

'In case of failure to act on the part of the Board of Directors, or in case at time of meeting there should be no

tellers or a lesser number than three it shall be the duty of the presiding officer at the annual meeting to appoint sufficient tellers to make up the number of three.

#### XX AMENDMENTS.

'A. Amendments to these By-Laws may be proposed at any regularly convened business meeting of the Institute or adjournment of such, to be voted upon at the next succeeding business meeting or its adjournment, by any member or associate in good standing at the time and providing they be submitted in writing to such meeting. Or they may be proposed for action at such meeting by sending the same in writing to the Board of Directors so that they are received by them at least sixty days before the meeting at which they are to be passed upon, and providing they may be endorsed by the signatures of at least twenty members or associates in good standing at the time.

'It shall be the duty of the Board of Directors to have all such proposals printed in the next succeeding issue of the *Bulletin* and to provide proper facilities in the form of proxies to vote thereon at the meeting. At the meeting at which they are voted on they may be amended in form but not in substance.

'B. Amendments to these By-Laws may also be made by a joint vote of a majority of the Directors and Council, provided the amendments have been proposed at a meeting of the Board of Directors or of the Council and copies of the same sent to all the members of both bodies at least twenty days before the meeting at which they are voted on. At the latter meeting they may be amended in form but not in substance. Voting may be by letter ballot sent to the Secretary of the Board of Directors.'

### Action of Oxidizing Agents on the Velocity of Solution of Gold in Potassium Cyanide

By suspending a piece of Au for 10 minutes in a 0.2 N solution of KCN saturated with air and determining the loss of weight both in absence and in presence of other substances, the following results were obtained by Ya. Mikhailenko and M. I. Meshcheryakov, as given in the *Jour. Russ. Phys. Chem. Soc.*, 44, 567-70: Introduction of H ions gradually diminishes the velocity of solution, an excess of them entirely arresting the reaction. OH ions do not accelerate the solution, and an excess of them has a retarding influence. In neutral solution, the following substances have no influence on the velocity: quinone,  $\text{Na}_2\text{SnO}_3 \cdot 3\text{H}_2\text{O}$ ,  $\text{KBrO}_3$ ,  $\text{KIO}_3$ ,  $\text{KClO}_3$ ,  $\text{Hg}(\text{CN})_2$ ,  $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ , while  $\text{KClO}_4$ ,  $\text{KMnO}_4$ ,  $\text{NH}_4\text{SO}_4$ ,  $\text{Na}_2\text{O}$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{NaSO}_4$ ,  $\text{Br}$ ,  $\text{K}_3\text{Fe}(\text{CN})_6$ , and  $\text{KCO}_3$  accelerate the solution. Taking the accelerating influence of  $\text{KClO}_4$  (which is not large) as unit, the influence of the following substances can be represented as follows:  $\text{KIO}_3$  or  $\text{KCO}_3$ , 2,  $\text{NH}_4\text{SO}_4$ , 3,  $\text{KSO}_4$ ,  $\text{NaSO}_4$ , and  $\text{Na}_2\text{O}$ , 4,  $\text{K}_3\text{Fe}(\text{CN})_6$ , 5. The accelerating influence of these substances increases with their concentrations, but only up to a certain limit, above which they begin to exercise a retarding effect. This maximum is 0.02 of an equivalent (*E*) for  $\text{Na}_2\text{O}_2$  and  $\text{NH}_4\text{SO}_4$ , 0.04 *E* for  $\text{K}_3\text{Fe}(\text{CN})_6$ ,  $\text{NaSO}_4$  and  $\text{KIO}_3$ , 0.1 *E* for  $\text{KSO}_4$ , and 0.2 *E* for  $\text{KCO}_3$ . The minimum amount capable of accelerating the reaction is in most cases 0.004 *E*. A variation of the concentration of the KCN solution from 0.2 to 0.05 N had no influence on the maximum effect of the oxidizing agent  $\text{K}_3\text{Fe}(\text{CN})_6$ . The sum of the influences of several oxidizing agents is less than the maximum of the strongest of them. Addition of  $\text{NaCl}$ ,  $\text{CuCl}_2$ ,  $\text{Hg}(\text{CN})_2$ , and  $\text{CoCl}_2$  has either no influence on the velocity or retards it.

FROM time to time new minerals are being discovered, and although they may be at first hidden away in the collections of chemists and geochemists who are working along geologic lines, the time may come when their economic value may be recognized and they will find place in the industries of the world. Most of these minerals as discovered or determined by the geochemists are of only scientific interest and appear to have no relation to the arts and manufactures. But no one can determine when the mineralogic curiosity may prove to be a revolutionary factor in some industry. For instance, vanadium once belonged in this group, yet today its use in the manufacture of steel is increasing rapidly because it imparts to

the steel ability to withstand stress and strain and lessens 'fatigue.' Tungsten, too, was well known for 100 years, but only recently was it found that this mineral could be made into an electric-lamp filament which yields a light that is stated to be the nearest approach to daylight. The properties of minerals already known and of those newly discovered are constantly being determined by the mineralogist, whose province it is to work out his scientific problems irrespective of any application that the industrialist or the technologist may evolve from his conclusions.

### Mount Morgan Turbo-Blower Plant

The new turbo-blower plant at the Mount Morgan Copper Reduction Works comprises four furnace turbo-blowers and three converter turbo-blowers, electrically driven. Each of the furnace blowers is capable of compressing 18,000 to 20,000 cu. ft. of free air per minute to 64 oz. per square inch pressure. Each is driven by a 500-volt, direct-current, variable speed, electric motor, the speed varying from 2200 to 2700 r.p.m. The three converter blowers each have a capacity of 5000 cu. ft. of free air per minute to 12 lb. per square inch pressure, the speed varying from 2700 to 3050 revolutions per minute.

The blowers are all C. A. Parsons & Co. latest multiple-stage centrifugal type. The air is drawn from a chamber under the floor, which is connected to a tower, the inlet to which is about 30 ft. from the ground, in order to secure freedom from dust. The delivery from the machines is beneath, each machine being connected by means of a branch and valve to a main blast pipe. There is, therefore, no obstruction on top of the machines. An overhead hand-operated crane enables the various parts to be handled with a minimum of labor.

The main switchboard is placed parallel with the row of machines. Each machine is served by a starting panel equipped with overload and no-load circuit-breaker, special interlocked rheostat, field rheostat, and ammeter. The field rheostat, together with ammeter and pressure gauge, enables the machines to be run exactly in step. The main bay of the power-house is 114 ft. long by 32 ft. wide, with a side aisle, 10 ft. wide for the whole length. An overhead crane spans the main bay, and the switchboards occupy the side aisle.

The floor is of reinforced concrete, built 8 ft. above the ground level. The space in the basement beneath the floor is divided into two compartments, one being the suction chamber for the blowers, the other is utilized for the electric cable suspension and as a store-room for electric supplies. A portion of the floor at the eastern end is at the ground level, enabling material to be brought in by tramway under the overhead crane. The walls up to the floor level are of reinforced concrete, and above that level of timber framework lined with tarred galvanized iron, the roof being of the same materials.—*Queensland Government Mining Journal*.

### The Iron Industry of Tennessee

From the best information that can be obtained, the first iron mined in Wayne or Lawrence county, Tennessee, was in 1832. H. P. Seavy, of Iron City, is authority for the statement that what is known as the VanLeer mine was opened by Sam VanLeer and worked by him from 1832 to 1837. This mine was on top of the ridge a mile and a half west of the present site of Iron City. The old pits from which the ore was taken are scattered over probably more than 100 acres, and are yet plainly to be seen. They were worked by slave labor and the ore was hauled by wagon to a small charcoal furnace situated some five miles distant on Butler creek. Only the large lumps that could be sorted from the clay by hand were used, no attempt having been made to wash out the 'shot ore.' The pig iron was shipped down the Tennessee river to the Ohio, thence to New Orleans, and from there to Baltimore.

Standard Screens for Grading Analyses

By H. STADLER

\*After full and careful consideration and after ascertaining the views of kindred societies and of a large number of authorities in various parts of the world, the Institution of Mining and Metallurgy adopted, in November 1907, a series of specially manufactured standard laboratory screens for the purpose of bringing about unification in the measurement of screen products. In order to meet metallurgical requirements it was necessary to put a large number of screens at the disposal of metallurgists, but as in ordinary practice only a comparatively small number of screens is required, it is suggested, with a view to securing still greater uniformity, that engineers and metallurgists, in making a choice, should preferably adopt the screens specified in the annexed table. The selection of the screens of the restricted set here recommended has been made in such a way that the apertures are in agreement with, or very close to, those of the mathematically correct reduction scale, so that the series of the products of these screens will show a regular reduction in volume, or weight, of 1:4 from grade to grade.

The diameter of wire of the Institution of Mining and Metallurgy standards is equal to, or very closely approaches that of the clear mesh aperture. The area of discharge is therefore fairly constant for all screens. The 50 and 80 I.M.M. mesh have the same mesh apertures as the 60 and 90-mesh screens, respectively, already in common use on the Rand. As the difficulties attending the manufacture of the 200 I.M.M. mesh have not yet been overcome, and as the commercial so-called 200-mesh screens are very unreliable, and in fact not much finer than the 120 I.M.M. mesh, it is more advisable to drop for the time being the 200-mesh altogether and to rely on classification for grades beyond the 120 I.M.M., which with an aperture of 0.0042 in. marks actually the limit of accuracy for screen measurements. When screens are described simply by the mesh number it will be understood that the I.M.M. standard is referred to. In reporting grading tests it is desirable to state whether wet or dry screening has been employed.

\*Abstract from the *South African Mining Journal*.

Operating a Stationary Filter

By H. G. SMITH

At the Concheño mill of the Concheño Mining Co. a standard 30-leaf semi-gravity type Butters filter is in use. The operation of this required a longer solution wash than the crushing plant permitted, and trouble was occasioned by the cracking of the cakes during the transfer of charges, which made an even wash impossible. In the ordinary cycle of operations 15 minutes was consumed in pumping the excess charge, and about the same time was required to fill the filter-box again; thus the cakes were exposed to the air about 30 minutes, during which time large cracks were formed, and filtration practically came to a standstill.

To prevent the cracking of the cakes and at the same time to devote the 30 minutes time to useful account, I hit upon the following expedient. Instead of pumping back the excess charge of slime, and filling the filter with wash solution from the bottom of the tank, I connected the solution-line with a 4-in. pipe and valve, and to it a 4-in. pipe, perforated with 3/4-in. holes with 2-in. centres, which rested on the filter leaves and extended the length of the box. Then, after the formation of cake on starting the pump, I ran in the solution wash through the perforated pipe at the top of the charge, keeping the leaves covered all the time. In this way the 30 minutes consumed in filling and emptying the filter-box is utilized in cake-making and washing, and the leaves being submerged the cake has no chance to crack, an even wash is assured, and an additional 30 minutes wash is possible, or the cycle can be shortened to that extent.

Of course there is some mixture of slime and solution, but not as much as might be supposed. By watching the discharge of the pump the change can be detected almost instantly when the slime charge ends and the mixture of charge and solution comes in. Then the mixed part is turned to another tank, and pumping continued until the solution runs clear; when the pump is stopped until time to change the charge. The mixed slime and solution is allowed to settle, and the thickened slime is run to the agitators again, while the clear solution is turned to the mill solution or to the zinc-boxes. Possibly more solution is precipitated than would otherwise be the case, though not necessarily, as the dilute pulp can be run to the settlers, or thickeners, and the overflow of solution can be handled by passing to the zinc-boxes or run into the circulating mill-solution. More solution is handled and more power is consumed than ordinarily, but in any case there is always a certain amount of mixed slime and solution to be taken care of under any conditions.

In some cases it might be of advantage to carry the method a step further and replace the solution wash by the water wash; this could be done by having the sump tanks graduated so a definite amount of solution could be pumped and the stock of solution could be kept constant. This might be of advantage where the solution wash is very weak (as in some gold plants) where the mixed portion (which would have to be run to waste) could be kept at a low cyanide content. I offer this method to my co-workers for what it is worth; and while the application is original with me, I make no claim other than that by using the system the cracking of the cake is avoided (assuring an even wash) and that the time saved in the cycle over the ordinary method more than offsets the objection of the extra pumping solutions. Where a saving in the cycle of operations of 30 minutes can be made another charge can be run through the filter in the course of 24 hours time, which is quite an object where the filter is crowded to keep up with the crushing department.

THERE does not seem to be any immediate likelihood that the engineers of the Central Mining Corporation will rejoin the Mines Trials Committee, according to the *South African Mining Journal*; and it is possible that if they do not do so by next year, the organization may dissolve.

## Railroad Valley Potash Fields

By G. L. SHELDON

Railroad valley is in northeastern Nye county, Nevada, and Potash Camp, where the Railroad Valley Saline Co. is drilling, is 72 miles southwest of Ely, Nevada, and 125 miles northeast of Tonopah. The valley is from 10 to 20 miles wide, east and west, and over 100 miles north and south. At the north end, over a low divide, White Pine valley continues for 40 miles farther. At the south end, over a low watershed, Kawich and Penoyer valleys extend for 20 to 25 miles. The valley is bounded on the east by the White Pine range, 200 miles long, with an elevation of 8000 to 10,000 ft. On the west the Pancake and Reveille ranges form the near boundary, with an open drainage from Hot Creek and Reveille valleys into Railroad valley. These two valleys are bounded on the west by the Hot Creek range, which is broken by Hot Creek canyon, affording drainage from Fish Spring valley. Pancake and Reveille ranges have a general elevation of 6000 to 7000 ft. excepting isolated peaks. Hot Creek mountains have an elevation of 8000 to 9000 ft. The Kawich mountains, to the south, are an extension of the Reveille range, with an elevation of 7500 to 9000 ft., which constitutes the western boundary of Reveille valley. The Belted range, the southern boundary of Kawich and Penoyer valleys, is 25 miles farther south, with an elevation of 7000 to 8000 ft. The divide between Railroad valley and Penoyer and Kawich valleys is 6200 ft. The present old lake bed of Railroad valley has an elevation of 4700 ft., with a maximum length north and south of 15 miles and a width of 6 miles. The area of the present drainage basin into the old lake bed is 6000 square miles. The topography is such that a heavy rainfall on any of these valleys or mountain slopes must drain into this old lake bed, which has never had an outlet. It is a matter of record since the earliest settlement in 1865, that rare floodwaters, from all parts of the present drainage basin, have been seen to flow into the old lake bed. It is reasonably certain at some earlier time Kawich, Penoyer, and Little Smoky valleys all drained into Railroad valley. Of the exposed strata within the drainage basin, 85% is eruptive, or water-laid formation derived from eruptives, mostly rhyolitic and granitic rocks, which usually contain 3½ to 8% potash. Detailed descriptions of the formations are given in U. S. Geol. Surv. Bull. No. 208, pp. 61-68, 84-49, 161-164, 181-184, and Bull. No. 308, pp. 96-140. From the beginning of the Pliocene age to the present the erosion has been hundreds of feet, filling the valleys to their present condition. Of the enormous amount of material eroded and carried into Railroad valley, probably 4% was potash, in insoluble form in feldspars and micas. Part of this was decomposed into soluble salts that went into solution and later evaporated in Railroad valley.

The average amount of potash contained in the waters of the alkaline and salt lakes of the Great Basin, according to U. S. G. S. Bull. 330, is 0.29 part in 1000 parts of water. Reduced to tons of chloride of potash per cubic mile of water, this is approximately two million tons. Searles lake, California, contains about one cubic mile of water and is estimated to contain 10½ million tons of chloride of potash. In various parts of the valley there are lake bed terraces from 50 to 1500 ft. above the present lake bed. The lowest is at the north end, where an old shore line of sand and fine gravel reaches across the valley except where cut out by recent floodwaters, and is utilized as the crossing of the proposed Ely, Tonopah & Goldfield railroad.

Toward the north end of the old lake bed surface deposits of salt occur the incrustations being ¼ to 3 in. thick, and are composed of soda, magnesia, borax, and 5 to 20% of potash. The water, which is generally found in the discovery holes of the placer claims, contains 4 to 15% potash; even the surface soil of the lake bed shows

1 to 5% potash. Thirty years ago the management of the Tybo mines (45 miles distant) gathered a lot of this surface salt for use in the chlorination of silver ores, but it contained so much potash that it could not be used.

The potash content attracted the attention of the management of the Railroad Valley Saline Co., and after much time in examinations operations were commenced. The valley has been examined by several of the engineers, geologists, and chemists of the Survey and Department of Agriculture, and hundreds of samples have been taken from various parts of the valley and analyzed. The Railroad Valley Saline Co., in financing its operations, has made only a plain statement of the facts, as it is practically a gamble until potash is found in workable quantity. The drill-hole reached 1200 ft. by reducing the casing from 9½ in. to 7½, then to 5½, and finally to 4½ in., using a Keystone drill. Experience has shown that this is not heavy enough, and a standard 4000-ft. rig such as is used for oil wells has been purchased.

Much trouble has been experienced with quicksand and artesian water-flows. The first artesian water in notable amount was at 285 ft., after driving the 9½-in. casing to 305 ft. It was reduced to 7½ in., and the continuous flow of good water has afforded an ample supply for operations. The quicksand rose as high as 275 ft. in the casing; probably every foot below the 200-ft. level has been re-drilled a dozen times. Three-quarters of the depth of the hole is in sand, though layers of clay a few feet in thickness were cut. Only one was of any thickness, 50 ft., between 500 and 600 ft. in depth. There were many flows of artesian water, which were shut off with the casing. Except at one place, where the water carried some sulphur, it has invariably been fresh and not more than a trace of potash has been found.

The superintendent, D. H. Walker, has made tests every 3 to 5 ft., and a part of each sample has been sent to the United States laboratory at the Mackay School of Mines at Reno, Nevada, as a check. The fact that all of the water from the well has so far been fresh encourages the belief that in depth, below some thick impervious clay bed, potash in commercial quantity will be found. As there has never been an outlet to the valley, it is expected that the potash will be found in soluble form. This will conduce to cheap operating costs. The Railroad Valley Saline Co. has recently reorganized and increased its capital stock to 1,000,000 shares of \$1 each, and has placed 600,000 shares in the treasury. It has recently bonded all of the ranches and water rights on the Duck Water creek, in the north end of the valley, and has segregated 57,000 acres of Government land under the Carey act. A dam will be built at a natural reservoir site on Duck Water creek, affording a large amount of electric power. The water will then be used for irrigation, it being the intention to supply the Government land with artesian water by drilling wells. Of the proposed irrigation and water-power enterprise, more than three-quarters is included in the property of the Railroad Valley Saline Co. It is the intention to drill several wells in various parts of the old lake bed for potash. As there are no deep wells in any of the basins of the arid basin country, the present development is pioneer work. Part of the year some places in the lake bed are very soft, and this has necessitated the building of several miles of roads. By the efforts and financial assistance of the company, both Nye and White Pine counties have very materially improved their roads, one of which is now used as an interstate automobile road between Salt Lake, Ely, Tonopah, Goldfield, and Los Angeles. With the exception of an occasional jack-rabbit, horned toad, or mouse, animal life is entirely absent in the old lake bed. On the northern portion there is some thin salt grass, rushes, and small greasewood. A part of the lake bed has many sand-dunes, in some places from 3 to 6 ft. high, and in others 10 to 30 ft. high. The dunes are peculiar in that they do not shift. Snow and rain appear to cement the sand, forming a hard crust.

In places a team can be driven over it, and in other places there are occasional holes a few inches in diameter containing water and mud with no bottom. There are other places where the surface soil is soft and the shoe sinks in 2 to 8 inches in walking. This is called 'self-rising' ground and caused by soda, it is said.

About four or five miles south of the present drill-hole is a perfectly level lake bed which evidently has water at times over its surface, but in the summer is hard and smooth, so that it is possible to drive over it. The sandstorms here are simply 'fierce'; it is impossible to see, even with goggles on, so that it is easy to get lost. The discovery holes, 10 by 6 by 4 ft., sometimes fill up in one week. The pencil marks on the corner stakes of the claims on the south side cut away in a few days, the sand acting like a sand-blast. For much of the foregoing data I am indebted to the kindness of D. H. Walker.

## Diamond-Fields of Pretoria

The increased activity in prospecting operations in the Pretoria diamond-field as a result of the better outlook for diamond mining, has brought to more prominent notice a somewhat peculiar igneous deposit about twelve miles west of the Premier mine, and eight miles northeast of Pretoria, on a farm known as Derdepoort. This deposit is described by the Transvaal Geological Survey as a 'volcanic breccia,' a better description not yet having been found. It appears to represent a volcanic mud flow in one of its numerous early stages, of which true kimberlite may be said to be one. This volcanic breccia is about a mile across, and while it presents many features in common with 'blue producing diamond ground,' some of the essential mineral accessories are absent and foreign elements are present, among them hornblende. The most important discovery claimed, however, is that the volcanic breccia contains diamonds, but to what extent has not yet been proved. This display of reticence to prove its true value tends to cast doubt upon the real value of the find. There was a time when the value of a diamond-bearing deposit was judged entirely by its likeness to that at Kimberley, not only in constituents but in the geological age of the surrounding rocks. Since that time, however, many of these diamond-bearing ground illusions have been dispelled, and it is recognized that a true diamond pipe can exist in any description of rock, igneous or otherwise, and containing minerals not yet recognized or found at Kimberley. There does not seem any sound geological reason why this volcanic breccia should not be related to and formed in exactly the same manner as the blue ground forming the volcanic diamond-bearing pipe at the neighboring Premier mine. The deposit or mud flow may be of a somewhat different age, but as long as it is amenable to the usual method of treatment and carries enough diamonds of adequate quality to make mining operations profitable, its precise method of origin or geological status is only of academic interest. The hesitancy displayed by the owners to fix by actual tests on an adequate scale the true diamond yield of this volcanic breccia only tends to confirm the views, so frequently expressed, that the discovery is of little or no economic value.

THE present plant at the Busstick mine consists of 20 stamps and three tube-mills, and is being enlarged by adding four Nissen stamps and one Krupp tube-mill. These additions will increase its capacity from 6000 to 10,000 tons per month. During its past financial year the Camperdown claim of the Wanderer mine produced 125,766 tons of ore, which were dry crushed by rolls and cyanided. The total profit was only \$39,500. During June the yield was valued at \$37,500 and expenses \$31,500. Ore reserves are stated to be 350,000 tons in the five properties, and as 220,000 tons is mined yearly, this tonnage should keep the mill working for 18 months. Noel Griffin is now in charge.

## Profits in Lead Smelting

By LUCIUS L. WITTICH

Lead smelters handling ores from the Joplin district buy their galena at a rate of \$62 per ton, upon an assay of 80% metallic lead, and convert it into metal which sells for \$76.38 on the East St. Louis market, their margin being \$14.38 for every ton of galena treated. This margin is unusually great and means an enormous profit to the smelter. As a result, the demand for galena is strong, but prices are not strong enough to warrant an unusually heavy production. The figures given above are the highest prices quoted, both for metal and ore. The former ranges down to \$5 per hundredweight, whereas the top price of \$5.025 per hundredweight is used. Ore, on the other hand, ranges down to \$60, whereas the \$62 quotation is used. Thus, if there is any discrepancy in the above figures it is slightly in favor of the smelter, and the margin quoted should be even greater than it is. In the year of record galena prices, 1907, when the top price went to \$88.50, lead was quoted at \$6.35 per hundredweight, which meant

A LARGE PILE OF LEAD CONCENTRATE.

a margin of \$10.02. In October 1911, lead smelters produced pig lead at a margin of \$7.42.

The lead ore from the Joplin district is regarded as the purest mined in the United States, its average metallic content being placed at 80%. When pure, galena contains 86.6% Pb and 13.4% S. (H. O. Hofman places the average metallic content of the Granby, Missouri, product at 84%.) However, in selling lead on an 80% metallic basis is recognized, and if the ore carries more than this amount the smelters pay extra for it at the rate of \$1 per unit, and in return, of course, derive a larger percentage of metallic lead. The Joplin product also carries on an average of 1.25 oz. silver per ton, but no effort is made to recover this. As the average metallic content in galena is 80%, a ton of ore carries 1600 lb. of metal, and of this approximately 95% is recovered at the smelter. Thus a ton of ore produces 1520 lb. of pig lead, which, at present prices, sells for \$76.38, or \$14.38 more than the ore cost.

When ore sells on a \$62 basis a heavy tonnage of galena can be mined at a profit. Many of the outlying producers of the district figure conspicuously in the production of galena mined from shallow levels. Much of this ore is free 'chunk lead,' requiring only the removal of the adherent clay by washing or hand cobbing to make it ready for the market. Hand-jigs are in common use at lead mines where the galena occurs in fine particles. At other places concentrating plants are employed, but few mines are worked solely because of the presence of lead. Zincblende is the chief product at the majority of the milling properties and the recovery of the galena from the first cell of the jigs often represents a source of clear profit. However, the production of lead ore could be increased ma-

terially. The entire central district, including districts in Missouri, Kansas, and Oklahoma, is now producing about 960 tons of galena per week. This could be increased by several hundred tons, at a conservative estimate, if ore prices were high enough to warrant the working of much thin galena-bearing ground, but such an increase can hardly be expected at present prices.

Much of the lead produced in this district is treated at local smelters. A large plant is in operation by the Picher Lead Co. at Joplin. Here both pig lead and white lead are produced. The same company has the controlling interest in the Webb City Smelting Co. The Granby company operated a smelter at Granby, Missouri, but fire destroyed this plant recently. It may be rebuilt. At several points in the Kansas natural-gas zone, lead ore is smelted. Webb City, Missouri, holds first place in the weekly production of galena, the output averaging 450 tons; Joplin comes second with an output of about 125 tons; while Miami, Oklahoma, is a close third with about 100 tons, and its present rate of increase bids fair to surpass Joplin in the near future.

## The Lead Market

Owing to the car shortage and the probability that this shortage will be more acute as the season advances, shipments of lead are being delayed all along the line. The continuation of the Utah strike is also likely to affect the Utah lead smelters before long. Stocks of lead in the hands of producers as well as consumers are lower than for many years. In view of these conditions, L. Vogelstein & Co. warn consumers not to be deceived by the recent advance in prices into the belief that favorable conditions have been fully discounted and that the American Smelting & Refining Co. will be ready to aid consumers at lower prices whenever they are in need of metal. Lead is the only metal which is still cheap, and the price, therefore, cannot be affected by the presidential election or the possibility of tariff changes. The European price of lead has never been as high as at present, while the American price has time and again reached a level of more than 1c. per pound above present prices.

While large new sources of supply of other metals, notably copper and zinc, have been discovered during the past few years, nothing worth mentioning has been added to the lead supplies of the world. In fact, the rich mines of the Coeur d'Alene and the enormous deposits at Broken Hill in Australia have been gouged of their richest ore. The only increase in production in this country has come in recent years from the old mines in Missouri, where, however, decreasing percentage of metal contents in the ore is also a warning that the limit has been reached. There is no reason why the American Smelting & Refining Co. should continue to supply consumers with lead at low prices as they have been doing during the past few years of depression. Outside producers have sold their product for months ahead; there are no stocks; speculators do not exist. Business in white lead and material for paints is excellent. The consumption of lead-covered cables is larger than ever before, and consumers are cautioned against the danger of a squeeze which might be produced by a sudden awakening of the demand in this country—a demand which can only be supplied to a limited extent by the American Smelting & Refining Co. Consumers should not fail to recognize the importance of carrying at least a month's supply of lead, even though the price has advanced and is probably 10% higher than during the average of the past few years of depression.

ANNOUNCEMENT is made by the Civil Service Commission of an examination to be held shortly to fill a vacancy in the position of mineral technologist with the Bureau of Mines at Denver, Colorado, at a salary of \$3000 per year. The subjects upon which rating will be made are: general education and technical training, 30 points; experience in connection with the rare minerals, and fitness, 40

points; publications or technical or professional reports, 30 points. The examination is open to citizens of the United States who are between the ages of 25 and 40. A similar examination will be held to fill the position of mine sanitary engineer in the field service of the Bureau of Mines at a salary of from \$1800 to \$2400 per year.

## Unwatering the Plymouth Shaft

The Pacific shaft of the Plymouth Consolidated mine is vertical and 1650 ft. deep. The workings connecting with it had been filled with water since June 1892 until reopening was commenced this year. The method used was that of bailing with 500-gal. skips, operated by an electrically driven geared hoist. A sinking pump having a capacity of 100 gal. per minute was used in emergencies only. It was used from the surface to a depth of about 200 ft. during the first months of operation, pending the completion of the hoisting plant. The operation of the latter was commenced on March 7, 1912, and the unwatering was completed on October 1.

It was estimated from the incomplete data available that approximately one million tons of material occupying 12,000,000 cu. ft. of space had been excavated from the workings to be unwatered, and it was estimated that one-half of this space, namely, 6,000,000 cu. ft. would be found to be filled with water. In round numbers, this would amount to 48,000,000 gal., in addition to the current flow during the period of unwatering, which was estimated at 720,000 gal. per month. The amount of water actually removed was 43,663,000 gal., and assuming that the figures for current flow are approximately correct, about 5,000,000 gal. would be accounted for from this source, leaving 38,663,000 gal. as the actual content of the mine workings.

The shaft timbers were generally found to be in good condition, and in repairing the shaft from the surface to the bottom there were used only 45 complete shaft sets and 11 single-compartment sets. The principal cost of repairs was due to the labor required in cutting out and removing old shaft ladders, compressed air and ventilating pipes, and replacing them with new ones. Aside from equipment, which was expensive, the cost of unwatering and repairing the shaft, exclusive of administration, was about \$15,000, nearly equally divided between taking out the water and the shaft repairs.

The shaft was, of course, always slippery, slimy, and full of falling water, and at times the air was so bad that men could work in the bottom only a half-hour at a time, and yet the entire operation was conducted with an injury to only one employee, who was incapacitated for work for one week only. This reflects great credit on the care and attention of James F. Parks, the superintendent.

## September Copper Review

By MISHA E. APPELBAUM

The copper market during September exhibited practically the same tendencies as during the past few months, excepting that Europe made more liberal purchases. The statistics for September again show a large production for the month, but, contrary to expectations, there was an increase in the visible supply of about 16,000,000 lb., which is nearly all accounted for by the fact that domestic deliveries fell off some 15,000,000 lb. I consider the let-up in the domestic deliveries as temporary, and believe that the statements from now on will show some decreases. The business with the copper consumers in this country is excellent and Europe has still to buy large quantities of copper. The metal situation, therefore, seems to be in about as good a statistical position as the producers could wish, but they are to be heartily commended in selling as much copper as possible at 17 $\frac{3}{4}$ c., although they were several times in position to quickly advance the market considerably higher.

## Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

### Sticking to the Job

The Editor:

Sir—Every one gives advice to the young engineer. I (a young engineer) refuse to take seriously any more of

### Step-Bearing for Slime Agitator

The Editor:

Sir—I have had my attention called to an article in your issue of September 21, 1912, entitled 'Step-Bearing for Slime Agitator,' by Douglas Waterman, in which he describes one of our most valuable inventions, patented by the L. C. Trent Engineering Co., Inc., in the United States letters patent No. 937,974, October 26, 1909, as well as in a number of other foreign countries. Mr. Waterman, at the end of his article, states, "It only remains to add that

this device is not patented, and can be turned out by any foundry at small expense."

This is a remarkable statement for Mr. Waterman to make because the article, precisely as described by Mr. Waterman, certainly is patented in the United States and abroad.

L. C. TRENT.

Los Angeles, October 1.

### Water as an Indication of Ore

The Editor:

Sir—On this topic, G. E. Collins says, "a dry dusty condition in the bottom of deep mines often seems to coincide with a lessened amount of quartz in the gangue; and a vein-filling consisting of clay and crushed 'country'." The average percentage of silica in the Kalgoorlie group of mines is about 65%, up to 75% in the Great Boulder mine, and there is an increase of silica with depth, also with dry and dusty conditions. At the Waihi mine, in New Zealand, where 727,000,000 gal. of water is pumped yearly, there is 96% of silica in the ore down to 400-ft. depth, while from 400 to 850 ft. there is only 91%. But still, water is there looked upon as a good indication of ore.

M. W. VON BERNEWITZ.

San Francisco, October 5.

DET NORSKE NITRIAKTIESELSKAB, with \$2,700,000 fully subscribed capital, has been formed in Christiania to produce sulphate of ammonia from the atmosphere, after the method of an Austrian engineer, Dr. Serpek, according to a consular report. The invention has been developed by a French company, Société Generales des Nitrures, and the patent right for Norway has been acquired by Det Norske Aktieselskab for Elektrokemisk Industri. The new company has been started jointly by French and Norwegian interests. Construction of the plant will commence immediately at Arendal, operations to start in the autumn of 1914.

## Special Correspondence

### NEW YORK

THE COPPER SITUATION.—PRODUCERS AND DIVIDENDS.—THE TRINITY JOKEBOOK.

The October statement of the Copper Producers' Association, while not greatly affecting the share market, was not without considerable significance. Surplus refinery stocks were found to have increased during September some 16,300,000 lb. The consumers and those of the public who have persistently maintained a skeptical attitude regarding the disappearance of the copper surplus have not been slow to point to the reported sales of copper metal, the shut-down at Bingham and at Ely, and the unexpected increase in stocks as a justification of their position, in which many of them have been somewhat stubborn. While there was a slight falling off in both export and domestic deliveries as compared with the average for the preceding eight months, deliveries for September were not far below normal figures. Domestic deliveries were in round numbers 63,000,000 lb., which, while 15,000,000 lb. below the high record of August, is still only 5,000,000 lb. below the average for the year, and the year's figures have so far broken all previous records. There was a decrease in exports of 10,000,000 lb., but exports were but 4,000,000 lb. under the monthly average for the year. Production was, in round numbers, 140,000,000 lb., which has been exceeded but once—in August—when all records were broken with an output of 145,628,521 lb. Copper producers are saying that they are greatly pleased with the statement, as it will make it unnecessary to adopt any extreme measures to avoid a 'runaway market.' The consumer has heard about the impending 'runaway market' until, in a measure, it has ceased to frighten him. The price to which the market has been manipulated has greatly stimulated production, and the real question now is the ability of those in control of the situation to maintain a balance. The big new low-cost copers, with all or nearly all of their productive life ahead, must and will make hay while the sun shines. Shut-downs of these larger properties are almost out of the question because of the tremendous expense which at once begins to pile up. The Bingham strike has already cost a loss of \$2,000,000, to say nothing of the extra expense incurred.

The manipulation which withdrew the threatening surplus, at least from public view, and the financial strength of the factors which assumed control, and still have control, of the copper situation are elements which, for a time, have overshadowed the new copper which must find a market. The consumption abroad has been at an unheard-of rate, and a reaction is admittedly long over-due. At home conditions are not such as to justify too great confidence in the immediate future; to use the language of the street, everybody seems to be advising bull tactics for the other fellow and practising a great deal of caution for himself. From this it may be fairly argued that the next few months are more likely to see production at an abnormally high figure than consumers scrambling for metal. It will be strange if the copper surplus does not grow steadily during the next quarter. However, the financial strength of the copper group is without limit. It is one of the largest manipulations ever attempted, and if money is required to save the situation it will be forthcoming in amounts never dreamed of by any of the syndicates that have heretofore, from time to time, attempted to control the copper market. Nor in any of the past manipulations was there ever such unity of the sellers or handlers of the metal and the mining companies. In the present situation these are largely identical. The strength of the consumer, or rather the main dependence of the consumer, lies in the fact that curtailment is next to impossible. Present-day mining operations are on a scale where profit is won by the handling of tremendous tonnages only, and the 'porphyries' must keep going in any event.

The strike at Bingham and at Ely is reported to be

wearing itself out, happily a spirit of compromise seems to have prevailed and by concessions on both sides an early agreement and resumption of work is expected. One important result of the strike at Bingham was the closing of the smelter at Tooele, all of the copper furnaces being shut down. Some properties that were shipping custom ores to Tooele have also temporarily ceased operations. Among these, the South Utah, which had a small strike of its own on hand at the same time and was experiencing trouble with water in the lower levels, has stopped production for the time being.

So far as the share market is concerned all the ammunition consists of dividends. Amalgamated is to be put on a 6% basis, and the stock to be sold at par; this is to be heard around nearly every ticker where bulls and bears congregate. Utah Consolidated is to pay one more dividend this year if the labor troubles at Bingham are settled within a short time, as expected. Greene Consolidated has declared a dividend of 40c. per share, which goes almost entirely into the Greene-Cananea treasury, and will be thence distributed to shareholders by a dividend of 25c. per share, payable November 30. This payment will make 75c. per share paid this year by the Greene-Cananea. Chino is expected to announce a dividend date very shortly and to make an initial distribution either late this year or early in 1913. Chino is earning at the rate of about \$6 per share per annum and producing copper at the rate of 42,000,000 lb. per year. Nevada Consolidated and Utah were confidently expected to make an increase in the next quarter in the rate of payment to shareholders, but probably this will be postponed for at least one quarter, owing to the expense entailed by the strike.

The reading public has always paid to Thomas W. Lawson the tribute of reading with intent interest the various products of his pen. Lawson was the individual who first stirred to action the forces of revolt against the old financial regime in New York and Boston. As a phrase-maker, a user of originally compounded adjectival descriptions, bizarre, but forceful, and on a level with his public instead of above its head, he is unique, illuminating, and instructive. But not all of Lawson's ability is given to the letting of the light into dark places. He can obscure when need be and make phrases which neither commit the writer nor enlighten the reader. A recent report just mailed to the stockholders of the Trinity Copper Co. says in part: "The only thing of interest to stockholders in A. H. Brown's report is that the Trinity mines, with equipment of buildings and machinery, are under constant care and repair by intelligent caretakers, and are ready to resume operations upon short notice; all legal matters are attended to and competent annual assessment work performed upon any and all of the possessory locations; the property is in good condition and the ores as great an asset as in former years." Surely after reading this summary, every Trinity stockholder would feel that he knew all about his ore reserves, their probable extent, net and gross value, the probable life of the mine, and so on. No one but Lawson could be expected to 'get away' with so good a joke.

John K. Erskine, Jr., has sold the old New England & Clifton Copper Co. property to the Detroit Copper Co., a Phelps-Dodge subsidiary. In the deal the Detroit Copper Co. acquired all of the New England properties and also control of the Standard Consolidated Copper Co., which owns a majority of the stock of the Standard Copper Mines, the Clifton Copper Mines, Ltd., and a 26% interest in the Coronado Mining Co. The Shannon Copper Co. is a large holder in the Coronado. New England & Clifton was largely floated abroad, and something more than \$2,000,000 was expended upon the properties, but financial trouble accumulated and the interests sold to the Detroit Copper Co. were acquired by Mr. Erskine at sheriff's sale over a year ago. The lands purchased by the Detroit company amount to about 1200 acres.

Prospectors and claim owners in British Columbia are interested in the movement of a group of English and American capitalists, some of whom have operated on the

Rand in South Africa, who are preparing to do some systematic exploratory work north and west of Edmonton. Assay offices are to be established, and if mining properties of sufficient merit can be developed, a smelting plant will be established at Tete Jaune Cache or in the Fort George district. Some samples brought in from the Fraser River district are said to justify careful prospecting.

There are a great many New York people interested in the properties at El Oro, Mexico, and these are concerned over the report that this mining district, one of the largest and most important in Mexico, is besieged by rebel forces. The plant of the American Smelting & Refining Co. at Anganueo, in Michoacan, is said to have been raided. The Batopilas and San Toy companies have been operating, however, and the trouble at one time said to be acute at Cananea has apparently been avoided. The general opinion seems to be that the rebel forces have degenerated into brigandage, mostly unorganized, and that wherever a leader desires to do so, he can rally a band of followers who loot and rob, dispersing when any force threatens them. Evidently Mexico's main need is a policeman with a heavy and active night-stick.

An echo of past history in copper was heard this week in the taking up for examination of the old copper properties at Bluehill, Maine, which were closed down when the Secretan syndicate collapsed in 1889. Engineers are going over the ground, and there is a possibility that the Douglas mine will be unwatered and re-opened. This particular property was unwatered in 1907, but the people interested were a little too late to get any benefit from the high prices that ruled just before the 1907 panic, and just about the time the unwatering was completed the drop in copper began and in consequence the work was abandoned.

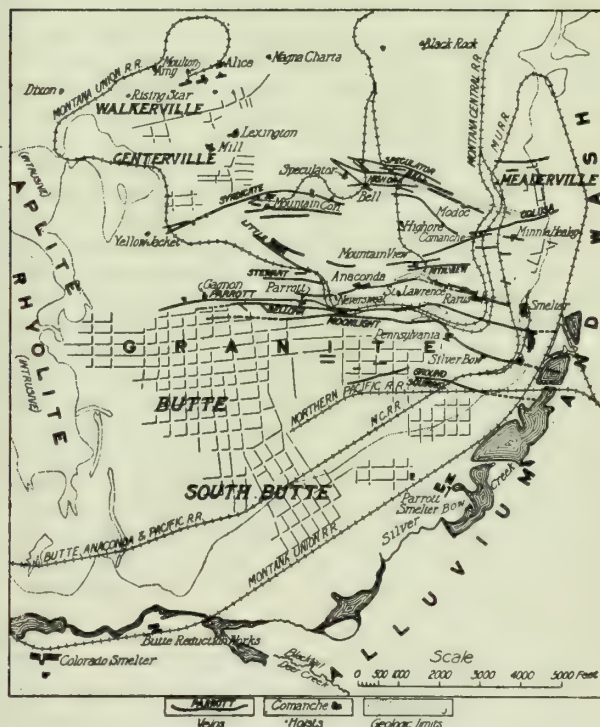

## BUTTE, MONTANA

LEACHING OF COPPER ORES.—NORTH BUTTE DISCOVERY.—  
AIR HOISTING AT BUTTE.

The proposed copper-leaching plant at the Bullwhacker mine calls attention to the activity in copper-leaching in other parts of the state. Frederick Laist, of the Anaconda smelter, has been experimenting for several years on a leaching method wherein the sulphuric acid consumed in dissolving the copper will be regenerated when the copper is precipitated by hydrogen sulphide. He prepares the hydrogen sulphide from an iron matte produced from auriferous pyrite. It is reported that his method has been perfected, and that a commercial plant to treat the concentrator sand tailing is soon to be erected at Anaconda. At Maxville, in Granite county, the Royal Mining & Milling Co. has a small leaching plant for treating silicious copper ores. John D. Fields, engineer for the company, claims that the extraction costs are about 4c. per pound of copper produced. The method is briefly as follows: After crushing the ore and leaching with sulphuric acid, the resulting copper sulphate solution is passed into precipitating cells 10 ft. long, containing 30 anodes of 12 sq. ft. each, and corresponding cathode surfaces. The copper is precipitated at the rate of 10 lb. per day on each cathode by a 3000-ampere current at 5 volts. A 90% leaching extraction is claimed. It is planned to treble the capacity of the plant.

The East Butte Copper Mining Co. has opened up a fine chalcocite and bornite orebody on its 1200-ft. level. It is said to average 10% copper. This find is stimulating activity in surrounding properties. To the east on the Tropic claim, the Anaconda company is sinking a shaft, and one is proposed for the Atlantic claim farther north. Adjoining the East Butte company's property on the east, A. B. Wolvin and associates are doing some work on the Brundy property; the Montgomery claim showing up silicious oxidized ores like that in the Bullwhacker property. It is rumored that the Butte & London Copper Development Co. is to be rehabilitated under the supervision of Duluth capital, and that the present 1100-ft. shaft is to be continued 500 ft. deeper.

The North Butte Copper Mining Co. has made another important discovery, this time in the north cross-cut of the 2800-ft. level. Ten feet of average 5% ore was found in what is thought to be either the Jessie vein or Gem vein. This discovery is cited by some as proof that there is a lean zone in the Butte district at about the 2000-ft. level, followed by a richer zone below. The facts, however, are that the ore-shoots are limited vertically as well as horizontally, lying in the plane of the vein as lenses, like plums in a pudding. This new discovery appears to be a plum that did not extend as high as the 2000-ft. level. The Great Northern railway, which transports the Butte ores to the Great Falls smelter, was tied up last week by the caving of a tunnel between Butte and Helena. A temporary track has been constructed around the mountain until the tunnel is repaired. Before the completion of the

THE BUTTE DISTRICT, MONTANA.

temporary track, ore trains for Great Falls were routed over the Northern Pacific railway tracks as far as Helena.

The Missouri river is fast becoming the principal factor in the power production for the Butte mines. The Original mine is the next one to be closed, pending the installation of an air-hoisting plant, connected with the electrically driven central compressor plants. After work at the Original is completed, the Badger State mine will be next in line for the new equipment, and within a year very few of the large hoisting plants in Butte will be using steam. The mines now fully equipped with air-hoisting plants are the Leonard, West Colusa, Tramway, Mountain View, Pennsylvania, High Ore, and Diamond. This utilization of water-power from the Missouri river at Great Falls for power purposes at Butte has been made possible by the perfection of long-distance high-voltage transmission lines. At present the current from Great Falls is sent to Butte under 100,000 volts, carried on wires very heavily insulated at the points of support. The judgments held by John P. Reins against the Reins Copper Co. have been assigned to C. F. Kelley, managing director of the Anaconda Copper Mining Co. From this, it would appear that the latter company will take over the Reins property. It will be a simple matter to develop it from the adjacent workings in the Leonard mine. The new 30 by 72-in. hoisting engine for the Black Rock mine of the Butte & Superior Copper Co. is now being installed. The new engine can handle the 7-ton skips to a depth of 3000 ft. A large new head-frame and skip-changing device are also being erected.

Experiments are still under way regarding the machinery for the new Clark concentrator. That the plant is to be erected is now beyond question, as grading on the site north of Timbered Butte is under way, and heavy railway rails are replacing the light street railway tracks on the Montana street line south of the railway tracks. The heavy track will be extended to the new plant so that locomotives can deliver the carloads of machinery to the plant without transfer.

### LONDON

CORNISH MINING PROSPEROUS.—HUMBOLDT ROASTING FURNACE.—EXIT THE VANNING SHOVEL ASSAY.

Once more there is a prospect of a boom in Cornish tin mining. Perhaps I ought to say the symptoms of a boom, for the circumstances are such that it is next to impossible to create a furore about an ancient mining district, whatever the chances of profit are under improved metallurgical conditions and a period of high prices of the metal. It is of interest to record that such well known firms as Bewick, Moreing & Co., John Taylor & Sons, Bainbridge, Seymour & Co., and Merricks, Crane & Co., are all at the present time keenly interested in new projects in Cornwall. E. S. King, of Kalgoorlie fame, who has worked such a beneficent revolution at Carn Brea & Tincroft, is being besieged by hosts of capitalists and mine-owners with a view to securing his services as adviser in various reopening schemes. Arthur Richards, who has been the pioneer of re-treatment of old tailing dumps, is also in demand, and under his direction the old Killifreth mine, east of Redruth, is to be reopened. H. C. Hoover is having a shot at an old property between Penzance and Camborne, and during the last few months many other substantial American mining men have also been touring the Duchy and making a study of conditions. The scarcity of tin ore in other parts of the world is stimulating this interest in the old county, and it can hardly be doubted that its numerous tin lodes will still yield large amounts of metal.

The fortunes of the Wheal Jane mine, between Truro and Chacewater, are attracting attention once more, owing to the fact that this mine is the only one that is working tin ore containing much pyrite. After years of struggle the Falmouth Consolidated company, which reopened this property, is now getting its plant into working order, and hopes are high that, in spite of past large outlays of capital and a refractory ore, profits will be earned in the near future. The ore as sent to the stamps shows a content of 18 to 20 lb. of black tin per ton by the vanning-shovel assay. The first concentrate contains about 160 lb. per ton and 28% sulphur. This concentrate is dried and roasted in a Humboldt furnace, and the product passed through pulverizers for the purpose of freeing, as far as possible, the particles of black tin from the adhering friable oxide of iron without further comminution of the tin. The product is sent to another set of tables and buddles for the recovery of a clean tin concentrate. The Humboldt roaster is of interest, as it is designed to prevent attrition of the material roasted and of reducing the amount of fine material carried away by the gases. The furnace is of the multiple-hearth type with central vertical shaft carrying rotating rabblers. To prevent attrition the passages delivering the material from one floor to that below are made with a gentle slope; and for the purpose of preventing much dust being carried away different passages from one floor to another are used for the ascending gases from those used for the travel of the concentrate downward. The battery contains 60 stamps, weighing 1250 lb. each, crushing 3.5 to 4 tons per 24 hours. Only 40 are running at present, pending the completion of the third Humboldt furnace; in fact, it is not possible yet to roast the whole of the current output of the 40 stamps. The monthly tin sales do not, therefore, correspond with the tonnage milled. Absorption towers and condensers have been erected for the

prevention of the escape of the sulphurous gases. The arsenic is recovered in flues in the usual way.

But the most important factor in Cornish mining is the recognition that the vanning-shovel assay is the great stumbling-block to progress. The old Cornishmen, and most of the present managers and miners, have argued that this method of estimating the content of the ore was the best, as it indicated the amount of cassiterite that could be extracted by water concentration. This is now an exploded theory. The margin between content and recovery is far greater than was admitted. Not only is the extraction by water-concentration low, but the vanning-shovel assay on which the results are calculated shows considerably less tin than there actually is in the ore as shown by the chemical assay. The discrepancy between the content and recovery was forcibly emphasized by the announcement by Arthur Richards that at the Cornwall Tailings Co.'s plant it is impossible to extract more than 40% of the tin by water-concentration, while Merricks, Crane & Co. have more recently put it on record that, at Botallack, the standard Cornish dressing plant recovers no more than 50%. Mr. Richards also gives some startling figures as to the content of tailing discharged into the Red river. The introduction of the chemical assay has disclosed an even greater imperfection than the average critic of Cornish methods had expected. In tin, as with copper, engineers are engaged in experiments in connection with centrifugal separation and chemical extraction. Up to the present time cassiterite has proved unamenable to oil-flotation, though among those who have devoted attention to this subject there is a general belief that some modification will be discovered before long whereby the process may be adapted to tin.

### JOPLIN, MISSOURI

ZINC AND LEAD PRICES CONTINUE HIGH.—REOPENING OF SUNNY BROOK.—NATURAL GAS SUPPLY WANING.—NOTES OF THE MINES.

The heaviest shipments in the history of the Joplin district were made last month. Mention was made in the *Mining and Scientific Press* of September 21 of a shipment for the week ended September 7, valued at \$469,972. This was the greatest weekly shipment up to that time. For the week ended September 28 shipments reached a valuation of \$472,075, thus setting a new record. The weekly shipments seldom fall below \$400,000 in value, and if this rate continues, shipments during 1912 will amount to more than \$17,000,000 in value. The nearest approach to this was in 1907, when the aggregate valuation was slightly in excess of \$15,000,000. Prices for both zinc and lead are strong, the former bringing \$56 to \$64.50, assay basis of 60% metallic zinc, while choice lots command as high as \$67 per ton. Lead ore has reached \$68 to \$69 per ton, the highest since 1907, when it went to \$88.50. With the exception of the high price of 1907, 1906, and 1905, in each of which years the price touched \$80 or better, the present offering is the highest in the record of the district.

Repeated attempts have been made to mill the ore from the Sunny Brook tract, west of Joplin, at a profit, and operations have again been resumed. This is somewhat of an experiment, the ore being extremely low grade, the blende and galena content being less than 20%. Formerly the company was known as the Hackett Mining Co. Metzler and associates, of New York, now operate the property, and C. W. Landrum is superintendent, succeeding W. K. Hackett. The mill is unusual. Formerly it was equipped with the Richards pulsator jigs. These have been replaced with the ordinary jig used throughout the district. The mill has 600 tons per day capacity. Ore is now being hoisted from three shafts, two of which are on the west part of the tract, one being at the mill, the other a short distance west; both of these are in sheet ore at a depth of 190 ft. A new shaft, at the east of the tract and connected with the mill by a long tram-

way, is in soft ground at a depth of 140 ft. and shows thin ore.

The natural gas supply from the southern Kansas and northern Oklahoma fields is gradually waning. Pennsylvania stockholders of the Kansas Natural Gas Co., which supplies gas to the Joplin district, and to numerous cities and towns in Kansas and Missouri, have asked that receivers be appointed. They claim no dividends have been paid for three years. Local operators of the company claim the costs have been in excess of the income. The petition asking for the appointment of a receiver was filed in the Federal court at Kansas City, Kansas. As a result of the gas shortage, gas service has been ordered discontinued beneath boilers and in gas engines. It is to be conserved for domestic purposes only.

### SALT LAKE CITY, UTAH

ATTEMPTS TO REOPEN THE MINES.—WEAKENING POSITION OF THE FEDERATION.

The real struggle between the mine operators and the miners in Bingham is now on, with the operators confident of victory. For several weeks the operators have been making preparations for the final contest, the re-opening of the mines. A force of over 200 deputy sheriffs has been recruited, a large proportion of them men who have had experience in this kind of work, and careful plans have been made for the fight anticipated as likely. Officers of the National Guard of Utah and of the regular army have studied the ground carefully, and have agreed that a comparatively small force of fighting men can protect the mines if properly placed; but there is little likelihood that troops will be called for, at least until after the approaching election. Governor Spry will call out troops only as a last resort. The operators are inclined to think this will not be necessary, although there are some who would like to shift the burden of expense upon the state, the deputy sheriffs being paid by the mining companies. During the waiting game, the position of the Western Federation of Miners has been steadily weakening. Hundreds of men have left the district, and there have been numerous defections from the ranks, especially among the skilled workmen. Charles H. Moyer, president of the Western Federation, has been making many threats about calling strikes wherever the 'Utah Copper crowd' or the Guggenheims are interested, but all this time he has been losing control of his men at Bingham. Dynamiting is not the popular pastime it once was, and the operators have refused to be scared. Word was sent to D. C. Jackling, general manager for the Utah Copper Co., that the recognition of the Western Federation would be waived if the other demands were conceded. In some mysterious way this communication was 'lost,' and the conference hoped for by the strikers was not held. Meanwhile, the Utah Consolidated started work with a small force, protected by deputy sheriffs. The Utah Copper followed, with one steam-shovel in operation and about 200 men (according to company statements) at work. There was some desultory long-distance firing, but no serious damage. The bitterest feeling was over the beginning of evictions from company houses occupied by strikers. Moyer and his lieutenants openly incited the strikers to resist this by force, and the first day's attempts resulted in the wounding of one Greek striker. The plan of the Utah Copper Co. is to increase the force steadily, giving the men protection, until the full crew is at work. It is not believed this can be accomplished without violence, and every preparation has been made to cope with this. The other mines will follow in the wake of the Utah Copper.

The Tintie operators have averted a strike by an increase in wages. Here the principal trouble came from the shovelers. Under the new schedule an advance of 25c. per day is granted, shovelers receiving \$3, hand-steel miners \$3.25, and machinemen and timbermen \$3.50 per day. The Tintie operators have felt that they wanted to make

hay while the sun shone, and that they could better afford to pay the increased wages now and take advantage of the high prices for lead, silver, zinc, and copper than to close down and perhaps have to sell their product later on a lower market.

The strike in Bingham is making itself felt, although the effects have not been so serious as they might have been were general conditions less prosperous. 'Bumper' crops are now being marketed, and other districts are increasing their production, but the loss of the money put into circulation by the operation of the Bingham mines cannot fail to be of importance. Utah Copper reached its maximum production in August—11,841,044 lb.—and the greater part of the cost, claimed to be 7c. per pound, is for labor. One effect is at the smelters, where curtailment is in progress, the International having closed down its copper furnaces.

### TORONTO, CANADA

HOLLINGER MILL RETURNS.—DISCOVERIES OF ORE.—PROGRESS AT COBALT.

Owing to satisfactory reports from the mines, the market for both Porcupine and Cobalt shares has considerably strengthened lately, and the volume of transactions has greatly increased. The Hollinger, with 30 stamps in operation, is treating 300 tons of ore per day, and the September clean-up is unofficially estimated at about \$300,000. The additional 10 stamps will shortly be running. The recovery of gold amounts to 98%. A statement is promised about the first of the new year and there are rumors that a dividend may accompany it, the company being in a position to make a distribution of profits if it is considered advisable. The Dome is in the same fortunate situation as regards profits, but it is understood that the policy will be to apply them to the liquidation of outstanding liabilities before undertaking to make any return to shareholders. Another tube-mill and slime press are being added to the plant, which will increase the capacity of the mill to 450 tons per day. The inclined tramway from the rock-house has been continued down to the 100-ft. level, and ore can now be taken to the mill from both the 60 and 100-ft. levels, the supply from these two levels being estimated as sufficient for a mill of the present capacity for ten years. The transmission line from the power-plant at Waiwaitan Falls to the mine is nearly completed, and is expected to be in operation early in November. At the McIntyre the foundation for the new mill is under way. It will be a cyanide plant, equipped with rolls, tube-mills, and Chilean mills, in two units, the first two of which it is hoped to have ready by January 1. The ore in No. 4 shaft at the lower levels, which is not suitable for amalgamation, will be reserved for this process.

The recent discovery at the Pearl Lake of an orebody 18 ft. wide, showing good gold content at the 400-ft. level, is regarded as of considerable importance, as it checks the result of diamond-drilling on this vein, and gives a reasonable assurance of profitable development on the 800-ft. level, at which diamond-drilling gave encouraging results. The Dome Lake has begun excavations for a 10-stamp mill. Ore has been found at the 180-ft. level, which is so far the deepest working of the mine. At the McEneaney the developed ore is estimated at \$750,000, of which over \$90,000 is on the dump. The first five stamps of the mill will be ready for work in November, and five more will be added in the spring. For the present, recovery will be made on plates and the tailing retained for further treatment in a storage dam. The difficulties between a large number of the shareholders and the directorate of the Crown Chartered have been amicably settled. The company has been reorganized and the former directors replaced by a body largely representing Toronto interests, and the indebtedness of the company to J. P. Heffernan and L. H. Henault, amounting to \$140,000, wiped out by the creditors accepting stock in the new company at 25c. per share. The head office has been moved to Toronto.

## General Mining News

### ALASKA

#### FAIRBANKS

Claims on Fairbanks creek from four above to nine below, inclusive, have been optioned to J. Funchion and J. T. Cowles, who will probably dispose of them to the Alaska Exploration Co., which has a dredge on Fairbanks creek. A big clean-up is reported as having been made on September 10, on three above Fairbanks creek, by Gustafson & Griffin, when from four days' run they recovered \$7000 in coarse gold. Eight men were employed shoveling the pay-dirt. The Little Giant mill being erected on eleven above, creek claim, is nearly ready to crush ore from the Pennsylvania claim. Veins of quartz 12 to 36 in. wide, containing gold, have been found at the head of Independence creek near Circle. An electric hoist has been installed at the Free Gold claim, on Bedrock creek, and the mill is working steadily. J. F. Zimmerman has optioned his interest in the Rainbow quartz claim to R. E. Maddocks and G. Nightingale for about \$20,000. A good deal of work has been done here; 65 tons averaged \$38 per ton at the Chena mill; and 40 tons of ore is sacked and 100 tons on the dump.

#### IDITAROD

It is stated that the Guggenheim dredge at Flat creek is working at a loss on the old tailing in the worked-out portions of the creek; but when the machine reaches the untouched ground which prospecting proved to contain gold, results should be good. Riley and Marston, the largest owners on Otter creek, have bought the balance of the ground on the creek for \$75,000 cash. Six additional plants will be installed next season. The Summit claims, at the head of Flat creek, have been optioned to J. Ford for \$60,000.

#### JUNEAU

The Alaska Gastineau Mining Co., of San Francisco, is installing a complete electric drive equipment supplied by the General Electric Co., at its mines at Juneau. Included in the plant are a 1750-kw. water-wheel type generator, one 200-kw. generator, one 150-hp. motor; 35, 45, 50, and 75-kw. motor-generators; three 1250 and 500 kva. transformers, switchboards, and an electric mining locomotive.

During August the two 120-stamp mills at the Alaska United worked 30.74 and 30.53 days, crushing 18,648 and 20,706 tons, respectively, with a total output of \$111,583, and a realizable value of \$110,467. There was saved 951 tons of concentrate. Operating expenses totaled \$46,255, and construction \$10,840, and the net profit was \$53,372. Development covered 153 ft. in the Ready Bullion claim, and 352 ft. in the 700-Ft. Claim, the stock of broken ore increasing 5767 in the former and decreasing 2348 tons in the latter.

#### NOME

The steamer *Victoria* arrived at Seattle from Nome on October 16, carrying 552 passengers, \$1,500,000 worth of gold, and furs valued at \$500,000. The *Victoria* is leaving again this week for the last trip this season to Nome. Many miners are returning to the States for the winter.

#### VALDEZ

The largest mining deal ever made in this part of Alaska has been completed, in which the Midas Copper Co. has transferred its holdings of 12 claims on Solomon gulch, to the Alaska Syndicate. The original partners put in an adit 300 ft., 70 ft. of cross-cutting, and 75 ft. of raises, being in ore all the time, and shipments to Tacoma returned 9.5% of copper and gold content worth \$5 per ton. The property is situated about 4½ miles from the bay at an elevation of 800 ft. Good water-power is available. The new holders intend to spend a large sum of money in development, tramway, wharf, and machinery, before any ore is shipped.

### ARIZONA

#### COCHISE COUNTY

At Tombstone, a case involving title to a placer claim in Ash canyon, in the Huachuca mountains, which was staked during the rush about a year ago, has been decided in favor of Quarles, who sued Harper. One large nugget was found on the claim.

The Great Western Mining Co. is shipping three cars of ore per day to the El Paso smelter, and 90 men are employed. The Calumet & Arizona has 60 men on its Courtland property. The reported labor trouble was of little account, and all have returned to work.

#### GILA COUNTY

A number of officials of the American Smelting & Refining Co. have been inspecting the Hayden smelting plant. It is stated that the smelter will probably be enlarged soon. The Douglas Copper Co. and others operating between Ray and Superior have been notified that, early in January, the Hayden smelter will be ready for custom ore.

#### GRAHAM COUNTY

The Arizona Copper Co. is augmenting its power station equipment by installing new electrical apparatus, among which are eight General Electric rotary converters, four of 300 kw., two of 150 kw., and two of 125 kw., respectively; also 12 transformers of 125 kw. and 12 of 60-kw. capacity.

#### GREENLEE COUNTY

The Detroit Copper Co. is making several alterations at its plant. The new steam turbines have arrived, while two new boilers are being built in. Owing to overhauling gear in the converting department, this month's output will be lower than usual.

#### YAVAPAI COUNTY

The Speck Mining Co. has sold its dredge on Lynn creek to the Hydraulic Gold Mining Co., as it intends to work its placer ground by the hydraulic process. The latter company intends trying the old Lynn creek hydraulic workings, with the dredge, of which there are several thousand acres. The Speck company's recent dredging has yielded 60c. per cu. yd. This is a case of two companies exchanging methods of working, due to configuration of the country. It is generally reported that the United Verde Copper Co. has practically bought the old dumps, aggregating 850,000 tons, at the Congress mines, at \$1 per ton. The tailing contains a high percentage of silica and some gold, and will be used for fluxing purposes. A steam-shovel will move the tailing to the railroad cars.

### CALIFORNIA

#### AMADOR COUNTY

It is reported that in sinking in the Keystone shaft, Amador City, a belt of mariposa slate has been found on the hanging wall side of the shaft at a depth of 1900 ft. This is probably the same belt which is known to outcrop several hundred feet east of the shaft, on the eastern slope of the hill.

#### BUTTE COUNTY

The old Gold Bank mine, at Forbestown, has been purchased by M. J. Cooney, of Oroville, and F. J. Stoer of Oakland, from H. P. Stowe, of the latter place, who was the owner. The mine was shut down seven years ago, and had produced bullion worth \$2,500,000. A 40-stamp mill and cyanide plant is to be built, and a number of miners are already at work.

#### CALAVERAS COUNTY

An old mine near Valley Spring is being inspected by Mr. Warner, of the Kings quicksilver mine, which is said to look promising. The former property will be offered to San Francisco people.

#### NEVADA COUNTY

Development at the Birchville mine, near Graniteville, has opened a new ore-shoot 3 ft. wide, and averaging \$20 per ton. The company plans to erect a new stamp-mill to replace the plant destroyed by fire some time ago. An

electric power-plant may also be installed. H. Kitto and company have started their dredging plant on Deer creek, below the Kendrick placer. The dredge is operated by electric power, works smoothly, and has a fairly large capacity. At the Kirkpatrick mine, near the Mountain House, a large adit is being driven to under-cut the gravel deposit. It is in 400 ft. and must go 250 ft. farther before a raise is started. Machine drills are used, and the rock is hard. Improvements are being made to the surface plant generally.

A new 22-hp. electric hoist has been installed at the 800-ft. level of the Sultana mine, also an electric pump. These take the place of machines driven by air. A 150-hp. compressor is being erected. Work is being pushed in the 800-ft. level winze, which shows good ore.

#### SAN BERNARDINO COUNTY

The Skidoo mine is not working full time on account of the 15-stamp mill crushing lessees' ore. The mine and mill employ about 50 men. The Tuber Canyon mine has six men getting the workings in order. A mill, consisting of two batteries of three stamps each, Merrill equipment, and a 45-hp. gas engine is being erected. Busch brothers, of Denver, have started work at the Happy Canyon silver property.

### COLORADO

#### CLEAR CREEK COUNTY

The Dives-Pelican, Seven-Thirty Mining & Milling Co., with a capital of \$116,000 has been incorporated. The compressor at the Burleigh adit was started last week, and the many lessees on the Dives-Pelican and Seven-Thirty workings can use machine-drills. The new sampler has been connected at the Capital mill, and it will now deal with any ore sent in from lessees. The Bard Creek company has made an initial shipment of six tons of clean galena ore. About 450 ft. has been driven on a vein which is 4 to 24 in. wide. Denver and Georgetown men are interested. A custom concentrating plant is needed at Georgetown, as there are a number of mines in the vicinity which could be worked profitably if such a mill were within easy reach of them all. The nearest custom mill at present is at Idaho Springs. The Silver Plume adit has been driven about 1600 ft. into McClellan mountain, cutting several veins of a promising character.

#### GILPIN COUNTY

At a depth of 260 ft. in the shaft of the Gilpin Orion mine, the vein is 7 in. wide, carrying a fair percentage of copper, and worth \$158 per ton. A shipment of five tons is ready for the smelter. Other small shipments have yielded good returns. The Pittsburg Extension has been mining good ore on the 160-ft. level; Quintress & Co., leasing on the 1000-ft. level of the Grand Army mine, shipped 45 tons of ore yielding \$15 per ton; a rich shoot of ore has been opened on the 800-ft. level of the Alps mine; good shipments are being made from the 100-ft. level of the Bates, in Chase gulch, and good progress and shipments are being made at the Square Deal, in the Lake district.

#### GUNNISON COUNTY

It is stated that the Colorado Fuel & Iron Co. is about to start working a large deposit of bog iron ore, situated about two miles from Crested Butte. The company has 160 acres of ground, and the deposit is from 10 to 15 ft. thick. The ore is practically free from phosphorus. After the broad-gauge railroad is completed over Marshall pass and into Crested Butte, shipments will begin to the Pueblo smelters. The Lead King mine employs a number of men, and several thousand sacks of ore containing copper, zinc, and lead are ready for hauling to the railway at Marble. A peculiar state of affairs is said to exist at the Black Queen mine. The property has been a good producer, but the mine is now full of water, the mill closed down, and the owners are not bothering much about it.

#### LAKE COUNTY (LEADVILLE)

The September tonnage was in advance of that of August, this being caused by a number of lessees being able

to return to work on account of surface water subsiding. From outlying districts the tonnage was increased, while the large producers remained about as usual. The mining situation throughout the district is good, due to the steady advance in metal prices enabling lessees to work almost everywhere, and zinc buyers are bidding for ore as low as 20%, this being 10% lower than the contract basis of a year ago. During the past week one contract was signed for 1000 tons of ore at a flat rate of \$5 per ton for 22% zinc. There are 74 producing mines in the area bounded by Birdseye on the north, to Empire gulch on the south, east to the base of Mosquito range, and west to the Half Moon, Sugar Loaf, and St. Kevin. Additional roasters are being started at the Arkansas Valley smelter on account of ore received.

#### TELLER COUNTY (CRIPPLE CREEK)

The flow from the Roosevelt drainage tunnel is now 9870 gal. per minute, and water is receding from the Gold Coin, Granite, and Mary McKinney at a satisfactory rate. To offset the construction of a fourth drainage tunnel, and to prove to the mine-owners of the district that pumping by electric power to the level of the Roosevelt tunnel would save them money in the end, a leading engineer has made estimates of such pumping, which have

ROOSEVELT DRAINAGE TUNNEL. INTERMEDIATE SHAFT.

been submitted. If the tunnel costs \$600,000, interest and depreciation would be \$90,000 per annum; and for this sum it is estimated that the water could be pumped as suggested. Two shifts are being worked at the Anchoria-Leland mine, Gold hill, and there are also four sets of lessees at work. An electric hoist may be installed at the Chickenhawk shaft on Guyot hill, which shaft-house was recently destroyed by fire. Lessees at the Joe Dandy shaft, on Raven hill, will install a 100-hp. air-compressor. This mine produces about three cars of ore per week.

### IDAHO

#### SHOSHONE COUNTY

The Tamarack & Custer Consolidated Mining Co. is resuming operations, and the Rex mill, at Nine Mile, has been leased. The lease includes the long aerial tramway, which will be used for carrying ore from the Tamarack property. The mill has a capacity of 400 tons per day. Spokane men have secured control of the Alice and will start work soon.

Two shifts of miners are employed at the Hypotheek,  $3\frac{1}{2}$  miles south of Kingston, driving on the 523-ft. level, which is 750 ft. from the surface. Three cross-cuts have been extended from the level, the first having cut some carbonate ore, the second showed galena and iron pyrite, and the third is now out 35 ft. Development generally has been encouraging. The 700-ft. level is to be pumped out, and work will continue through the winter. Claims on Pine creek have been examined, with a view to submitting them to Spokane mining men. Good surface showings have been uncovered, some yielding a high percentage of antimony. A meeting of the Silver Rock was held at Wallace, and directors and officers elected for the coming year. The adit is now in 275 ft., and a further 100 ft. will be driven. At a depth of 175 ft. some gray copper has been found. Over 1000 ft. of work has been

done on the Clear Grit claims on Beaver creek. Trenching has uncovered ore for 150 ft., that returned 52% lead and 61 oz. of silver. The United Lead, near Osburn, is to build a mill.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—Production from the Ernestine mine for September was 25,500 oz. of gold and silver bullion, and 10 tons of high-grade concentrate. The usual monthly dividend of 1% was declared October 1. The mine is in good shape. Development at the Deadwood mines is opening from 4 to 7 ft. of ore on the 500-ft. level. The Oaks Company shipped 420 tons of ore, valued at \$17 per ton, during September. The Socorro mill crushed over 4000 tons in September. The 700 and 800-ft. levels are opening plenty of ore. An electric hoist will be placed over the winze in the Little Charlie adit, which continues to yield a good tonnage of high-grade ore.

Mogollon, October 11.

## MONTANA

### BEAVERHEAD COUNTY

The famous old Hecla mine of the Hecla Consolidated Mining Co., west of Melrose, has been purchased by the Longmaid family of Helena. These operators will rehabilitate the mine at once, installing new machinery and pushing development.

### FERGUS COUNTY

The Barnes-King Development Co. expects to be producing and treating ore before the first of the year, from the newly acquired North Moccasin group. The work of retimbering the caved shaft on the property has not proved as difficult as anticipated. It appears that only the first hundred feet of the shaft has caved, the lower part being uninjured. Electric power is to replace steam entirely at the property.

### GRANITE COUNTY

The old mining camp of Garnet, above Bearmouth, was almost wiped out by fire last week. The business part of the town suffered the heaviest loss.

### JEFFERSON COUNTY

The Mount Washington mine, at Wickes, mentioned recently, is now producing about 50 tons of ore per day worth \$25 per ton. This ore is coming from above the 100-ft. level from stopes 6 ft. wide. Some development is under way on the 200-ft. level, and the shaft is to be sunk deeper.

### LEWIS AND CLARK COUNTY

There is renewed activity in the Marysville district. Besides the work on the Bald Mountain property, the Bald Butte property is also producing, running its mill regularly. Machinery is now arriving for a cyanide plant for the St. Louis Mining Co. It is said that the Barnes-King Development Co. has enough ore in sight in the Gloster-Piegan property to justify the erection of an up-to-date cyanide plant, and that this work will be undertaken shortly.

### SILVERBOW COUNTY

(Special Correspondence.)—The Original mine, of the Anaconda company, is being equipped with the compressed air system and is shut down for about two months. During September the mines of the Anaconda company were not worked on Sundays, owing to a surplus of ore at the smelters, this being due to alterations at the Washoe plant. The Anaconda company is sinking the shaft of the Tropic, a claim east of the central part of East Butte, which is down about 500 ft., but has not been worked for some years. The rest of the machinery for the Butte Central Copper Co.'s concentrating plant has arrived, and the mill will be ready for work in a few weeks. Work in all coal mines of Montana has been stopped, pending the vote on a new wage scale. This will be binding for two years, and work should be resumed in a short time. The Anaconda company recently ordered 12 auxiliary hoisting engines from the Nord-

berg company of Milwaukee, and the first has been started at the Tramway mine.

Butte, October 7.

The cross-cut on the 2800-ft. level of the North Butte is in 15 ft. in the Jessie vein, and 3½ ft. of the ore is glance and bornite assaying 40% copper, while the whole averages 11%. This is the best find made in Butte, since those on the 1620 and 1800-ft. levels of the North Butte some years ago.

### YELLOWSTONE COUNTY

Butte business men are investigating some prospective oil lands near Billings. When drilling will be commenced has not been made public.

## NEVADA

### ESMERALDA COUNTY

The Florence Goldfield is again shipping ore worth \$100 per ton from between No. 5 and 7 levels, or 250 to 350-ft. depth, the levels in this mine, down to the seventh, being only 50 ft. apart. The main shaft is being sunk 70 ft. below the 1200-ft. level, and is making a considerable quantity of water. Sinking is again in progress at the Merger, in the main shaft, which is down 1400 ft. The cross-cut started at 1330 ft. is now being driven about 15 ft. per day. Development on the Deserted claim of the Silver Pick Consolidated is making good progress, and fair assays have been obtained from the drift on the 260-ft. level, which is now near the boundary line of the Mohawk. Driving northwest and southeast is in progress at 320-ft. depth of the Lone Star. Lessees are working from the main shaft of the Combination Fraction, and they have a good chance of making a profit from their work. At the C. O. D. Consolidated, the main or Gold Bar shaft, and the Victor and C. O. D. M. & L. workings have been leased to a company organized by C. S. Sprague, of Goldfield. A report by G. C. Webb shows that there is a large quantity of ore in the property, and it will pay to further open the orebody and erect a mill. The Blue Bull shaft is nearly 600 ft. deep, and at 700 ft. development will be started. The Diamondfield Black Butte is breaking ore in three places, and shipments will be resumed shortly. The heavy snow-storm which fell at Goldfield on October 11 was the heaviest on record for so early in the season.

### LYON COUNTY

At the New Yerington, drills are working in the adit 75 ft. east of No. 1 stope. The adit is in about 520 ft., the face being at about 260-ft. depth. At 800 ft. east of the face, an adit has been started and driven 100 ft. in the direction of the west side of the adit. There is a good deal of high-grade ore in both adits. Smith brothers, who have a lease on the old Empire Nevada ground, have shipped to date 56 cars of ore to the Thompson smelter. The ore averages 6% copper. The McConnell Mining Co. has purchased a 10-ton Mack auto truck and 5-ton trailer to haul ore from the mine to the railroad.

After less than 14 days run, the remodeled blast-furnace at the Mason Valley plant has smelted 955 tons in 24 hours.

### MINERAL COUNTY

From Salt Lake comes word that C. E. Knox and J. H. Miller, and the Knight company have secured the properties of the Cain Consolidated company, a group of 50 claims at Aurora. The production from these mines is said to be \$17,000,000. The adit, which is in about 1100 ft., will be driven 1000 ft. farther to cut the old Humboldt vein, which yielded so much in former days. The camp now has the advantage of having electric power. The present 20-stamp mill will be experimented with, and perhaps the whole plant remodeled.

### NYE COUNTY

The Tonopah & Goldfield Railroad Co. reports that, for the year ended June 30, its revenue was \$760,442, and net revenue \$299,772. The surplus stands at \$782,812. A cross-cut from a depth of 60 ft. in the raise of the Big Four mine, between the 400 and 500-ft. levels, has exposed 40 ft. of ore, worth \$15 to \$25 per ton. Further work has

proved this orebody at 480-ft. depth. On the 200-ft. level two large veins of good grade have been opened in the east drift. At the 400-ft. level, and adjoining the glory hole, a lode 10 ft. wide, worth \$75 per ton has been opened. The Merten-Cantwell lease, on the Manhattan-Crescent, cut a rich vein, 10 to 16 in. wide, last week; and now a second lot of ore has been cut. From a small quantity of ore the lessees panned \$150 in gold. Rich ore has also been found in the Kendall-Douglas lease of the Manhattan Consolidated; and the Crampton lease on the Tiptop claim of the Seyler-Humphrey company.

The old drill of the Tonopah Potash Co. is now drilling for artesian water, in the northern part of Railroad valley; but the company will sink several more holes in the valley for potash.

The annual meeting of the Montana-Tonopah Mines Co. was held at Tonopah on October 1, when 771,507 shares were represented. Proceedings were of a formal nature. Cash in hand on August 31 amounted to \$230,945. A new orebody, 5 ft. wide, was cut on the 565-ft. level, and is a faulted portion of the Shaft vein. Further development of the rich orebody cut on the 1250-ft. level of the North Star proved disappointing, as in driving east and west, high grade ore soon gave out. After the former drift was extended 30 ft. in low-grade ore it broke into 2 ft. of rich ore, containing a high percentage of gold as before. The west drift also is in good ore. A shipment of 48 tons of ore was sent out from these workings. At the Halifax, the west drift from the north cross-cut, on the 1400-ft. level, which has been driven 75 ft. on the contact of rhyolite on the hanging wall, and andesite on the foot-wall, and which showed low-grade quartz for a while, now shows 4 ft. of sulphide ore of high grade. Stations are being cut at 800 and 1000 ft. in the shaft, where quartz 2 and 4 ft. wide, respectively, was cut in sinking. At the 500-ft. level stopes of the West End the orebody is 40 ft. wide and of a good grade. During September the mill produced 45 bars of bullion and 75 tons of concentrate. The Montana-Tonopah September return was 63 bars of bullion and 35 tons of concentrate from 4473 tons of ore treated. During the week ended October 5 the Tonopah Mining Co.'s mill dealt with 3365 tons averaging \$18.50 per ton, with 90% extraction. Shipments included 32 bars of bullion and 22 tons of concentrate, of a total value of \$56,000. From all the Tonopah mines in the week ended October 12, the production was 10,509 tons valued at \$262,725.

#### STOREY COUNTY

At the C. & C. pumping shaft, on the Comstock, the second vertical pump is being assembled prior to being lowered to the 2500-ft. level, when No. 1 hydraulic elevator will be taken out. Interest is being taken in the work being done at the Concordia-Mexican Mining Co.'s claim, in the Silver Star district, about a mile east of the north end Comstock mines. The shaft is 156 ft. deep, and a vein has been cut 48 ft. east of the shaft, where it is 2 ft. wide. Other development has met with encouraging results. During the week ended October 12, the Mexican treated 576 tons of ore having a total value of \$27,024, of which 436 tons, averaging \$58.53, was taken from the north stope on the 2500-ft. level. The new cyanide plant at the Ophir is completed, and is now treating tailing stored in the pond west of the plant. The Consolidated Virginia has been driving at the 2300-ft. level, the present face being in vein formation. The Yellow Jacket mill is crushing 968 tons of ore from the Crown Point mine, in which stoping continues on the 1400-ft. level.

#### WHITE PINE COUNTY

On the morning of October 15, 200 men going to work at the Steptoe smelter at McGill, were met by 50 Greek and Austrian strikers, and were driven away with clubs and revolvers. The furnaces are being worked by 350 men within the stockade. Nearly all the American smelter-men, including machinists and carpenters, have joined the strike against the Nevada Consolidated company. Several acts of violence have been reported during the past few days.

There is little change in the strike situation at Ely, settlement apparently hinging on affairs at Bingham, where a start has been made with a few men. Good order prevails at the former town. The stores are only selling goods for cash, and the mining companies are not forcing the men out of their houses as at Bingham. Departures from the town are from 50 to 75 per day, many Greeks leaving on account of the war in Europe. The Giroux has made no effort to pump out the Giroux shaft.

### OREGON

#### BAKER COUNTY

The Mammoth mine is being reopened, and is now being pumped out, the mine having filled with water ten years ago, and this is the first time it has been drained since. The shaft is 400 ft. deep and has cross-cuts and drifts every 100 ft. A new boiler and other machinery has recently been installed. It is intended to soon start shipping copper ore from the claims of Haas brothers, below Ballard Landing on Snake river.

(Special Correspondence.)—The Cornucopia Mines Co. is installing additional apparatus in its power plant, consisting of a 400-kw. General Electric water-wheel type generator with a 14-kw. exciter; also six 150-kw. transformers and a switch-board.

Baker City, October 7.

### UTAH

The fifty-third dividend of the Grand Central, amounting to 5c. per share, or \$25,000, will be paid on October 25. The total to date is \$1,652,000. The Iron Blossom has declared a dividend of 10c. per share, payable October 25. During the current year this company has paid \$370,000 in dividends. A good deal of activity is taking place in shares of Prince Consolidated of late.

#### SALT LAKE COUNTY

During September lessees at the Michigan-Utah mine shipped 511 tons of ore valued at \$36.24 per ton. From July to September, inclusive, 1032 tons was sold, with a total net aggregate value of \$36,505 in gold, silver, copper, and lead. The Michigan-Utah tramway is in operation, and will help to reduce costs to some extent. Another block on the Darlington claim has been leased, and the lessees will work along the old Lavinia vein.

#### SUMMIT COUNTY

Ore shipments for the week ended October 12 were 474 tons from the Silver King; 430 from the Daly West; and 376 from the Daly-Judge mine. The Daly West has declared a dividend of 15c. per share, totaling \$27,000. Adjustments and improvements are still being made to the Ontario mill; but satisfactory results are being shown by the new process used. The Revelator, at Snake creek, is opening in a promising way; and new machinery is to be installed. Work at the Bonanza is confined to the 300-ft. level, where a fair quantity of ore has been opened.

#### UTAH COUNTY

The American Ozokerite Co. of Colton is about to make a third shipment of its product to the Eastern market. Utah is one of the few places where this valuable mineral is found. The company has 40 men at work and has spent \$135,000 to date. The mill of 100 tons capacity per day is working full time. The veins in this district are from 2 to 30 ft. wide, and average 3% of mineral wax, or ozokerite; and by the process employed, it can be produced cheaply. The largest quantity of solid wax found in the belt was in a shoot on the property at Soldier Summit; while a good deal of nearly pure wax has been taken from claims extending from Media, at the Acme property, to the various claims around Colton.

### WASHINGTON

#### FERRY COUNTY

(Special Correspondence.)—Officials of the Washington Water Power Co. have visited the Republic district, and are considering whether there is enough business to justify extending the power-line from the Spokane plant to sup-

ply the mines and mills. This would mean the building of a 60,000-volt line 110 miles long, and would include the mines of the Chewelah district. The cost of electric power would probably be one-third that of steam power. A good display of minerals was shown at the Spokane fair last week; and E. V. Shannon, a 16-year-old boy from Kellogg, Idaho, was awarded the prize for the best educational mineral display from the Coeur d'Alene district. The Empress Mining Co., of Wallace, got first prize for silver and lead ore specimens. Eight state governors and about 500 Alaskans are expected in Spokane for the American Mining Congress meeting, November 25 to 29. The Hope company, of Republic, will build a mill costing \$50,000.

Spokane, October 10.

## AUSTRALIA

### NEW SOUTH WALES

During the quarter ended June 30, the Great Cobar company treated 100,345 tons of ore for 2058 tons of copper, 14,397 oz. of gold, and 72,156 oz. of silver, valued at \$1,160,000. The new concentrating plant is treating 200 tons per day, and the tailing stacked for flotation process. The second unit is about ready.

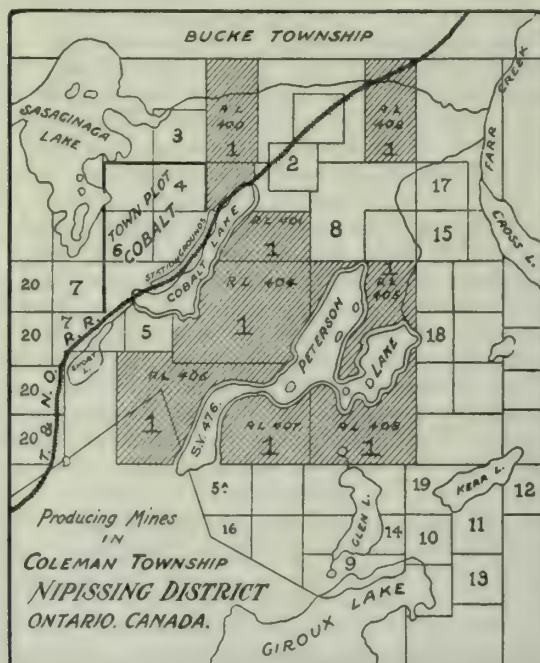

### QUEENSLAND

The gold output from the mines in this state was valued at \$630,000 in August, a decrease of \$68,000 compared with last year. The total yield for the first eight months is \$4,900,000, a decrease of \$380,000. There has been a decline in production at Charters Towers and Gympie, and increases at Mt. Morgan and other small centres.

## CANADA

### COBALT

During September 52 cars containing 1779 tons of ore were shipped from the district. With the starting of extra

stamps at the Northern Customs concentrating plant, shipments of low-grade ore have decreased. The Crown Reserve sent all its ore to the old Nova Scotia mill. Excavating for foundations of the Lucky Cross mill, at Swastika, is nearly finished. A good site has been chosen on the banks of a creek which flows through the property. The mill will consist of a Blake crusher, five 1250-lb. stamps, copper plates, classifier, one Hardinge mill, Callow tanks, and Deister tables. The mine is opening in a promising way.

### PORCUPINE

The Hollinger Reserve shaft is down 175 ft. and a 5-

stamp mill has been ordered. At the Pearl Lake mine, the shaft is down 500 ft., and is being sunk as fast as possible to 800 ft., where the large lode recently cut will be met without cross-cutting. Some of the mines in the Pearl Lake district were shut down last week, for a few days, on account of lightning striking the power-plant at Sandy Falls. The lode on the 200-ft. level of the McEneaney has been developed 285 ft. south and 240 ft. north of the shaft, showing 7 ft. of ore. Foundations for 10 stamps and 2 tube-mills are finished. At the Vipond, the vein has been opened for 40 ft. at the 400-ft. level, and assays are \$8 to \$12 per ton. The Davidson and Godfrey veins are being opened on the 300-ft. level. At the 300-ft. level of the McIntyre the lode has been cut 130 ft. from the shaft.

## MEXICO

### CHIHUAHUA

The Batopilas Mining Co. reports that in September shipments of bullion containing 54,000 oz. of silver left the mines by way of Nogales, Arizona.

### SONORA

(Special Correspondence.)—The Compania de Minas de Mexico, in the district of Sahuaripa, has its smelter ready to blow in as soon as furnacemen can be procured from the United States. The 40-ton concentrating plant has been in constant operation, while the 100-ton mill will be ready to start on October 15. Shipments of ore are being sent to El Paso, as the bridges burnt by rebels have been repaired on the Tonichi branch of the railroad. The shaft is down 1000 ft., and the ninth level is being opened. About 400 men and 600 pack-mules are working. The men are all contented, and do not wish the mine to close down, and have not been interfered with in any way since starting work three years ago, excepting burning of bridges on the railway. The mules are carrying ore to the railway and wood to the mine.

Tonichi, October 4.

El Tigre mine and mill are being worked full time, according to J. W. Malcolmson, who has gone to Kansas City. The Mexican portion of the district is elated over the \$5000 reward for recovery of 21 bars of bullion stolen by Salazar, which were mostly found by a Mexican private soldier.

On the 500-ft. level of the Democrata mine a large ore-body averaging 8% copper was recently cut. The company's smelter is operating steadily, while new machinery is arriving for the plant. Considerable work is being done at the Superior-Bonanza mine, in the Magdalena district. A new working shaft is being sunk and an adit driven 1400 ft., of which about half is finished. These will be connected later on, the adit serving to drain the mine and transport ore to the railroad. H. Bollweg is manager. The revolution has interrupted the train service, and is reflected in the exports of the state through Agua Prieta. The September exports were valued at \$871,600, against \$1,722,160 in August, while July showed nearly \$2,000,000. The September tonnage was only 6487, against 14,406 tons in August. The Calumet & Sonora company, on the advice of W. H. Weed, has decided to re-treat the past three or four years' accumulated tailing, as it averages \$5.60 per ton. On the 300-ft. level, ore worth \$16 per ton has been cut 125 ft. from the shaft.

## PERU

The Director of Fomento has sent out a circular letter calling attention to the new code of civil procedure which became effective on July 28; and as it affects the operation of the mining code to some extent, all who are connected with pending litigation over mining property, or in any way interested in mines in Peru, should secure a copy of the new law and read article 1344, as it is of importance.

## SOUTH AFRICA

The production of the Transvaal mines in September was valued at \$15,870,000, against \$14,870,000 in the same month of last year.

## Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

MURRAY C. GODBE is at Pioche.  
 LOUIS WEBB is in San Francisco.  
 W. E. PRATT is here from Nevada.  
 CLYDE HELLER is in San Francisco.  
 OSCAR ROHN has been in New York.  
 J. PARKE CHANNING is in the West.  
 M. O. LEIGHTON is in San Francisco.  
 CHESTER W. PURINGTON is in Seattle.  
 C. K. LEITH was in New York recently.  
 P. N. MOORE was in New York last week.  
 C. R. CORNING has returned to New York.  
 W. J. SHARWOOD is at Lead, South Dakota.  
 H. P. GORDON will return to California soon.  
 H. W. REETH has left Finland for England.  
 THOMAS KEARNS is at his ranch in California.  
 F. W. BRADLEY has returned to San Francisco.  
 A. HULSHOFF-POL, of The Hague, is at the Palace.  
 J. MORGAN CLEMENTS, of New York, is at Los Angeles.  
 RICHARD L. GRIDER has gone to Bolivia, South America.  
 GEORGE E. GUNN is visiting the Mason Valley district.  
 D. W. BRUNTON has been in New York for a few weeks.  
 F. H. HELLMAN has returned to New York from the West.  
 GEORGE LE ROYER is now at 1070 Calle Corrientes, Buenos Aires.

ARTHUR J. HIESTER has left Chicago, and is now at Denver.

H. W. MACFARREN is now at 520 Federal building, Los Angeles.

R. H. CHAPMAN was in San Francisco, and has gone to the Yosemite.

CLARENCE BAMBERGER has returned to Salt Lake City from Nevada.

HENNEN JENNINGS is expected in Montana and California this month.

F. E. LAUBE has returned to Bellingham, Washington, from Treadwell, Alaska.

HOWLAND BANCROFT has been in the Magnolia district, Boulder county, Colorado.

C. COLCOCK JONES has returned to Los Angeles from professional work in Montana.

DESAIX B. MYERS has returned to Los Angeles from Calaveras county, California.

F. W. BRADSHAW, general manager for the Tonopah-Belmont Mining Co., is in town.

F. F. SHARPLESS has been examining the DeLamar mine in Idaho and has gone to Joplin.

J. A. HOLMES, Director of the Bureau of Mines, is expected in San Francisco during the week.

R. T. HOPKINS, formerly of the Peregrina M. & M. Co., Guanajuato, Mexico, is at Bangor, Maine.

F. H. NEWELL is now at Helena, Montana, and expects to reach San Francisco early in November.

A. D. MILES is now assistant to A. P. TURNER, president of the Canadian Copper Co., at Copper Cliff.

J. W. MALCOLMSON was in San Francisco during the week and has gone to Kansas City by way of Denver.

F. B. LAWSON, chairman of the board of directors of the Mountain Copper Co., sailed for Japan last Saturday.

H. C. BELLINGER, general manager for the Great Cobar, Ltd., is starting on a four months' holiday to England and other countries.

G. C. BATEMAN has been appointed to succeed A. D. MILES as Canadian representative of the Canadian Mining & Exploration Company.

B. MAGNUS, manager for the Electrolytic Refining & Smelting Co. of Australia, has been appointed general manager for the Mt. Morgan company, Queensland.

V. H. HUGHES is now assistant to the state geologist of Missouri, not geologist as announced in this column on September 21. H. A. BUEHLER continues as state geologist.

## Market Reports

### LOCAL METAL PRICES

San Francisco October 17.

Antimony .....	11-11½c	Quicksilver (flask) .....	41.50
Electrolytic Copper .....	18-18½c	Tin .....	52-53½c
Pig Lead .....	5.35-6.30c	Spelter .....	84-8½c

## Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice or mining, milling, and smelting.

**P**PRICE of tin has caused consumers to look around for a substitute, and aluminum may serve for many purposes. Aluminum foil is being used in Europe to some extent for wrappers, one company using about 110,000 lb. per month.

**D**URING August, the mints of the United States coined 25,101,000 pieces valued at \$1,317,000, as follows: gold, 101,000 pieces worth \$505,000; silver, 2,400,000 pieces worth \$586,000; and copper (one cent) 22,600,000 pieces worth \$226,000.

**M**INERS engaged in bituminous and lignite mining in the United States in 1911 totaled 549,750; and those in anthracite mining were 172,585, making 722,335 in all. The average production per man was 738 tons in bituminous mines, and 524 tons in the anthracite, against 751 and 498 tons respectively in 1910.

**V**ALUE of the brick, tile, terra cotta, pottery, and various other clay products made in California in 1911, according to the United States Geological Survey, was \$4,915,866. This is an increase of \$73,475 over the output of 1910. From Missouri, the value of the above products was \$6,274,353, and New York, \$10,184,376.

**I**N Egypt, coal and other fuels are expensive, but plenty of sunshine can be relied upon at all times of the year. Recently a Shuman sun-heat absorber arrived at Alexandria, from Philadelphia. This plant has been erected at Meadi, near Cairo, and will be used to pump water from the river Nile to irrigate the surrounding land.

**N**ITRATE salts are extremely soluble, and it is unlikely that concentrated deposits will remain anywhere except in places either not subject to or protected from the solvent action of rain, surface water, or moving groundwater. Thus nitrate salts are found chiefly in caverns or caves, or under overhanging ledges, or, as in the Chilean and other South American occurrences, in a region of exceptional aridity.

**P**PEAT amounting to 64,165 short tons, valued at \$311,486, was produced in the United States in 1911. Of this quantity, 51,733 tons was used in the fertilizer industry. It is also used as an absorbent for refuse beet sugar and other molasses, so that these excellent materials can be economically fed to cattle and other live-stock. Charred dried peat is also used in poultry food, and other foods for stock.

**A**IR-BLASTS occur at certain mines in Michigan, South Africa, and Australia, whereby the people are subjected to shocks consisting of a single wave or vibration, followed by a sound of dull thud, as distinguished from an earthquake which consists of a series of waves. On the Rand, R. N. Kotze, government mining engineer, considers that certain shocks owe their origin to the sudden slight subsidence of large masses of ground containing millions of tons on a fault, or over pillars in worked-out areas. Air-blasts have a similar origin, but are mostly due to the weight at great depths, or more probably to the stresses set up by the effects of tectonic pressure, caused by earth movements in the past. When a free face is exposed by mining, the rock has a tendency to crack and disrupt suddenly, and cause serious accidents. At the Brakpan shaft, at 3000-ft. depth, a band of quartzite was passed through which acted in this manner, so sinking was delayed until the sides were lagged.

## Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

**MINING WORLD INDEX OF CURRENT LITERATURE.** By C. L. Breger. 317 pp., index. Mining World Co., Chicago, 1912. For sale by the *Mining and Scientific Press*. Price \$2.

This is a compilation covering the first six months of 1912 of the classified index of the mining and metallurgical literature of the world which is published weekly in the *Mining and Engineering World*. It has been gathered together in convenient form, and the volume will be more useful than the weekly digest. A thoroughly classified index is probably an impossibility; this is one of the best available.

**THE MINERAL INDUSTRY DURING 1911.** Edited by C. Of. 997 pp., ill., index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$10.

The twentieth volume of 'Mineral Industry' differs little in form from its predecessors, but contains some new topics and several authors whose names have not previously appeared have contributed matter. The editing of the volume is poor, and the marked disadvantage of frequent changes in the editorial staff is clearly exhibited in the 10 lines devoted to coal in China, where 9 misprints occur in the conveying of an inadequate amount of information. Apparently, preceding volumes are not consulted in the preparation of a new one. The bibliographies accompanying some of the articles are good, but the value of some of them is decreased by a tendency to restrict references to the *Engineering & Mining Journal*. The data in regard to dredging, for example, are defective for the same reason. Examining the teeth of a gift horse is an ungrateful task, and engineers will be more inclined to regard the convenience of this volume rather than the defects of its make-up.

**THE SURINAM GOLD INDUSTRY.** By J. H. Verloop. 102 pp., ill., maps, bibliography. J. H. de Bussy, Amsterdam, 1911. For sale by the *Mining and Scientific Press*. Price \$2.75.

This book contains some interesting general information of the Guiana gold placer in Surinam, but the inaccuracy shown in giving abstracts from articles on dredging in other countries tends to discredit any original statements made. The book would have been greatly improved if it had been carefully revised by some one skilled in the use of the English language. It could have been reduced in size and made much more interesting and intelligible. Some statements are remarkable, as "There is no technical difficulty that allows of a definite circumlocation in Surinam." This, of course, must be gratifying. Those familiar with dredging in California and Alaska will be surprised by the statement that the "Yuba district produced in 1906 gold to the value of 13 million guilders (\$5,200,000) by the aid of 41 dredges." Also that "shortly after the discovery of gold in Alaska this country produced for no less than 40 million guilders worth of gold \$16,000,000) which had been extracted by dredges." The author has evidently failed to consult the files of the *Mining and Scientific Press* or the publication of the California State Mineralogist, for he says, "as statistical information about the results obtained by gold dredges are lacking, there is very little to be said about it." Mr. Verloop says that the dredge of the Guiana Placer Co. is the fourth dredge to have been tried in the colony, and that the result of working shows a recovery of 1.5 gm. from ground containing 2.5 gm. per cubic yard. It is not stated if this is pure gold. There is a clay overburden of from 2 to 3 metres overlying the gravel deposit, which apparently averages about 1 metre thick. The overburden is dug separately from the gravel and does not pass through the washing plant. No figures of operating cost and yardage dug are given. Several maps and sketches accompany the book.

## EDITORIAL

**C**OSTS are the shibboleth of the mine operator, and their value is only equaled by their inaccessibility. The data regarding operating costs in California which Mr. Charles Janin has compiled will accordingly interest our readers.

**A**NTHRACITE COAL is likely to continue to increase in price, since the deposits are limited, and improvements in methods of working and washing probably can do no more than counterbalance the increasing cost of labor. The highest price in history was reached at Wilkesbarre, Pennsylvania, on October 14, when stove and chestnut sold for \$5.35 per ton net on board railroad cars at the mines.

**A**DVENT of the United States Smelting, Refining & Mining Company in the so-called Dow copper properties of the Lake Superior has been signalized by the election of Messrs. Sidney J. Jennings and C. G. Rice to the board of the Franklin Mining Company, and the same gentlemen, together with Mr. A. F. Holden, to the directorate of the Indiana Mining Company. The steady progress which the United States company has made in its ventures elsewhere makes the new move an auspicious one for the Lake Superior companies.

**M**INERS and metallurgists no less than some of the sons of Erin have 'the wandering foot,' and the graduates of Freiberg have scattered to the ends of the earth in the practice of their profession. The classic mining academy forms a powerful bond of union and it is pleasant to learn that a permanent organization of the Bergakademie graduates living in America is in process of formation. Mr. C. L. Bryden, 1015 Myrtle street, Scranton, Pennsylvania, is the secretary of the new organization, and all Freibergers are requested to notify him of their present address.

**D**RAINAGE of the Cripple Creek mines through an adit lower than the present one has been urged, and the cost of construction as compared with pumping by electric power to the present drainage level is being studied by the engineers of the district. It is computed that interest upon the cost of construction and maintenance will amount to nearly \$100,000 per year, and it is pointed out that a considerable flow can be handled with pumps for this sum, with the additional advantage that if the ore-shoots prove not to persist to the lower level the loss of invested capital will be less.

**W**AR between Turkey and neighboring countries has a direct influence upon the mining industry through the number of Greek laborers it has caused to return to Europe. The drain is already severely felt in some quarters, and the exodus still continues. Southern Europeans form a large percentage of the men engaged in common labor throughout the United States, and if the war is protracted it is likely to assume an unprecedented degree of practical importance to the American public, accustomed to regard disturbances in the Balkans as of similar significance to growing pains in children.

**H**USTLING the East is apparently not so hopeless a task as generally supposed. The taxicab service recently started in Tokyo is reported to be immensely popular, and it is computed that 20 per cent dividends will be paid. One hundred taxicabs manufactured in the United States will be in operation before the end of this year. Tokyo is a large and well paved city, and for long runs the taxicabs have the advantage over the cheaper ricksha, while the competition between the two is an interesting illustration of the limitations and advantages of cheap labor.

**B**USINESS seems not to reflect the uncertainty of a presidential election. Shipments of iron ore down the Great Lakes in September amounted to 7,287,230 tons, the largest on record for that month. The Hendrie & Bolthoff Manufacturing & Supply Company, a well known firm in Denver, has announced that on November 4 it will make a ten per cent increase in the wages of all employees who have been in the employ of the company for more than one year. Several copper mining companies have already increased the wages of their employees as a reflex of the increased profits arising from the increased price of copper, but increased wages paid in general business is cheerful evidence of improving business conditions.

**E**NCOURAGING results from attempts to reclaim dredged lands are elsewhere described by Mr. J. H. Leggett, who has for some years engaged in this work on his farm at Oroville. It should be remembered in this connection that a good deal of dredging land was originally of little value for agricultural purposes, and efforts at reclamation cannot therefore be expected to yield immensely productive areas, but it is evident that the agricultural productivity of land is not destroyed by dredging operations. In Australasia an even more effective method of reclaiming dredged land is enforced by law. Dredges working in agricultural land are required to remove the top soil separately and deposit it upon the tailing. Illustrations of the soil-chutes employed for this purpose have appeared in earlier issues.

**F**INANCING the farmer is attracting a great deal of attention just now, our worthy President having discovered that the American farmer is obliged to pay nearly double the interest rate upon his borrowings as compared with that exacted in France and Germany on no better security. Probably interest rates here continue to reflect the condition of some years ago, when the banker who had loaned a small sum on the security of a valuable herd of cattle might have only bleaching bones to show for it by spring time. Conditions have now changed, farm lands are excellent security for loans, and it is significant that the ratio of automobiles to population is highest in the agricultural states of the Middle West. As has been remarked, the farmer does not deprecate the high cost of living, since he is furnishing the living.

**E**ASTERN financial circles have been in a state of frenzy and brokers hung over the news ticker long after market hours. Quotations were hurled from street to window and arbitrage wires between New York and Boston were unable to take care of the flow of inquiries and replies. But the activity centred about the contest for the world's baseball championship, and the quotations have been the prevailing odds, varying from hour to hour as the progress of games was reported in Wall Street. At 2 o'clock business was practically relinquished and the telegraph service abandoned to the news of the games being sent in from the ball-grounds. That the strenuous business population of New York can so completely give itself up to a mad enthusiasm for baseball leaves little room for criticism of the leisurely

Latin-American, who throws aside business for the *fiesta* and the bull-fight. Now that the world's championship is decided, business can return to its usual routine.

**O**LYMPIC games have begun to obtain a reputation as a source of international bickerings rather than of good-fellowship, if the statements which have appeared in home and foreign journals are to be taken at their face value. The discussion in British journals following the recent contest at Stockholm served to place our cousins across the water in an unenviable light, and it is good to find that, according to Mr. Philip J. Baker, an English athlete of distinction and a participator in the contests at Stockholm, it cannot be considered as representative of the opinion of the intelligent British public. Mr. Baker also completely absolves the American team of the charges of unfairness made against them, and this also we are glad to hear, for it is natural to suppose that where there is much smoke there is some fire. One result of the games is evident, the Americans are instructing the world in the spirit of the twentieth century and bringing home the lesson that successful achievement is based on careful forethought and intelligent preparation in every field of human endeavor.

### Smelter Fume Control

The control of that complex mixture of substances which continually escapes through the chimneys of metallurgical plants is a persistent problem, and one probably incapable of any general solution, because of the variety of factors which must be considered. Increase of efficiency and economy in operation indicates certain feasible lines of progress to the responsible management, while possible effects upon neighboring areas indicate other and at times conflicting lines of action. In addition, the situation has a legal as well as a practical phase, thus introducing new considerations. From the standpoint of the management, the escape of dust is to be prevented, as a source of direct loss, while the escape of gases should be facilitated as aid to minimizing working costs. Thus the interests of the metallurgist and his neighbor coincide, so far as the solid particles of the fume are concerned, while in regard to the gases they are antagonistic. There is a law for liberty and a law for license, and no one will maintain that the metallurgist should be allowed to damage his neighbors without adequate compensation therefor. Among the economic principles which are being more clearly enunciated in the present readjustment of social conditions is the axiom that each industry should properly bear all the burdens incident to its practice, and the smelting industry is not disposed to shirk its responsibilities in this regard. But the restrictions which may properly be placed upon industry require careful study in order that the ideal of maximum good to the maximum number may be attained, and the application of strict legal requirements may operate to cause an economic loss rather than any social gain.

The conditions to be met at any given smelting plant form an individual problem, for which an individual solution must be provided. The successful adoption of the manufacture of sulphuric acid as a means of dealing with the escaping fume of smelter gases was at first hailed as a universal solution of the problem, but it was soon recognized that the abundant supply of the raw materials of fertilizer manufacture and the large market for fertilizer in the neighboring states gave to the Tennessee smelters an advantage not shared by smelters at other points, and it is now generally recognized that acid manufacture is only feasible in certain especially favored situations, and can not serve as a general solution of the fume problem. It is possible that the methods described

by Mr. G. C. Westby elsewhere in this issue may similarly find application where conditions favor their adoption. In some cases methods which add to operating costs may be adopted, as a proper tax upon the privilege of carrying on metallurgical operations, but it is self-evident that only a reasonable tax can be exacted. A commendable amount of study is being devoted to this general question, and a considerable amount of progress has already been made. It is safe to expect that in this, as in other operating problems, a satisfactory solution will in the end be reached.

### The Survey and Its Work

In making his way through unexplored regions the adventurous traveler frequently consults his compass and whatever criteria for guidance he may possess, in order to direct his course, and in every other field of human activity a similar precaution may well be observed. Replying to a criticism that the United States Geological Survey confines itself too closely to the field of practical geology and is not contributing in any large way to the advancement of science, Mr. George Otis Smith, the Director of the Survey, has recently summarized the present work of the organization under his control and its probable influence upon the development of pure science, with commendable clarity of vision and reasonableness of argument. The work of the Survey is of fundamental importance to the geologist, mining engineer, and metallurgist, and it will be worth while to consider briefly its larger phases.

The United States Geological Survey draws its support from the Federal treasury, or, in other words, from all the people of the United States, in order to engage in scientific work of direct value to a comparatively small number of people, though of indirect value to all. It is, therefore, constantly in a position like that of a subordinate department of a large corporation, and must continually demonstrate that the results attained are of sufficient value to justify continuation of the work. It has not, however, to justify its work to those whom it directly benefits, but to the representatives of the larger group from which it derives its support. This fundamental concept is easily overlooked and a neglect to consider this feature is the basis of frequent demands that the Survey engage in this, that, and the other form of activity. Bureaus which derive their support from governmental appropriations commonly lack flexibility of aim, since the funds available are usually restricted to specified lines of work, and it is not infrequently a puzzling problem of management to fit some necessary unusual expenditure into one of the allowable groups. To coordinate necessary and desirable investigation desired by the miner and geologist with activities which Congress can be persuaded into regarding as necessary and desirable is not perhaps the least scientific of the achievements of the personnel of the Survey. This being the case, it is interesting to consider what the Survey is now doing for the geologist, miner, and metallurgist. The work in Alaska is done under an appropriation specifying that the sums provided are to be spent for the investigation of the mineral resources of that northern land. The admirable work that has been accomplished by Mr. A. H. Brooks and his subordinates is too well known to require extensive comment, and it is to be regretted that political considerations have as yet hampered its complete utilization in the development of industry. The work of the Survey on water-supply problems and in the carrying out of topographic surveys is also maintained by specific appropriations for the purpose. The most important phase of the Survey's work in the general field is the conduct of investigations in economic geology. From the viewpoint of the

miner these are the *raison d'être* of the Survey, and any criticism of the Survey by mining men is most likely to take the form of deprecating the expenditure of considerable sums upon paleontologic investigations. It is interesting to note that of the reports now in course of publication, 8 deal with economic geology, 6 with paleontology, 3 with areal geology, and 1 each is devoted to the study of glaciers, mineralogy, petrography, Pleistocene geology, and stratigraphy. It is clear, therefore, that the activities of the Survey are distributed over the whole field of geologic research.

In considering whether the Survey is attaining high efficiency in accomplishing useful results we must first come to an agreement as to what results are most desirable. This is scarcely within the bounds of possibility. The miner, whose needs were the chief factor in securing the establishment of the Survey, not unnaturally considers that his requirements should be preëminent, and tends to regard with impatience investigations which have no visible bearing upon any field of practical endeavor. The pure scientist, on the other hand, considers that the greatest results in the end will be attained from the study of fundamental principles, and regards the policy of the miner in demanding results of immediate usefulness as one of quick returns at the expense of total yield. Eminent paleontologists may possibly regard all the economic phases of geological work as an evidence of a low commercial concept of science and regret the expenditure of appropriations in the tracing of orebodies when such interesting problems as the number of toes on a trilobite still remain unsolved. It is evident that we can never hope to reach unanimity of opinion, since the viewpoint of the worker conditions his judgment.

That economic studies do not contribute to the advancement of science, or that paleontologic investigations are of no economic importance is far from the truth. The results obtained from an investigation depend no less upon the habit of mind with which it is pursued than upon the material studied. Sitting under an apple tree is not generally regarded as a high form of scientific work, and yet Newton's observation of the falling apple was productive of the greatest scientific results. Observations bearing on the fundamental principles of ore deposition can as well be made by the light of a candle in a muddy stope as by the use of a microscope in a well lighted laboratory. Whether any study will serve to throw light upon the fundamental principles of science cannot be predicated in advance, even though it is evident that certain fields of endeavor are more likely to be productive of results than are others. It can safely be said that any investigation, no matter how rigidly practical its scope, will not be barren of scientific usefulness when conducted in a scientific spirit, nor will any investigation of a purely theoretic nature fail to find in time some slight bearing upon practical problems if considered in that light. When the Survey hews closest to the right line of progress it may expect to receive some criticism on every side of its proper field of work, and if such criticism is intelligent and constructive rather than partisan and caustic, the net result will be beneficial. In the past we have criticized as well as commended the Survey, and we expect to continue so to do, believing that the splendid work which it has done and is continuing to do demands the careful attention of all who have the progress of the mining industry at heart. Meanwhile we find ourselves in cordial agreement with the position of its Director in asserting that if the Survey is to continue to deserve the recognition and support of the industry it serves, it must be neither exclusively 'practical' nor exclusively 'scientific,' but by a judicious combination of the two continue to advance our knowledge of the practical by the elucidation of the basic principles of science.

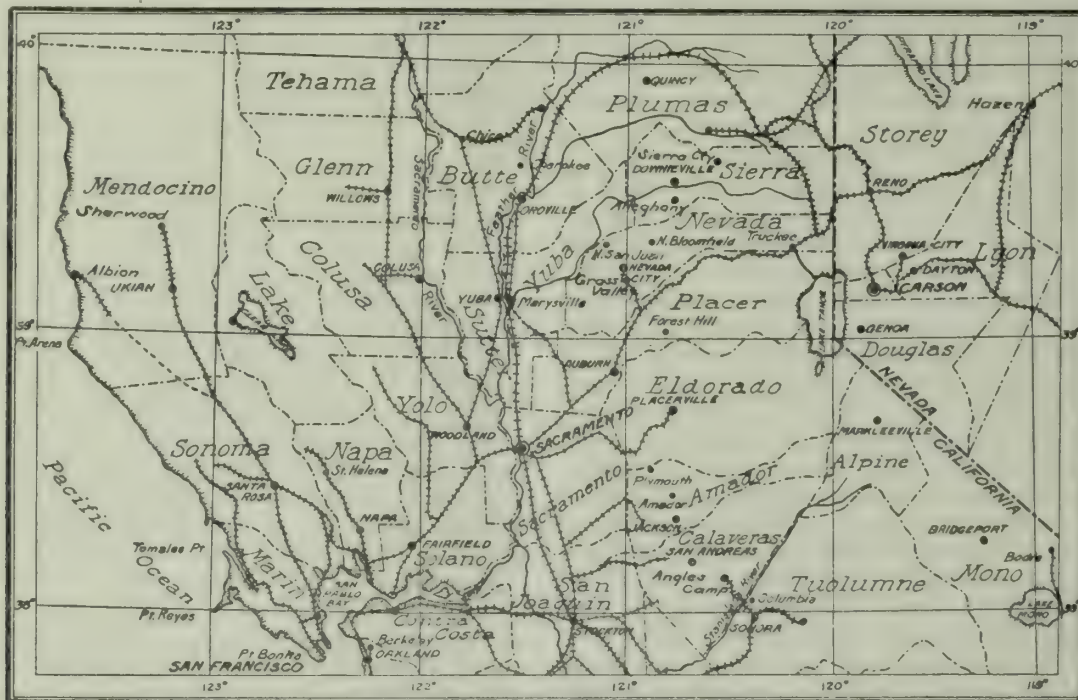

## Operating Costs of California Mines

By CHARLES JANIN

A total of 1,963,296 tons of silicious ore from the gold mines in California was milled in 1910, according to the figures of the U. S. Geological Survey. This ore gave an average recovery of \$5.23 per ton. From the five Mother Lode counties 1,170,497 tons was treated, with an average yield of \$3.78 per ton, and from Calaveras county 365,192 tons was treated with an average recovery of \$2.23 per ton. It is obvious that to mine successfully in this latter county low operating costs must necessarily obtain, and no doubt some examples of 'phantom profits' could readily be detected. It may be mentioned that this low average value is due in part to milling rock taken out in exploratory work in the search for new orebodies.

Operating costs are always a matter of interest to the mine manager or mining engineer, but it is sometimes a

the country rock surrounding the vein, depth of mining, amount of water handled, cost and efficiency of labor, the metallurgical treatment, magnitude of operation, cost of power, and other factors. A knowledge of all these conditions is essential in making comparisons of operating costs, as well as the situation of the mine, and transportation facilities, which involve the cost and difficulty of obtaining workmen, supplies, etc. Mines situated in different localities may be operated under closely similar conditions as regards wages, power, size, and character of orebodies, metallurgical treatment, etc., and comparisons of the operating costs of such mines will be both interesting and instructive. Comparisons between different mines on the Mother Lode, for instance, or between different mines in the Grass Valley district, can be suitably made; but not be-

CENTRAL CALIFORNIA.

difficult matter to obtain costs that are truly representative, or that entirely cover all expenses that should properly be charged to operating. Following are given operating costs of several California mines, some of which are taken from my old note books, and others obtained from the management or some one connected with the mine. While many of these costs are not as complete as could be desired, and cannot properly be used in making comparisons, I believe all of them are of sufficient interest for publication on account of the awakened interest and reported success following the opening of some of the old mines in the state that have been idle for years. Many of the costs I have quoted are results obtained previous to the enactment of the eight-hour law. In general, where cost sheets are available, an appreciable increase in labor cost will be noted, unless offset by great improvements in working methods, since this law has been in effect. Some mines were operating upon such a narrow margin of profit that the increased expense of labor, according to the management, made profitable operation impossible. Others contend that while there has been a general increase in milling costs on this account, mining costs are no higher, the same tonnage per shift being produced as formerly.

The operating cost of a mine is governed, among other things, by the size and character of the vein, hardness of

tween Mother Lode and Grass Valley mines, on account of the widely different geologic conditions, and methods of mining employed.

The lowest operating cost for mining and milling in California, a record for low costs which used to be frequently quoted, was that at the Spanish mine in Nevada county, where a schistose orebody was worked by open-cut, and through an adit previously run, the broken rock falling to the adit-level and from there being trammed a short distance, part going to stamps and part to Huntington mills. The total cost of actual mining and milling was 50c. per ton in 1887, and was afterward reduced to 35c. per ton when treating approximately 6000 tons or over per month. Amalgamation was the only treatment, no attempt being made at concentration. For one period of two months 9000 tons per month was treated at a total cost of \$2300 per month, or about 25c. per ton, distributed as follows: Total crew, 8 men at \$1.60 and 12 men at \$2.50, \$42.80 per day, or \$1284 per month. The power bill was only \$90 per month, and the remainder, approximately \$900, for supplies, superintendent's salary, etc. The crew in 1887 consisted of a foreman at \$3.50, two men at \$3, and eight Chinese at \$1.50 per day. This crew mined 4000 tons of ore per month. Water cost 15c. per inch at a head of 300 ft. The conditions under which the

mine was worked were most favorable for low operating costs, and will probably never be again equaled in this state. Another example of low mining cost is that of the Gopher & Boulder mine in El Dorado county, as stated in the State Mineralogist's report for 1888. The cost of mining in the open-cut was about 20c. per ton, and of mining underground \$1.25 to \$1.50 per ton. The vein had an average width of 30 ft., and was 100 ft. wide in some places. It had a dip of about 65 degrees.

The mine that at present has the lowest operating cost in the state, and which will, owing to the different conditions, compare favorably even with the costs at the Spanish mine, is the Melones mine, where during 1910, 148,900 tons was mined and milled at a total operating cost of \$1.084

carried through a pipe over 4000 ft. long to the bank of the Mokelumne river, where at a head of 415 ft. it supplied power for operating a large air-compressor. The cost sheet for 1907-08 shows a total operating cost of \$2.507 per ton in handling 80,634 tons. This includes allowance for depreciation on parts of the plant. In looking over some old notes, I came across a statement of the Gwin mine for the year ended March 1903; the ore mined and milled during that year was 138,033 tons and the total cost was \$2.285 per ton, being 22.5c. per ton less than for the year 1908. It is interesting to note, however, that the difference of cost is in the amount of development. For the year ended March 1903, charges for development were only \$0.027 per ton as against \$0.251 per ton for 1908;

LEIGHTNER MINE AND MILL, ANGELS.

per ton, exclusive, however, of cost of treating concentrate, about 35c. additional per ton of ore treated. The mine is operated through an adit, the distance to the loading chute being about a mile. The ore is trammed with electric motors to a 100-stamp mill. The stopes are 20 to 35 ft. wide, and in places even wider. Practically no timbering is necessary, a shrinkage system of stoping being employed with pillars left in the orebody. To appreciate these figures one should be familiar with some of the conditions that made such low costs possible, principally the running of an adit that practically obviated the necessity for further development for over 10 years, though during 1910 sinking was started below the adit-level. The power cost is low, the mine owning the water-right, which supplies most of the power, though during the dry season it is necessary at times to purchase electric power. The power cost is mostly for upkeep and ditch maintenance.

The Gold Bank mines at Forbestown, Butte county, some years ago mined and milled 79,689 tons during a period of two years from the Gold Queen mine, the adjoining property, through the Gold Bank levels and shaft. The total cost, including the treatment of the concentrate by chlorination, was \$3.03; the ore was a hard quartz, the country rock diabase, little timber was required, and the cost of water was 10c. per inch at 173-ft. head. This water was afterward caught and re-used for the compressor at a head of about 700 ft. The cost of mining and milling, including chlorination of concentrate, was afterward reduced to \$2.75 per ton at the Gold Bank mine. Development charges could not be properly proportioned to the cost of treating ore from the Gold Queen mine on account of this ore being developed by simply extending the levels of the Gold Bank mine a short distance beyond their former faces. The actual operating cost may be considered as fully covering all expenses incident to ore extraction and treatment, as a royalty was paid on the net proceeds from this ore, and there could be no inducement to show low operating cost.

At the Gwin mine, in Calaveras county, the vein was of moderate width for the Mother Lode, being 10 to 15 ft. The walls were at times insecure, and heavy timbering was necessary. The water furnishing power was twice used, as at the Gold Bank, first at a head of 375 ft. and then

otherwise the operating costs were practically the same for both years. Costs afterward increased to \$3 per ton.

Other mines where the operating costs are available and might be compared to those at the Gwin, are the Utica, at Angels, where the cost for three years preceding 1910 is stated at a little over \$2 per ton, with an output for some

ARGONAUT MINE.

years of over 200,000 tons; the Royal Consolidated, at Hodson, Calaveras county; the Central Eureka, the Fremont Consolidated, and the Kennedy, in Amador county.

The Royal Consolidated, according to some old notes I have, milled 93,155 tons during the year 1903, at a total cost for mining and milling during this period of \$2.93, exclusive of 42c. per ton for concentrate treatment. During part of this time the stopes were narrow and only 20 stamps were running. When the vein was stoped wide and 40 stamps were running, the cost, exclusive of concentrate charges, was reduced to \$2.24. Steam-power was used, the mine was dry, water being pumped 4½ miles for mill and boilers. No timber was used. It is interesting to compare some Central Eureka costs I have for 1903 with those of the present time in that mine. In the former year 43,545 tons was milled, and 42,742 tons in 1911.

	1903.	1912.
Mining .....	\$1.975 }	
Development .....	0.519 {	\$2.823
Milling .....	0.490	0.552
Total .....	\$2.904	\$3.375

Most of this ore came from the 1900 and 2000-ft. levels. Total present costs at the Central Eureka were \$3.375 per ton, for an output of 42,742 tons, according to the report for the year ended April 1, 1912, being \$2.83 for mining and development and \$0.552 for milling. The South Eureka, which adjoins the Central Eureka, has recently developed a large body of ore and has, according to what information I have, an operating cost of approximately \$3 per ton. Owing to heavy ground, and also perhaps to attempting too great an economy in operating, it is stated that several caves have recently occurred in this mine, but no definite information is available. The total operating cost at the Fremont Consolidated, in Amador county, according to the management, was \$2.66, with an output of 6000 tons per month. At the App mine, the late W. A. Nevills claimed an operating cost of \$1.60 per ton. A system of stoping was employed which, however, seems to have been inadequate to meet the conditions there obtaining, as a few months since the stopes caved badly. The stopes were wide and all material was sent to the mill, sixty 950-lb. stamps handling an average of 240 tons per day. The mine was worked through an inclined shaft 1700 ft. deep.

At the Argonaut and Kennedy mines the operating costs are not made public. This is to be regretted, as both are under capable management and are at present the most successful mines on the Mother Lode. The Argonaut is worked through a 3800-ft. inclined shaft at about 60°; the Kennedy through a vertical shaft 3600 ft. deep. The stopes are as much as 20 ft. wide, the ground is very heavy, and considerable timber is required, the cost for timber being sometimes \$1 per ton or over, and the total operating cost is about \$3.50 per ton.

The main orebody of the Utica mine was from 40 to 120 ft. in thickness. The formation is amphibolite schist. On the foot-wall side it was talcose and often soft and wet for several feet. The hanging wall, which has a dip of about 80°, is generally solid, but at times great slabs break off. Square-sets were used and considerable timbering and filling with waste was necessary, though in some parts of the mine large stopes have stood open for years. The company owns water and power plants which also supply Angels Camp and vicinity. The profits from these add materially to the yearly income. While itemized costs are not available at the present writing, I have been informed that the total mining and milling costs at this mine approximate \$2 per ton, and that for several years past the mill has handled an average of 180,000 tons per year. A considerable amount of this ore comes from the Gold Cliff property of the company.

The Lightner mine, adjoining the Utica, and on the same vein, has a 60-stamp mill; 40 of the stamps are 950 lb., and 20 of 1000 lb. were added in 1908. The mill is operated by two 100-hp. direct-current electric motors. The cost of electricity is \$4.50 per horse-power-month; labor \$2.50 to \$3.75 for eight hours. The stopes were up to 50 ft. in width; the square-set method of timbering was followed. There was no water to contend with, as the lower workings of the Utica drained the mine. There were an average of 100 men employed, about 72 working in the mine. From 1908 to 1910 the total costs averaged \$2.56 per ton. This mine was taken over by a new company a few years ago, a new shaft was sunk in the hanging wall, and preparation made to extract ore in the upper workings, previously left behind on account of the poor condition of the old shaft. An interesting description, with costs of sinking the new shaft was given in the *Mining and Scientific Press*, February 4, 1911.

Several mines were operated near Graniteville, Nevada county, at low cost, but unfortunately, even with this advantage, few were successful on account of the low grade of ore handled.

At the Erie mine, from July 1, 1910, to January 1, 1911, 13,587 tons was treated at a total cost during that period of \$40,797.50, or a trifle over \$3 per ton, of which stoping and milling, including proportion of administration, are given as \$1.48. This has been described by S. H. Brocku-

nier.\* The main vein is wide and lies within slate. The ground was easily broken and conditions were favorable for low working costs. An adit 1700 ft. long was driven prior to the time of work described but the cost of this and of other previous development does not appear in the mining cost given. Power was derived from Pelton wheels at 330-ft. head at a cost of about \$4.50 per horse-power-month. The ore was crushed to 20-mesh. Several changes in working method were made, and for a short period, it is claimed, a working cost of \$1.29 obtained, but the mine soon afterward closed down. The Gaston mine is said to have had an operating cost ranging from about \$2.25 to \$3.50 per ton, depending upon the amount of development attempted during different periods of operation or charged to mining cost.

At the Trinity G. M. & R. company's property, near Carterville, Trinity county, some interesting costs have been obtained. The orebody occurs as an irregular sheet, from 25 to 80 ft. thick, dipping about 20° and covered by about 25 ft. of overburden. Hydraulic mining was used to strip part of this overburden. The ore is oxidized, soft, and friable, and is mined through glory-holes. Forty 1100-lb. stamps are operated by electric motors. The ore is crushed in cyanide solution to 30 mesh. The sand is leached, and the slime treated in Oliver filters. Two Merrill filter-presses are used for collecting the precipitate. The following is taken from the last annual report. During the first five months of 1911, there was mined and delivered to the crushing plant 15,995 tons of ore at a cost of 65c. per ton; during the following seven months 41,331 tons was delivered at a cost of 57c. per ton. The average value per ton was \$4.77, and extraction 80%; as this period represents about normal conditions the costs per ton are given in detail.

The mines in the Grass Valley district have narrow, rather flat veins, ranging from a few inches to several feet in width, the stopes averaging about 4 ft. though in some places the ground may be stoped 10 or even 15 ft. high. Mining costs are much higher than on the Mother Lode, and vary greatly at the different mines. This is partly due to the amount of development necessary to open up the orebody, and also, in some cases, to the method of bookkeeping employed and the amount charged against mining operations.

Mining costs are available at only one of the mines, the North Star, the management of which publishes reports annually. It is from the report for 1909 that some of the following figures are taken. During 1909, from the old workings of the North Star mine, 21,819 tons of ore was mined at an operating cost, including mining, milling, and proportion of general expense, of \$6.971 per ton; development work in the old part of the mine amounted to \$1.425 per ton, making a total cost of \$8.396 per ton of ore from the old workings above the 2700-ft. level. The lower workings, operated through the Central shaft, produced 69,791 tons at an operating cost of \$4.689 per ton and a development and exploration charge of \$1.114; or a total cost of \$5.803 per ton for the Central mine. Detailed costs for recent years at the Empire mine are not available. It is, however, generally supposed that total costs are a little in excess of \$5 per ton. Figures for this mine are taken from a report on working costs of the Witwatersrand by Ross E. Browne and are, I believe, exclusive of development charges. These

\**Eng. & Min. Jour.*, September 7, 1911.

figures can hardly be used for comparative purposes, but are given for such interest as they may have.

Mines in the Nevada City district are run at considerably lower cost than those at Grass Valley, partly on account of the veins being wider and also because the rock is more easily crushed. At the Ostemah mine, which has had a varied career, the mill during one period of operation crushed 5 to 6 tons per stamp in 24 hours, and the total

cost for mining and milling over a short period was somewhat under \$3 per ton. The mine was opened through an inclined shaft 900 ft. deep; the vein averaged about 3 ft. wide. I have considerable information on Grass Valley and Nevada City mines, which, unfortunately, I do not feel at

CYANIDE PLANT, EMPIRE MINE.

liberty to publish. The costs given, however, are representative. Accompanying this article is a table of operating costs of some Mother Lode mines.

MINERAL resources of the Madras district constitute an important factor in the wealth of the Indian Empire. Gold is mined extensively in the native states of Mysore and Hyderabad, the latter also producing coal in appreciable quantities. In parts of the Madras presidency manganese mines are operated. There are also deposits of magnesite, mica, graphite, steatite, and diamonds.

The total yield of the various gold mines of southern India in 1911 was valued at \$10,592,250, which represents an increase in value of half a million dollars during the past four years, according to a consular report. The aggregate ore reserves of the gold mines under operation at the close of the year was reported to be 1,991,679 tons. The record of the Mysore gold mine is remarkable. Since 1886 the company operating this mine has paid in dividends no less than \$32,319,000. In 1911 it produced gold valued at \$4,351,969, distributed \$1,778,760 to its shareholders, and placed \$194,400 to reserve. Its ore reserves at the close of the year amounted to 1,300,369 tons, besides an accumulation of 200,000 tons of tailing. The coal produced in 1911 was 447,943 tons, as compared with 460,988 in 1910. Practically all of the native coal of southern India is consumed by the local railroads. The output of the manganese mines in the district has steadily decreased during the past five years, the production in 1910 (the latest available figures) amounting to 46,441 tons, as against 125,820 tons in 1907. The output of mica during the past six years also shows a heavy general decline, for although there was a slight increase in the production in 1910 over that of the preceding year, the former amounted to only 191 tons, as compared with 1214 tons in 1906.

PETROLEUM has been discovered along the Tachin river, in Siam, according to a recent report, in the district north of Korat. It is said that the discovery was first made by some Laos villagers about five years ago, and these men have been utilizing the oil for their own needs and also selling it to neighboring villagers on a small scale. No attempt whatever has been made to bring up the petroleum in large quantities, the present method to draw out the oil being with long bamboos fixed together. A depth of 60 ft. is said to have been reached. The well is in an open glade of the forest, which thickly covers the whole of that part of the country. In its present crude state the oil smokes heavily when burned. The greatest drawback in development of this valuable find seems to be the situation of the well, about 200 miles from the nearest railway station. Reports of oil discoveries in the Siamese districts bordering upon Burma are also current, but have not been authenticated.

# Neutralization of Smelter Gases

By GEORGE C. WESTBY

\*The question of smelter fume treatment is one of commercial metallurgy, and the application of a panacea a question of dollars and cents. There have been many plans devised for quieting the complaints of injured agriculturists and others to whom smelter fume seems all that is evil, but too often the proposed plan has been merely mitigatory, or has neglected provision for a material return on the investment in the plant. In other cases the process is rendered inapplicable on account of limited demand for the output whose production and sale is the vital commercial feature.

Of the methods proposed for treating smelter fume in an economic way, this article is limited to consideration of methods with which I have experimented. The first of these was developed during 1902-1903 and consisted of a process for producing liquid  $\text{SO}_2$  from the fume, utilizing the heat of the fume by means of economizers and air-heaters. The  $\text{SO}_2$  was to be liquefied by an ice or refrigerating machine, with the crystalhydrate of  $\text{SO}_2$  as an intermediary product. Aside from the mechanical difficulties incident to the arrangements for removing the flue-dust, the crucial objection advanced against the process was the lack of a market for the liquid gas as produced at the rate of thousands of tons per day. The suggestion that it could be used as a refrigerant in place of ice in freight cars, and in the small ice-boxes of private homes, seemed inadequate in face of the fact that the market was both problematic and undeveloped, while awaiting the expenditure of some millions of dollars in providing the necessary equipment.<sup>1</sup>

During the course of further work in connection with the fume problem, the idea suggested itself that the sulphurous gases might be bound with the bases of slag and thus reduced to a more controllable form. Experiment demonstrated that the idea might be practically applied, and also suggested the general method of fume treatment which consists in the neutralization of acid fumes on slag, and ensuing precipitation of the toxic oxides in ponds or other limited areas on the earth, chiefly as harmless and insoluble compounds with iron and other bases of the slag. As developed, the process also involved the recovery of the metal carried away in slag and flue-dust.

The fact that chilled, finely divided slag very rapidly dissolves in hot dilute solutions of  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , is generally known to metallurgists and chemists, and they are also acquainted with the fact that the silicic acid is retained in apparent solution. Experiment proved that hot solutions of  $\text{SO}_2$  are also capable of effecting the dissolution of the slag in the same way; this discovery became the basis of our attack on the smoke difficulty.

In carrying out the process the materials at command are a hot acid smoke, laden with flue-dust, vapors, or sulphur, and possibly arsenous or other volatilized compounds, and granulated chilled slag. The acid gas is an immediately available and intensely active chemical agent, but the granulated slag, while susceptible to the vigorous attack of the sulphurous reagent, is preferably finely ground in order to accelerate its solution and incidentally reduce the size of apparatus required in its treatment. In conjunction with the smoke and slag, water, or circulating ferruginous smoke liquor is necessarily used as a medium of chemical translation, in maintaining suspension of the slag pulp and in carrying the compounds formed. The slag and smoke are brought together by means of an apparatus which is introduced as a part of the flue systems. The province of the appliance is the retention of a vast surface of wetted slag in the direct path of the smoke current, in such a way that

the smoke, slag, dust, steam, and water become as nearly as possible a hot homogeneous mist.

Chemical action under such circumstances is essentially rapid, and ensures the absorption of the sulphurous gases without recourse to unwieldy apparatus or large chambers. The result of the combination of the constituents of the mixture is the production of ferrous and ferric sulphite, ferrous sulphate, various thionates of iron, and in a smaller degree sulphur salts of other bases. The copper is mainly present in the matte particles contained in the slag, and when ground slag is used in the apparatus, remains for the most part undissolved. That portion of the copper taken in solution may be re-precipitated in the absorber by the action of polythionates developed in the smoke liquor through the interaction of the  $\text{SO}_2$ , sulphites, and free sulphur in the smoke.

In many of our experiments copper was obtained principally in an oxidized form by blowing molten slag into slag wool. In these cases the copper was maintained in solution and after discharge from the absorber was precipitated in a wooden tank by heating the solution with steam to about  $80^\circ\text{C}$ . The development of thionates, on which the precipitation of part of the copper depends, requires no attention under the usual circumstances attending the roasting of ore. Their formation is encouraged in the presence of the sublimed sulphur of the smoke, and by the sulphites and the excess  $\text{SO}_2$  of the smoke liquors. During the course of their production there may be a constant representation of all those compounds designated as polythionates, but the dominance of any particular form depends on the chemical and physical characteristics of the smoke, the liquor, and the material treated. The thionates produced are ephemeral and finally break up into sulphates, sulphur dioxide, and free sulphur, as indicated in the following equation:

To illustrate a possible set of conditions occurring in the absorber during treatment of the smoke, we may take the following successive reactions:

When sodium and potassium are present in the slag they are dissolved with the other constituents and later appear as sulphates in the discharged smoke liquors, and may be recovered if desired from the residues of the evaporated liquor. Zinc, if present, is similarly dissolved and may be separated from other residues by volatilization or any practicable means. Lead, silver, and gold are retained undissolved with the precipitated copper. In some cases green vitriol would be an important and valuable by-product.

The liquor produced in the absorption chamber may be again used or it may be continuously discharged on waste land, over which it spreads in a thin sheet that will rapidly evaporate under the influence of wind and sun. In the latter case, oxidation and hydrolysis form an insoluble basic sulphate, by translation of the green vitriol in general accordance with the equation

At the same time deposition occurs of the silicic acid and of sulphur arising from the decomposition of thionates.

Generally the liquor issuing from the absorber contains only very limited quantities of free acid. If, however, any objectionable amount of acid is present, it may be neutralized by passing the liquor over slag or through calcareous or soluble ferruginous material. In some cases the percolation of the liquor into calcareous soil would not be objectionable, as the comparatively small quantity of acid would be effectually neutralized in the formation of insoluble calcium sulphate, and thus the liquor could

\*From *The Journal of Industrial and Engineering Chemistry*.

<sup>1</sup>This phase of the control of smelter fume was independently developed by F. R. Carpenter, of Denver.

not seriously affect the ground-water. The flue-dust carried by the smoke is effectually caught by the somewhat glutinous slag particles, and remains with the residues of the reaction chamber.

In carrying out the experiments it was recognized that the development of a simple apparatus was of the first importance; accordingly much time was spent on different tentative designs, but the aim in each case was the form of apparatus which would require the minimum of attention, repairs, and adjustment. The arrangements tried were of two general forms: a tower or vertical chamber and a horizontal rotary apparatus.

The vertical arrangement consisted generally of a wooden tower, provided with a large number of narrow staggered shelves. These pieces were set three or four inches apart, from one end of the tower to the other. A hopper was introduced at the top of the tower for the reception of the slag and water used in the treatment. The bottom of the tower was arranged to permit the formation of a hydraulic seal at the discharge. At each end of the tower pipes were inserted; one of these was connected directly with the flue of a furnace and the other with a fan.

In operation the wet slag was charged into the hopper and was discharged from the hopper by gravity to the shelves. From the top shelves the material spread over the cross-section of the tower and by the action of the series of staggered shelves, fell in splashing cascades to the bottom of the tower, coming in contact throughout its course with the hot current of acid smoke drawn through the apparatus by means of the fan. The liquor derived by the action of the smoke on the wet slag discharged through the hydraulic seal to a large wooden tank in which the copper was precipitated by means of steam. Wooden launders conveyed the residual liquor to a pond.

The horizontal rotary apparatus was cylindrical in form. Shelves or projections were set at intervals along the interior surface, so as to lift the mixture of slag and liquor and drop it in sheets through the gas current in the apparatus. The shelves were set at different angles so that the material would be distributed along the different planes during rotation of the cylinder. The splashing on the sides and bottom of the apparatus caused by the falling material aided in filling the whole of the cylinder with a constant spray of absorbent mixture.

The cylinder rotated about short pipes of comparatively large diameter; these were set at the smoke entry and exit ends of the cylinder and were connected respectively with the flue of the furnace and the intake of an induction fan. The treated smoke was discharged through the fan. Means were provided for continuously feeding the absorbent material into the cylinder, and a pump with a siphon attachment was used in removing the exhausted liquor. The first general test was made with a rotating cylinder. The cylinder was about 10 ft. long and 30 inches in diameter. The results of one of the experiments with the apparatus are given below:

	Time: 10:15	10:45	11:00	11:15
Temp. gas inlet °F.....	215°	220°	210°	242°
Temp. gas outlet °F.....	82°	84°	74°	74°
Temp. water inlet °F.....	64°	65°	65°	65°
Temp. liquor outlet °F.....	90°	100°	78°	86°
Cu. ft. gas per min. measured				
at intake .....	34.2	32.4	33.0	44.4
Per cent SO <sub>2</sub> inlet.....	4.9	4.7	5.4	4.7
Per cent SO <sub>2</sub> outlet.....	1.9	1.0	0.85	2.7
Absorption in 10 ft., per cent.	61.2	78.8	84.2	42.5

Note.—140 lb. of slag charged at beginning of test; none charged during interval between 10:45 to 11:15.

The test gives results better than average, consequent on treatment of smaller volume of smoke per second than ordinary. The test illustrates a set of experiments where the slag was not fed continuously, but was charged in one mass. The absorption in this case steadily increased for a short period after charging, then fell off rather rap-

idly. In the experiment given above, the drop is accentuated by the increase in gas current.

In the experimental results given below, the slag was practically continuously charged, although not in sufficient quantity to bring about complete absorption. The tests were made with the tower apparatus of which the general principles have been described. Two towers were used connected at their tops. The total length of the apparatus was 77 ft. The cross-section was 4 square feet.

The analysis of the solutions of the set of experiments, of which the above is an example, varied with the relative quantities of slag and water charged, the rate of smoke supply, and to a large extent depended also on the temperature of the gases. The constituents of the solutions varied between the following figures:

	Minimum,	Maximum,
	%	%
Fe .....	0.54	3.0
S .....	0.49	2.9
Cu .....	0.00	0.8
SiO <sub>2</sub> .....	..	3.2

The average temperature of the incoming smoke was 393°F. and that of the discharged gases 92°F. Throughout the series the volume of smoke treated varied between 90 and 235 cu. ft. per minute. On the whole, these tests were the most satisfactory, as no trouble was experienced with the apparatus or in the introduction and application of different conditions.

Succeeding the experiments described, tests were begun for the treatment of 5000 cu. ft. per minute of smoke assaying 4.5% SO<sub>2</sub>, a volume representing the total gases discharged per minute from a 35 to 40-ton McDougall roaster. The apparatus used consisted of a rotating cylinder 36 ft. long and 12 ft. in diameter, arranged as previously described. On account of an underestimate of the charge to be carried, the foundations, running equipment, and apparatus generally were designed to sustain only a fraction of the slag and water charge necessary to absorb all of the SO<sub>2</sub> in the smoke; our absorptions were therefore seldom greater than 45 to 55% of the SO<sub>2</sub> in the smoke. For brief periods in one case absorptions of 92% and 100% were secured. A satisfactory degree of elimination of the SO<sub>2</sub> from the smoke was never approached, except at the expense of a break-down with this particular apparatus. The results obtained, however, were valuable as the basis for a successful design for a cylindrical apparatus.

A study of the set of results given below will show the trend of the experiments and also make clear the limitations of the apparatus used, when it is understood that the entry 'Period of run, minutes' implies 'Period of anxiety before smash-up, minutes.' The entry 'Slag required, theoretical' is a factor derived from the analysis

of the solution, in consideration of the ratio of iron dissolved to sulphur absorbed. The weight of iron dissolved is multiplied by 2.7, a constant derived from the fact that the weight of slag was approximately equivalent to 2.7 times the weight of iron contained in the slag treated. 'Slag required' represents the quantity of slag which would be required per minute, to exactly neutralize the weight of  $\text{SO}_2$  driven from the furnace per minute. It is obvious that in practice the mere presence of this computed amount would be altogether inadequate to actually neutralize the  $\text{SO}_2$  given off minute by minute from the furnace, since the whole of the mass is not instantaneously acted on. Depending on the degree of subdivision, the constitution of the slag and other physical and mechanical factors, a slag excess of 3000 to 10,000% is requisite to effect a complete elimination of the  $\text{SO}_2$  from the smoke.

Mg. Cu per 100 c.c. sol....	21.4	10.5	15.0	15.0	9.1

By comparison of the data it is seen that the absorption of  $\text{SO}_2$  tends to rise as the rate of charging slag is increased. Consideration of 2 and 5 would suggest also that the absorption rises with the temperature; this indication is confirmed in other experiments not given here. In 1 the temperature is low and the absorption high; this is probably due to the high rate of water supply combined with the comparatively high rate at which the slag wool is charged.

In order to determine the practical effect of maintaining the slag excess, which had been deduced as the necessary amount to insure complete absorption of all the  $\text{SO}_2$  discharged from the furnace during any period, a cylinder experiment was made by introducing 1500 lb. of slag wool before starting operation. The results were as follows (period of run, 10 minutes, 300 lb. of slag added during run):

Rate of adding slag, lb. per min.....	180*
Water supplied per minute, lb.....	1195
$\text{SO}_2$ absorbed, per cent.....	100
Milligrams Fe in 100 c.c. solution.....	1260
Milligrams S in 100 c.c. solution.....	1050

\*Comparative.

After ten minutes the apparatus was stopped, measurements made, and samples taken. Five minutes later the apparatus was again started and operated 15 minutes, a stop being necessary at the end of that time on account of the great weight accumulated in the apparatus—principally liquor in excess of the pump capacity. The result at the end of the second period was (period of run, 15 minutes):

Rate of adding wool, lb. per min.....	100
Rate of adding water, lb. per min.....	1001
$\text{SO}_2$ absorbed, per cent.....	90.2
Milligrams Fe per 100 c.c.....	908
Milligrams S per 100 c.c.....	1036

The experiments stopped short of a commercial realization of the process, due to circumstances not affecting the

question of  $\text{SO}_2$  elimination. However, the net results of the work sufficiently established the following facts:

(1) The acid gases of smelter fume can be effectively neutralized by means of chilled slag, with the complete elimination of flue-dust from the discharge.

(2) The toxic action of the smelter vapors and gases can be controlled by converting them into constituents of harmless compounds and causing their deposit in an insoluble form on waste land.

(3) In bringing about the control of the gases in the manner stated, it is both feasible and desirable to recover copper, lead, and other metals contained in the slag and in the fume.

(4) The conservation of by-products such as green vitriol, potash and soda salts, and silicic acid is possible where markets for the material are not too far removed from the smelting plant.

(5) The indirect use of sulphurous fume in the treatment of slime and tailing waste from the concentrator is sometimes feasible. The reaction given below will suggest general procedure:

## Mineral Resources of the Copper River Basin

The search for gold and copper which began in the mountains south of Chitina river, Alaska, with the rush of prospectors to the Copper River basin in 1898 has been carried on spasmodically since that time. As a result copper was found in the mountains east of Taral during the first summer, and the gold placers of Bremner river were discovered a few years later. No copper has yet been produced in this district, according to the United States Geological Survey, but the facilities for transportation offered by the Copper River & Northwestern railway during the past year have stimulated interest in the development of copper properties, so that considerable prospecting has been carried on.

One small stream, Golconda creek, a tributary of Bremner river, has yielded most of the gold so far produced in this district, although Little Bremner river has contributed a part. Gold in commercial quantities has not been found near Taral nor between the Chitina and the Bremner in Hanagita valley. The total production of the district is not known, but several thousand dollars' worth of gold has been produced each year since mining began. The high cost of supplies and difficulty of access have done much to discourage prospectors.

All the gold so far produced in the Bremner River valley has been obtained from stream gravels. This valley is practically unprospected, so far as lode deposits are concerned. The three parts of the valley of present or prospective importance because of known placer-gold deposits are Golconda creek, Little Bremner river, and the lower part of Bremner above the Little Bremner. The geology of the region so far as known and the prospects for the development of gold in the Bremner River valley, on Golconda creek, and on Little Bremner river are described in *Bulletin 520-C* of the United States Geological Survey, which also discusses the character of the copper deposits in the mountains between Canyon creek and Chitina river.

MEMBERSHIP in the Mining and Metallurgical Club of London has increased to 921, of whom 700 are mining engineers, the average daily attendance at the Club, which is in the heart of the business district, being 200. The initiation fee is \$15 and the yearly dues \$15. Visitors are allowed the privileges of the Club for two weeks and can continue thereafter by the payment of small monthly dues. The gross receipts from the dining room for the year were over \$16,000, and the surplus of total income over expenditures for the year 1911-12 is about \$7000.

## Reclaiming Dredged Land

By J. H. LEGGETT

\*From certain results observed on land that had been reclaimed following hydraulic operation during the eighties and early nineties, I concluded that dredged land could also be restored. When I began dredging my farm in 1902 I planned to test out my belief that the land would again produce. During the season 1903 and 1904 I planted some small eucalyptus trees and black figs on unleveled dredged land. These did surprisingly well, and the eucalyptus are now 50 ft. high and 12 in. through at the base. The figs are lost in the jungle. That season alfalfa, blackberry, bamboo, and Johnson grass roots went through the dredges

EUCALYPTUS GROVE ON DREDGE TAILING.

and grew of their own accord luxuriantly in the hills and hollows of the debris. These bunches of alfalfa are 3 ft. high by February 1 of each year.

Being very busy with my dredging interests it was not until the season of 1907 and 1908 that I did any regular planting except eucalyptus, of which I have a forest. That season I leveled off with scrapers 10 acres and planted it to grapes, peaches, apples, pears, apricots, walnuts, chestnuts, pomegranates, and oranges. I put no soil on the land except a three-gallon bucketful of earth in the hole with each tree or vine, and covering it up with clean cobbles. Fertilizing is all that is necessary. I watered the trees first planted a few times with a hose, but found this unnecessary if I planted them deep enough. With vines, a long cutting planted with a crowbar is the best method, and no further attention is necessary, except fertilizing and pruning. The gravel is at all times damp at 2 ft. in depth, and turning over loose cobbles will not accomplish much as cultivation. Grapes, peaches, apricots, and cherries proved a

great success. Apples, pears, and oranges made no headway, but might with deep planting.

It was not until last summer that it dawned upon me that the venture was a commercial success. The grapes and peaches then yielded wonderfully. I did not ship any then, as the local market took them quickly at high prices, as they were in the market ahead of any other products of a similar variety. I noticed that my Tokay, Muscat, and black grapes were ready before the first crates were shipped from Vacaville, so this season I made arrangements to beat them to it, with the following result.

From ten vines of Tokay grapes planted 1908, I picked 9 crates which yielded a net profit of \$9.98. The Muscat grapes, of which I had several hundred crates, I chiefly sold locally at 4c. per pound, but have sold about 100 crates in San Francisco at 85 and 90c. per crate. I should have

GROWING GRAPES ON COBBLES.

shipped them two weeks earlier, but it did not dawn upon me how many I had until about August 15.

In 1909 I sold to the Natomas rock crushing plant the gravel and cobbles on 165 acres, of which the company has cleared off about 15 acres, and now is making great headway owing to large demand and the building of the state highway, which will quickly absorb all of the cobbles on my land. About four feet of cobbles is left above the sand and soil, which is ideal for planting, and this is where I will do my greatest development. I expect to plant 20,000 vines and cuttings this winter, and follow the steam-shovels as they proceed in the future. The acreage that I leveled originally I will work entirely into grapes.

Two years ago my Tokay grapes were colored on July 10, but last year and this year have been late, the season attended by cloudiness until June 20. One reason that this fruit is earlier is that it starts to grow two weeks before similar products on natural soil, and it is not until mid-winter that the leaves are frozen. Frank B. McKevitt, manager of the fruit company, says that my Muscat grapes are two weeks ahead of those from Vacaville, that their

\*Excerpt from the *Pacific Rural Press*.

quality makes a prime shipper of them, and advises me to plant them largely.

Contrary to what might be expected, these vines are extremely vigorous, and bear second and third crops. The older vines cover a space 16 ft. square. All diseases and blight I used to be troubled with prior to dredging seem to have disappeared. This coming season I plan to plant cucumbers and early tomatoes.

I am still learning, but have reached that point where I know that the thing to do is to go ahead and plant. The details of the best way to train the vines I will work out in the future. They may do better on trellises, but they are doing well with common pruning, and Muscat grapes are particularly fine where they spread flat on the rocks. I could write much more on this subject, but no one will believe what I have written. When I get a few hundred miles away, I question whether it is so myself. I know why the cobbles are productive, as I have been through a course of 25 years observation, but I cannot make others see, in a little while, what it has taken me so long to absorb.

## Metallic Minerals of Brazil

The total output of gold in Brazil since the colonization of the country up to the present time has been estimated as reaching 700,000 kg., according to a correspondent of the *London Times*. About nine years ago the government granted a series of concessions for the exploration of a number of river beds for gold and other minerals. Gold has been found in the states of Minas Geraes, Goyaz, Matto Grosso, Bahia, São Paulo, Rio Grande do Sul, Maranhão, and elsewhere. It has been traced to three mountain ranges, extending parallel to the coast. The Mantiqueira range, an offshoot of which, the Espinhaço, contains the most important of the gold-mine workings; the mountains between the rivers São Francisco and La Plata, and the mountains bounding the river valleys of the Paraguay and Paraguay. Gold deposits are found in pyrite veins, quartz, and itabirite; the last is not known outside of Brazil. Alluvial gold is found along the rivers.

Low-grade gold ores have in some cases been very skillfully treated in Brazil. The Ouro Preto gold mine may be instanced. The ore is composed of quartz, tourmaline, arsenopyrite, and iron pyrite, with some bismuth. The pyrite content varies from 4 to 6%; pieces up to 5 gm. in weight have been found, which are, however, exceptional. The size of the particles of free gold present in the ore may be inferred from the fact that 5% remains on a 40-mesh sieve, and 45% on a 100-mesh, the remainder passing through. The presence of bismuth with the gold caused difficulties, which were successfully surmounted. Water supply was obtained from a source six miles away, with a fall of 350 ft., the supply varying from 1300 to 1500 ft. per minute. The mine was planned with several inclined shafts, radiating from a centre like the spokes of a wheel, with lines of rails in each.

It has been reported that quicksilver has been found along the valley of the Tripuby river; cinnabar-bearing lodes in coarse, more or less porous, sandstone have been discovered, but have not been sufficiently developed to enable experts to state whether they can be profitably worked. Traces of platinum have been found in deposits of the Candado river, but the parent rock has not yet been traced. Even in the Urals, from which the world's main supply is obtained, the weight of platinum per ton of deposit is extremely small, and deposits along the Candado river containing a larger percentage than those hitherto known will have to be found before the platinum industry can be made a profitable one. The present price, however, is so high, and it is so obvious that the supply is not equal to the demand, that a vigorous search of the river beds might repay the cost of exploration. Last year the price per ounce rose from £7 12s. 6d. in January to £10 in December, and it has practically kept to that level all through this year, so that there is every inducement to follow up the traces, which may point to richer deposits.

Minas Geraes also contains deposits of lead ore, which are likewise found in São Paulo and Rio Grande do Sul. Within the last few years the output of manganese ore has very considerably increased; important centres are Miguel Burnier and Queluz, where mining operations were commenced about eighteen years ago. At the latter centre there are now five works. The ores mined there are made up of the following component parts: metallic manganese, approximately 52%; iron, 3%, with smaller percentages of silicon and phosphorus. At one of the works at Queluz the output reaches 600,000 tons per year. The known supply may last for several generations. Considerable quantities of manganese ore are shipped to England during recent years, as follows:

		Value.	Cost.
	Tons.	£	£ s. d.
1907 .....	72,200	192,100	2 13 3
1908 .....	56,900	120,000	2 2 1
1909 .....	69,900	126,600	1 16 0
1910 .....	80,000	156,600	1 19 0
1911 .....	71,200	139,600	1 19 1

Copper is known to occur in at least seven states. The most important mines are situated at Camaquã, where the ore contains over 50% of copper. Four lodes are now being worked by means of adits; their thickness averages four feet. The richest portions of the ore are shipped and the rest smelted locally to matte containing 50 to 60% of copper. Elsewhere sulphide ores are worked and deposits have been opened in the states of Bahia, Ceará, and Maranhão.

## Extraction of Tin from Ores

By EDWARD WALKER

The pioneer of chemical extraction of tin from ore and tailing is Arthur Richards, whose work is deservedly attracting the attention of everyone connected with Cornwall or with tin mining in other countries. He adds a small percentage of common salt and coal to the finely ground material and treats the mixture in a furnace at a bright cherry-red heat. The effect is to volatilize the tin as fume, consisting chiefly of chloride. His experiments have shown that practically the whole of the tin as estimated by chemical assay can be removed in this way, for his residues never contain more than ½ lb. of metallic tin per ton. The cost of the operation is not expected to be greater than that of water-concentration, that is to say, 4 to 5 shillings per ton of ore. As regards the subsequent treatment of the tin fume, in all probability the electrolytic method will prove the most suitable. The cost of this method does not count in the same way with a high-priced metal like tin as it does with lead or zinc.

Whenever a new method for the commercial beneficiation of ores is introduced, it is inevitable that some one will bring forward past instances. Thus we shall probably hear of the work done by the Metals Volatilization Co. in Colorado ten years ago, where a somewhat similar idea was applied to the extraction of copper. Also, the old process for extracting the tin present in silicate slag by means of calcium chloride may be adduced as an anticipation. From the point of view of the latter process, it may be advisable to mention that a chloride does not react directly upon tin oxide to produce tin chloride; but that the presence of silica is necessary. Mr. Richards has this fact in view when he mentions in his specifications that the process is only intended for low-grade ores, and that if a high-grade ore or concentrate is to be treated it must be mixed with low-grade ore, or have some sand or silica added to it. I ought to mention also that other metallurgists in Cornwall are experimenting on chemical methods of extraction. Their investigations have not progressed sufficiently to warrant the publication of details. The high price of tin and its steady demand in the tin-plate industry serve to stimulate research for better methods of its recovery from its ores.

# Copper Production of Arizona

By B. S. BUTLER

\*Arizona produced 303,202,532 lb. of blister copper in 1911, as compared with 297,250,538 lb. in 1910. This is the largest output in the history of the state and continues Arizona in first place among the copper-producing states. The steady output of copper from Arizona began about 1875, though there was intermittent production prior to that date, the earliest record of production being for 1862. Since 1880 the growth of the industry has been steady and rapid. To the close of 1911 Arizona had a recorded production of 3,494,333,111 lb. of copper, or 21.38% of the total output of the country, thus giving the state third rank among the copper-producing states. Arizona produced 27.63% of the total output of the country for 1911. Nine copper-smelting plants operated within the state during the year. The greater part of the production was from five districts.

## BISBEE DISTRICT

The Bisbee or Warren district, in southern Cochise county, was the largest producer, with about 130,200,000 lb. of

ground open for a long period is prohibitive. The quantity of ore actually blocked out in proportion to the annual output of copper is probably as small for this district as for any large producing district in the country. Most of the ore occurs in irregular bodies without definite arrangement, so that the cost of prospecting is greater than in many other districts. Moreover, the soft heavy ground associated with the ore makes it necessary to employ the square-set method in mining, and the cost of timber adds materially to the cost of mining. Recently efforts have been made by both of the principal companies to modify their system of mining so as to use less timber. The cost of mining in the district, however, is likely to remain relatively high. Centralization and improvement in the hauling and hoisting systems of the mines has resulted in marked economy. The ores of the district continue to show a decrease in grade, but this is in part due to improvement in mining and metallurgical methods which permit the treatment of lower-grade material. It is the policy of most of the companies to mine as low-grade ore as can

MINES AT BISBEE, ARIZONA.

blister copper, as compared with 142,500,000 lb. in 1910. Production in the district began in 1880, since which time it has been a constant and increasingly important contributor to the output of copper. To the close of 1911 it had produced 1,415,200,000 lb. of copper, or 8.64% of the output of the United States and 40.3% of the Arizona production. In total and in present output it ranks third among the copper districts of the country.

In the early days the output of copper was entirely from oxidized ores, but in recent years the quantity derived from sulphide ores has rapidly increased, and at the present time probably equals that derived from oxidized ores. It is reported by the companies that additions of ore reserves in all the properties have fully equaled or exceeded extraction and in some cases important developments have been made. In the Oliver shaft new oxide orebodies were found on the 1050 and 1250-ft. levels, and new sulphide bodies on the 1250 and 1600-ft. levels. Large bodies of iron pyrite assaying from 2 to 4% copper have been developed in the Briggs shaft, together with smaller bodies of higher grade ore. An especially interesting development in the Copper Queen mine was the discovery, in the Spray division of the mine, of sulphide ore in the Abrigo limestone of Cambrian age. Previously ore had not been developed at so low a geological horizon. Another discovery that may prove of importance is the occurrence of disseminated chalcocite ores in the porphyry of Sacramento mountain. The Shattuck-Arizona company also reports the development of important orebodies.

The nature of the deposits of the district do not favor the blocking out of extensive ore reserves far in advance of immediate needs, since the cost of keeping the heavy

be treated at a reasonable profit. In the early days of mining in the district the oxidized ores yielded about 20% of copper. For 1911 the average recovery was about 5.9% copper, with 0.0308 oz. gold and 1.49 oz. silver per ton, an average precious-metal content of \$1.42 per ton of ore.

The Copper Queen mine produced a total of 619,132 tons of ore and precipitate, containing 74,489,728 lb. of copper, 16,895 oz. of gold, and 1,227,453 oz. of silver.

The Calumet & Arizona Mining Co. produced 21,476,739 lb. of copper, 216,987 oz. of silver, and 9329 oz. of gold. The average net cost per pound of refined copper produced was 8.33c. The following table shows the grade of ores.

Operations of the Calumet & Arizona Mining Co. in 1911:

	Dry Wt.
Tons ore mined (including fluxing ore).....	244,067
Tons ore shipped (including fluxing ore).....	244,772
Tons ore smelted (not including fluxing ore)....	212,370
Tons fluxing ore smelted .....	38,831
Pounds copper recovered per ton ore.....	97.677
Pounds copper recovered per ton fluxing ore....	13.400
Per cent copper recovered per ton ore.....	4.884

The Superior & Pittsburg Mining Co. produced 28,469,166 lb. of copper, 236,960 oz. of silver, and 8785 oz. of gold. The net cost per pound of refined copper produced was 6.60c. The grade of the ore is shown in the following table.

Operations of the Superior & Pittsburg Mining Co. in 1911:

	Dry Wt.
Tons of ore mined .....	205,603
Tons of ore shipped .....	205,675
Tons of ore smelted .....	206,234
Pounds of copper recovered per ton.....	138.348
Per cent of copper recovered.....	6.9174

\*From an advance chapter, 'Mineral Resources of the United States, 1911.'

From August 1, 1910, to June 9, 1911, the Shattuck-Arizona Mining Co. shipped 32,029 tons of ore averaging 12.85% copper. Shipments were discontinued on June 9. At Douglas the smelting plants of the Copper Queen Consolidated Mining Co. and the Calumet & Arizona Co. were operated throughout the year. The Copper Queen Consolidated Mining Co. had in process the construction of an addition to the smelter to consist of a calcining and reverberatory plant to treat fine ores, concentrate, and flue-dust. It will consist of two reverberatory-furnaces and six calciners of the McDougall type, with the necessary concentrate-bins, dust-chamber flues, and stacks. These additions will be completed in 1912. In 1911, in addition to Copper Queen ores, the smelter treated the ore and concentrate of the Moctezuma Copper Co. of Mexico, and custom ores from Arizona and New Mexico. The Calumet & Arizona Mining Co. completed plans for and began construction of a new smelting plant, which it is expected will be ready for operation by August 1913. The plans contemplate a complete custom sampling mill; Cananea bedding system, 58,000 tons capacity; two 48-in. by 40-ft. blast-furnaces; dust-chamber 60 by 180 ft.; steel stack lined with acid-proof tiling 350 by 25 ft. in diameter; four 19 by 100-ft. reverberatories, with foundation and building for a fifth; twelve 21-ft. Herreshoff roasting-furnaces and suitable dust chamber; and six Great Falls converters 12 ft. in diameter. The district is served by the El Paso & Southwestern railroad. Oil for fuel is used extensively in the production of power, which is generated in central plants and distributed to the points where needed. Early in 1911 a merger of the Calumet & Arizona and Superior & Pittsburg Mining companies was effected. The stock of the Calumet & Arizona Mining Co. was increased to 650,000 shares and an exchange made for the stock of the Superior & Pittsburg Mining Co. on the basis of 1 share of Calumet & Arizona for  $3\frac{1}{2}$  shares of Superior & Pittsburg.

#### MORENCI-METCALF DISTRICT

The deposits of the Morenci-Metcalf district are at Morenci and Metcalf, in Greenlee county. During 1911 the district produced 71,500,000 lb. of blister copper, as compared with about 73,154,000 lb. in 1910. The district was one of the earliest copper producers in the state, the output beginning as early as 1873, and since 1880 it has been an important contributor to the copper output of the country. To the close of 1911 a total of 954,200,000 lb. of copper had been produced, or 5.82% of the output of the country since 1845, and 27.2% of the output of the state. In total production it ranks fourth among the copper districts of the country and second in the state; in the output for 1911 it ranks fifth in the country and second in the state.

The copper ores<sup>1</sup> of this district occur as contact deposits in Paleozoic limestones and shales which have been intruded by stocks and dikes of porphyry, as disseminated deposits mainly in the porphyry, and as deposits in fault fissures of the Coronado type. The original ores were pyrite and chalcopyrite of too low grade to be of economic importance. The workable bodies have resulted from the process of secondary enrichment. The orebodies in the limestone were formed in certain beds favorable to deposition, and this produced roughly tabular bodies nearly parallel to the stratification of the limestone. Alteration of these bodies has produced oxidized ores which formed most of the workable bodies in the limestone. These are now nearly exhausted. The disseminated ores occur in highly altered porphyry adjacent to fissure veins. The copper content of the upper portion of these deposits has been leached and deposited as chalcocite on the pyrite lower down. This has produced a zone of commercial ore

varying in thickness, in general not extending below a depth of 400 ft. In the fault fissure or Coronado type of deposit commercial ore has been developed to much greater depth, and recent exploration of the principal faults in Copper mountain has shown that commercial ore occurs associated with these faults considerably below the general level of the ore-zone.

Of the 1911 copper output, 54,000,000 lb. was derived from concentrating ores and 17,500,000 lb. from smelting ores. The mines of the district produced 1,323,447 tons of concentrating ores, yielding 2.01% copper, and 222,551 tons of smelting ore yielding an average of 4% copper, the average yield for the 1,545,998 tons of ore produced in the district being 2.29%. The ores in general have a low gold and silver content, and as much of the copper is of sufficient purity for commercial purposes it is not refined electrolytically, and consequently the precious-metal content is not recovered. Until recently the square-set and fill system of mining which necessitated the use of large amounts of timber was very generally employed in the district. More lately modified systems of slicing and caving have been introduced and are being extended, so that at present a large percentage of the ore is extracted by these methods at a considerably reduced cost. The district contains large reserves of ores, and developments during 1911 have fully maintained the reserves and added to the possibilities of ore in both the Morenci and the Metcalf sections of the district. The Detroit Copper Co. reduced to bullion 517,087 tons of ore, yielding 22,704,398 lb. of copper, or an average of 45.9 lb. of copper per ton of ore treated. The following tables show the results of operations at the mill and smelter.

Concentrator operations of Detroit Copper Co. in 1911:

Ore concentrated, tons .....	500,000
Percentage of copper in ore .....	2.869
Concentrate produced, tons .....	66,012.14
Percentage of copper in concentrate .....	15.876
Saving .....	73.05
Tailing assay .....	0.848
Tons ore milled per ton of concentrate .....	7.57
Water used per ton ore milled, gallons .....	522.6

Statement of ores completely reduced to bullion during the year, the original assay, and the yield of same, by the Detroit Copper Mining Co., in 1911:

	Ore treated to bullion, short tons .....	Bullion produced, lb. ....	Copper assay of original ore, % .....	Copper bullion per ton of ore, % .....
Concentrating ore .....	500,379	19,429,038	2.866	1.941
Smelting ore .....	6,678.3	2,083,680	16.846	15.598
Silicious ores to converters .....	9,096	968,520	5.749	5.323
Total Detroit Copper M. Co. ores treated at Morenci .....	516,153.3	22,481,238	3.098	2.179
Purchased ores treated at Morenci .....	933.5	223,100	12.909	11.953
Grand total .....	517,086.8	22,704,398	3.116	2.195

During the fiscal year ended September 30, 1911, the Arizona Copper Co., Ltd., produced 34,584,000 lb. of copper. The company's mines produced 741,746 dry tons. The average yield in copper per ton of ore treated was 46.4 lb., or 2.32%. This compares with a yield of 2.13% for the preceding year. Of the total ore, 94% was concentrating ore and 6% smelting ore. Of the total copper production, 82% was derived from sulphide ores and 18%

<sup>1</sup>For detailed report of the Clifton-Morenci district see Lindgren, W., 'The Copper Deposits of the Clifton-Morenci District, Arizona,' *Prof. Paper U. S. Geol. Surv. No. 43*, 1905; Tovote, Wm. L., *Mining and Scientific Press*, Vol. 101, 1910, p. 770.

from oxidized ores. During the latter part of the year plans were made for beginning the construction of a new smelting plant to replace the present one, which has become out of date. For the fiscal year ended August 31, 1911, the smelter of the Shannon Copper Co. produced 14,944,933 lb. of copper from company ores and 223,169 lb. from custom ores. During the same period the mines of the company yielded 263,975 tons of ore, with an average extraction of 56.9 lb. per ton. The average cost per pound of copper for the year was 11.5c. The district is served by the line of the Arizona & New Mexico Railway Co. A narrow-gauge line extends from Morenci to connect with the Arizona & New Mexico railway at Coronado. Early in 1910 the Shannon Copper Co. completed a standard-gauge road connecting the mines at Metcalf with the concentrating and smelting works at Clifton.

#### JEROME DISTRICT

The Jerome or Verde district of Yavapai county produced about 33,200,000 lb. of blister copper in 1911, as compared with about 38,660,000 lb. in 1910. The production of copper in the district began about 1883, though

ARIZONA.

it had yielded gold and silver previous to that time. Since 1888 it has been a steady and important producer. To the close of 1911 it has yielded a total of 603,200,000 lb. of copper, or 3.68% of the total output of the country since 1845, and 17.2% of the total output of the state. In total output it stands fifth among the copper districts of the country and third in Arizona. In output for 1911 the district ranks eighth among those of the country and fourth in the state.

According to Graton<sup>2</sup> the orebody of the United Verde mine is an irregular lenticular mass, replacing a schistose rock that has resulted from the intense shearing of a rather basic porphyry. The ore minerals, mainly sulphides of iron, copper, and zinc, have partly or completely replaced the rock in some instances; in others, they occur as veins and stringers in the schist. The ores are of pre-Cambrian age. The ores differ from most of the large copper deposits of Arizona in carrying larger amounts of gold and silver. The copper content of the ore is also unusually high for this type of deposit. As little timber as possible is employed in mining on account of the danger from fire. Considerable copper is recovered from the mine-waters that have leached through the burning stopes

<sup>2</sup>Graton, L. C., 'Mineral Resources U. S. for 1907,' Pt. I, 1908, p. 597.

by precipitation on scrap iron. Most of the ore is smelted at the United Verde Copper Co.'s plant. The ore high in sulphur is roasted and smelted in blast-furnaces. Some of the ore low in sulphur is smelted without roasting. The United Verde company has under construction a new smelting plant to replace the one now in use. According to published figures, the United Verde company, the only important producer of the district, made an output of 33,167,987 lb. of copper, 461,145 oz. of silver, and 15,239 oz. of gold in 1911. The precious-metal content was equivalent to about 1.6c. per pound of copper. Development was carried on by other companies in the district during the year, but no important production was made. The district is served by a narrow-gauge railroad owned by the United Verde Copper Co., which connects with the Santa Fé, Prescott & Phoenix railway.

#### GLOBE DISTRICT

The Globe district of Gila county produced about 44,600,-

CONCENTRATOR CANYON, CLIFTON-MORENCI DISTRICT.

000 lb. of blister copper in 1911, as compared with about 27,600,000 lb. in 1910. The increase in production was largely due to the beginning of production by the Miami Copper Co. The mine production for the year considerably exceeded the smelter production, as much of this material had not been smelted at the close of the year. Production of copper began in the district about 1881; the district was well known as a silver producer before that date. For several years subsequent to 1881 the production was intermittent, but since 1888, and especially since 1898, when the railroad first reached Globe, the district has ranked among the important copper producers of the country. To the close of 1911 it has produced a total of 379,300,000 lb. of copper, or 2.31% of the output of the country, since 1845, and 10.8% of the output of the state. In total production the district ranks seventh in the country and third in the state. Important production began in the Miami section in 1911 and this section of the district will continue to grow in importance.

The ores in the Globe end of the district vary greatly in copper content, the grade to be treated at any given time depending largely on the possibility of profitable treatment. In general, ores of as low grade as can be handled with reasonable profit are mined. During 1911 the ores of the district yielded about 3.35% of copper, with about 24c. in gold and silver per ton. The mines of the dis-
